Dr. A. GOODALL said he had found the simile of a bicycle where there was disproportion between pedalling and guiding more easily understood than that of the violin. The distinction between stammering and stuttering was not important. Dr. MEIKLE spoke of the disappointing results obtained by special classes in schools, possibly due to faulty methods of teaching, but largely owing to lack of interest by the pupils. Dr. TRAQUAIR drew attention to a hereditary element sometimes strongly present. There was a natural tendency to cure, greatly assisted by the determination of the patient to cure himself, and also perhaps by the stimulus of ridicule. Professor G. M. ROBERTSON believed that psycho-analysis might reveal some anxiety or fear at the root of many cases, and that the discovery and removal of this would then be the best treatment. This aspect of the question was also dwelt on by Dr. MURRAY LYON and Dr. BROCK.

Cervical Ribs and Pressure Symptoms.

Dr. EDWIN BRANWELL and Dr. H. P. DYKES read a paper on the pressure symptoms sometimes associated with cervical ribs, rudimentary first dorsal ribs, and associated anomalies of the brachial plexus. The subject had become of interest to clinicians in the past twenty-five years, though Sir David Wallace had shown a case to the Society in 1890. There were four groups of cases: visible cervical rib without pressure symptoms; visible cervical rib with pressure symptoms; pressure symptoms, and cervical rib demonstrated by x-ray; and pressure symptoms, with a negative x-ray examination, where, however, there might be a rudimentary first dorsal rib or some anomaly of the brachial plexus. The symptoms comprised supra-clavicular prominence and pulsation, scoliosis, evidence of pressure on the brachial plexus and subclavian artery in unilateral muscular wasting of the thenar eminence and abductor pollicis, pain, and occasional sensory disturbance and diminution of radial pulse. Oedema of arm and hand from venous pressure was very rare. Wood Jones believed the condition to be due to a fault or antagonism between the nervous elements and mesoblastic segments of the upper limb bud, and certainly pressure symptoms occurred without cervical rib. An x-ray finding of cervical rib, therefore, only corroborated the clinical evidence, and the diagnosis could not be based on the x-ray examination alone. The differential diagnosis from peripheral neuritis, progressive muscular atrophy, and syringomyelia was discussed. The condition was much commoner in women. As to treatment, many slight cases required no operative treatment; and rest of the arm and shoulder by sling, and counter-irritation over the brachial plexus were of value. Operation in selected and severe cases was very successful in the relief of pain and occasionally in improvement of muscular weakness.

Sir HAROLD SMILES described the operation. He advised an J incision, the vertical limb along the anterior border of the trapezius, and the horizontal coming inwards along the clavicle; it should be free. Dissection of the parts then proceeded inwards. The greatest danger was injury of the roots of the nerve of Bell which pierce the scapula.

medius close to its insertion. These should be looked for, and the muscle then divided close to its rib insertion. Injury of the pleura was more easily avoided, and if it took place was not serious. He added to the symptomatology the occurrence of chilblains and of pain in the neck from pressure of braces and coats. He suggested that weakness of the trapezius was sometimes a factor in causing the condition.

THE INFLUENCE OF DIET ON THE TEETH.

At a meeting of the London Association of the Medical Women's Federation on February 15th, when Mrs. FLEMING, M.D., was in the chair, Dr. HANDLEY-READ read a paper on "The influence of diet on teeth during the pre-natal period, dental caries, and pyorrhoea alveolaris." She emphasized the importance of accessory food factors as essential to growth, and pointed out how it has been proved that the antirachitic fat-soluble A vitamine was a necessity in diet if the hardest tissue of the body and that requiring the best nourishment—namely, the enamel of the teeth—was to develop properly. The temporary teeth were fully formed in the jaws before birth, though calcification began in the sixteenth week and continued throughout their existence; hence it was evident that the mother's mode of living during pregnancy and lactation must influence the teeth of the child, and her diet must include liberal supplies of fat-soluble A and water-soluble B vitamins. Even at the worst war period the diet of the poorest working woman of this country had just sufficient essential vitamins to produce bone and tooth tissue fairly well calcified, and observations at baby clinics, etc., showed that the teeth of all babies erupted fully formed with apparently good enamel; but if the diet was poor in essential vitamins (antirachitic) the enamel was found carious within a few months.

The infant's diet after weaning, the transition from liquid to solid food, should not be via pap food, as this was bolted without proper mastication and insalivation. By 1½ years of age, with normal dentition a child should be able to masticate an apple, while from 2 to 5 years a child should be capable of masticating any hard food. The County Council classes in their syllabus advised a diet which was almost entirely of pap food, and yet insisted on the importance of mastication!

Pyorrhoea alveolaris was now rampant all over the world among white and coloured races, and was also common in animals kept in captivity. It seemed probable that excessive carbohydrate and deficient antiscorbutic diet largely accounted for this. In true scurvy acute periodontitis was a marked symptom, and the teeth dropped out if antiscorbutic treatment was delayed. Probably modern diet contained sufficient antiscorbutic to prevent actual acute scurvy, but not to prevent chronic periodontitis. We had pyorrhoea because in the mouth we had damaged tissue in the form of inflamed gums, due to pap food; bacteria were always present, and we had a diet deficient in antiscorbutic vitamins. That many vegetarians suffered from pyorrhoea was probably explained by the fact that they were mostly very large consumers of carbohydrates and that their vegetables or fruit were rarely eaten raw. In Asiatic races caries was rare, but the teeth dropped out at middle age in those parts of the country where the antiscorbutic factor was deficient in the diet. Dr. Handley-Read then described several cases in which she found acute pyorrhoea which had completely cleared up on a diet of raw vegetables, salads, fruit, eggs, and a little milk, with very limited carbohydrate. Such an intensive vitaminic diet produced astonishingly good results. While firmly believing in the efficacy of such treatment for chronic periodontitis, local treatment by drugs, vaccines, and irrigation was not to be neglected.

A discussion followed the paper, in which Dr. LEWIN, Dr. HARE, Dr. HARDING, and Mrs. FLEMING took part.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Liverpool on February 18th, with the President, Mr. CARLTON OLDFIELD, in the chair, Drs. GEMMELL and LEYLAND ROBINSON (Liverpool) showed three specimens of uterine fibroids where other complications were present. In two of the specimens the fibroids coexisted with carcinoma of the body of the uterus. In the third specimen a left haematosalpinx was present,

and was evidently produced by torsion, as evidence of ectopic pregnancy. Drs. WILLETT and HENDRY (Liverpool) showed a specimen of hydatidiform mole, with a well-developed four and a half months foetus and placenta. They were of opinion that this was a case of twin pregnancy in which one ovum had undergone vesicular degeneration. Dr. W. W. KING (Sheffield) described a case in which acute symptoms arose during pregnancy from the rupture of a vein on the surface of a subperitoneal myoma of the uterus. At the operation a large quantity of free blood was found in the peritoneal cavity. The tumour was removed by myomectomy and the pregnancy left undisturbed. A discussion took place on Dr. Lacey's paper on induction of labour for moderate contraction of the pelvis, read at the last meeting of the society (BRITISH MEDICAL JOURNAL, February 5th, 1921, p. 195). The opinion of the majority of the speakers was that although excellent results could no doubt be obtained in hospital, as Dr. Lacey's figures showed, the method was extremely tedious in private practice, and apt to cause a good deal of anxiety to the patient and her attendant. Caesarean section should be the operation of choice where there was any reason to fear that delivery of a healthy full-term child by the natural passages was going to be impossible.

Rebicus.

SURGICAL SHOCK.

PROFESSOR G. W. CRILE has rewritten his book on *Anoci-Association*, first published in 1914, but this time it appears under the less intriguing title of *Surgical Shock*.¹ As on the previous occasion, Professor Crile's name is bracketed on the title-page with that of his old and valued friend and assistant, Dr. W. E. Lower. This book, like all Crile's writings, is most stimulating, most provocative, and most speculative. It commences with a frank and interesting summary of the evolution in the Cleveland laboratories of the author's kinetic theory of shock. The many ingenious theories and experiments are here briefly reviewed, but, wide though their scope has been, they have led to negative more often than positive results. Crile has a wide vision, an all-embracing mind, but the issues which he raises, the problems which he has set himself to solve, are too vast for answer by one man. The marvel is that his imagination has been so fertile in suggesting new theories each time that he has had regretfully to abandon the old. In spite of the supreme difficulties of his task, Crile has succeeded beyond anyone else in suggesting methods of combating an entity which neither he nor others are able convincingly to explain. He is above all a man with a passionate belief in his cause. His intense enthusiasm has won him a host of converts and disciples. Yet those who hold themselves aloof from his influence will have little difficulty in finding faults in his work. His photographs, for instance, of exhausted tissue cells are either accepted as part of the faith or are gazed at with sceptical and agnostic eyes. "Where," the unbeliever asks, "are the detailed records of these countless experiments? How often has this particular experiment been performed? Is not such and such a histological appearance within the limits of the normal?" We are informed that upwards of 3,000 animals and men have been histologically examined. A life-work indeed!

Crile's detailed work is vulnerable, but his general kinetic theory of shock is extraordinarily ingenious and seductive. It has enabled him to elaborate and to perfect methods of preventing shock which will probably ensure the handing on of his name to posterity. With the knowledge that general inhalation anaesthesia does not prevent an animal from receiving subconscious painful impressions, and the knowledge that stimuli of sufficient number or intensity cause exhaustion and may cause death, Crile set himself to find a technique which would reduce the noxious impulses to a minimum. This technique he now calls "Association," a handier word than the former "Anoci-association." Crile's credo is embodied in this passage:

"The one great exciting cause of surgical [operation] shock is the surgeon—every contact of his instrument with an unanaesthetized nerve-ending, nerve filament, or nerve-fibre;

¹ *Surgical Shock, and the Shockless Operation through Anoci-Association*. By G. W. Crile, M.D. and W. E. Lower, M.D. Second edition of *Anoci-Association*, thoroughly revised and rewritten. Edited by Amy F. Rowland, B.S. Philadelphia and London: W. B. Saunders Co. 1920. (Roy. 8vo, pp 273; 75 figures. 21s net.)

every drop of blood which he sheds; every moment he requires the continuation of inhalation anaesthesia; every moment he exposes sensitive tissue to the air; every interference with adequate ventilation of the lung; every thrill of fear he introduces into his patient—each of these is an exciting cause of shock, and the combined result of all may be death."

The "anociative" technique requires no special apparatus; it is within the power of all surgeons to apply. We venture to assert that few who do employ Crile's methods will fail to gain greatly for their patients and themselves. Something of value has been added to surgery, and we are Professor Crile's (and Dr. Lower's) debtors.

There are no radical changes in this second edition, but there is a general improvement in the chapters describing individual operations. We note that urea hydrochloride is now used very cautiously and only on special occasions.

Dr. Geoffrey Marshall, some of whose charts are reproduced, is incorrectly referred to as Dr. Gregory Marshall.

ANTISEPSIS AND ASEPSIS.

DR. CHARLES SINGER of Oxford, lecturer in the history of medicine at University College, London, is editing a set of volumes which, under the general title "Medical Classics Series," is to be published by Messrs. John Bale, Sons, and Danielsson. The object of the series is to reproduce some of the most epoch-making contributions to medical science. Each volume will be complete in itself, and each will contain a brief note on the author's life. The first volume² consists of *Six Papers by Lord Lister*, selected by Sir RICKMAN GODLEE, who has written a short biography and added a few explanatory notes to the papers. The biography, as was to be expected, is very well done; in the course of it Sir Rickman Godlee takes occasion to discuss what he rightly calls the thorny subject of aseptic surgery, as opposed to antiseptic surgery. He points out that aseptic surgery, as it is now understood, was almost from the first Lister's ideal; he tried to adopt it as early as 1868 and on other later occasions, but he did not persist in the attempt because he thought that antiseptic surgery was equally efficient and more easily carried out. It is pointed out that the principle underlying the two methods is identical, the object of both being to prevent the access to a wound of pathogenic micro-organisms in such a condition or in such numbers that they have a chance of living and of propagating themselves. In the earliest days Lister thought he had succeeded in keeping germs out of wounds altogether, but afterwards it was shown that complete exclusion was rarely attained, was sometimes impossible, and not really essential. In rendering their applications free from germs aseptic surgeons trust more to heat and less to chemical substances than Lister did, but since the importance of the skin as the source of wound infection has been realized, antiseptics have been used both for the skin at the site of operation and for the surgeon's hands.

The volume contains six essays; the first the paper on the early stages of inflammation, communicated by Lister to the Royal Society in 1857; the last the address on the present position of antiseptic surgery which he delivered before the International Medical Congress in Berlin in 1890. Among other essays is Lister's report of the demonstrations of antiseptic surgery he gave before the British Medical Association at its annual meeting in Edinburgh in 1875. The volume is illustrated by a reproduction of a well known photograph of Lister when about 60, and of an early photograph of Lister and his wife; there is also a facsimile reproduction of a letter by Lister written in 1861 to his father.

THE SPHYGMOMETER IN PRACTICAL MEDICINE.

PROFESSOR W. RUSSELL of Edinburgh, who has written much on arterial disease in his monograph *Arterial Sclerosis, Hypertonus, and Blood Pressure*, at present out of print, as well as in numerous papers, now publishes, under the title *The Sphygmometer: Its Value in Practical Medicine*,³ his George Alexander Gibson Memorial Lectures

² *Six Papers by Lord Lister. With a Short Biography and Explanatory Notes by Sir Rickman J. Godlee, Bt., K.C.V.O., M.S. Medical Classics Series. 1921. London: John Bale, Sons, and Danielsson, Ltd. (Crown 8vo, pp. vii+194. 10s. net.)*

³ *The Sphygmometer: Its Value in Practical Medicine. By William Russell, M.D., LL.D. London: Baillière, Tindall, and Cox. 1921. (Demy 8vo, pp. 157; 14 figures. 7s. 6d. net.)*

for 1920, appropriately dealing with a subject in which his late colleague took so much interest, and also eight papers that appeared between the years 1903 and 1917. These pages contain a clear exposition of very definite opinions based on many years of clinical observation. The view that the sphygmometer gives the true brachial blood pressure, and that 5 mm. Hg only need be allowed for the vessel wall, whatever its condition, is strongly opposed by the author, who has always contended that thickening of the arterial wall from sclerosis, from hypertonus, or from hypertonus in a sclerosed artery, is the important factor in sphygmometer readings. The sphygmometer is of great value in demonstrating the relaxation and contraction, or the play of tonus, in thickened arteries, and sphygmometer readings should not be regarded as providing an assured record in terms of "blood pressure." Another point that is firmly emphasized is that sclerosed arteries are not necessarily or even usually athromatous, and that the sclerosed artery seldom, if ever, becomes a rigid tube. Arterio-sclerosis is defined as a uniform thickening of the middle coat of the arteries in their whole length, whereas atheroma occurs in patches and, like calcareous infiltration, is comparatively rare in the radial artery even of old people. Hypertonus is described as occurring both as a prolonged and as an off-recurring increase of the normal degree of contraction of the arterial muscular coat which is physiologically called tonus; further, hypertonus, though raising the sphygmometric reading, implies a diminished quantity of blood in the vessel and a fall of the blood pressure inside it. Cases showing the association of hypertonus with migraine, cardiac distress, anginoid symptoms, excess in tobacco, and epileptoid attacks are given. Disordered gastric function may cause hypertonus, which is removed by purgation, and the importance of gastro-intestinal disturbance in the production of arterio-sclerosis is emphasized. Dr. James MacDougall is quoted to the effect that enlargement of the prostate occurs only or mainly in persons with well-marked arterio-sclerosis, and it would be interesting to have heard some discussion on the question whether there is any real relation between these two changes so common in advanced life, or whether the association is analogous to that of baldness and arterio-sclerosis.

PHARMACOGNOSY.

THE second edition of Dr. KRAEMER'S *Scientific and Applied Pharmacognosy*⁴ follows the first after an interval of five years. The greater part of the book is devoted to descriptions of crude vegetable drugs arranged according to the natural relations of the plants from which they are derived, but a few of the more important animal products are also considered. The sources, constituents, and commoner impurities of each drug are fully treated and the literature is adequately cited. One of the more prominent features of the work, and especially of this edition, is the author's wide view of the scope of his subject. The implied definition of pharmacognosy as the study of raw materials and the products manufactured from them will be considered too inclusive by many, but the strongly expressed opinion that pharmacognosists must have at their command, and be able to apply practically, a number of widely different branches of science must be accepted. Not only is a sound general knowledge of such subjects as chemistry and botany needed; highly specialized departments of these also find application. Among the problems requiring the applications of plant physiology are the relations of soil and climatic conditions to the variations in the constituents of drugs, and we should be on firmer ground here if we knew more of the part played by alkaloids, glucosides, and the like in the economy of plants. In approaching the subject of the cultivation of medicinal plants we are confronted with the problems of hybridization and mutation. Systematic experiments in drug cultivation have received increased attention of late, especially in America, and the results so far obtained seem to show that soil and weather have relatively less influence upon the yield

⁴ *Scientific and Applied Pharmacognosy. Intended for the Use of Students in Pharmacy, as a Handbook for Pharmacists, and as a Reference Book for Food and Drug Analysts and Pharmaceutists. By Henry Kraemer, Ph.D., etc. Second edition. New York: John Wiley and Sons, Inc. London: Chapman and Hall, Limited. 1920. (Med. 8vo, pp. 748; over 300 plates, comprising about 1,600 figures. 33s. net.)*

of active principle than has the individuality of the plant; hence the best results have been obtained by seeking out the better individuals and propagating from these. By this method it has been found possible to increase considerably the yield of alkaloid given by such plants as belladonna. As a nation we cannot claim to have been particularly progressive in these matters, but the effort now being made to increase the area of cinchona plantation in India, with the object of rendering that country capable of supplying the whole of the British Empire with quinine, is a step in the right direction. We note that attempts are being made in America to standardize certain drugs by observing their toxic action on germinating seedlings.

Dr. Kraemer emphasizes the application of chemistry to micro-analysis and to the elucidation of the little understood fermentative and other changes which take place in the drying and maturing of drugs. Many new and important applications of physical and crystallographic methods are also cited. To the scientific equipment of the pharmacognosist as recommended by the author we would add a knowledge of zoology and animal physiology, in view of the increasing number of animal substances now being employed in medicine. The outcome may be that in pharmacognosy, as in many other subjects, the bulk of the advances of the future will result from the team work of specialists rather than the efforts of individual investigators. The volume before us is furnished with excellent and abundant illustrations, those dealing with microscopic structure being particularly good. The book is one of the best of its kind.

HUMAN ANATOMY.

New manuals of human anatomy are not uncommon, but Professor PITZMAN'S *Fundamentals of Human Anatomy** deals with the subject in a manner which is, in many ways, original and deserves serious consideration at the present time, when the reconstruction of the medical curriculum is giving rise to much discussion. It is possible that, in the near future, less time will be devoted to the study of human anatomy in the pre-clinical period, although this may be balanced by more extended courses of applied anatomy, running throughout the clinical period of study. Should such a change come about, it would be found that most of the existing textbooks contain much more detail than it would be advisable for the student to attempt to absorb in the time at his disposal, and that a manual on similar lines to Professor Pitzman's would be essential.

The author rightly emphasizes the very intimate relations which exist between anatomy, physiology, pathology, and the clinical subjects, and expresses the belief that anatomy can be taught most efficiently by constant references to its applications. It may be admitted that the author's aims are in every way praiseworthy and deserving of support, but approval cannot so readily be accorded to the manner in which these aims have been carried out. It ought to be possible in a book of this size to include all facts of human anatomy which are likely to prove of value to the average practitioner in his daily work, but much of this information has been excluded. Particularly is this true of the central and peripheral nervous systems. It is unfortunate that this defect is not compensated for by the soundness of the teaching in other respects. The movements of the knee-joint and the functions of its crucial ligaments are not described in accordance with English views, and such statements as "the clavicle is bound down firmly . . . by the coraco-clavicular ligament" convey a quite erroneous impression of the function of that ligament.

When we come to the choice of particular examples to illustrate the applications of anatomy to medicine and surgery, there must always be a difference of opinion as to relative values, and it would be unfair to cavil at the examples selected. Such instructions for dissectors as are included are very brief, and a student dissecting his first "part" would not find them very helpful. It would have been wiser to have omitted the instructions altogether than to have included them as they stand.

Despite such criticisms as have been offered, the fact remains that the book is an endeavour to show that

human anatomy, as taught in the pre-clinical period of medical study, can be made simpler, more generalized, and more helpful. At the same time, it must be remembered that such a method of teaching the subject can only prove satisfactory when it is supplemented by a series of courses on applied anatomy during the clinical period.

NOTES ON BOOKS.

THE late Sir CHARLES A. CAMERON, of whom an obituary notice appears this week at p. 405, was born as long ago as 1830. In his *Autobiography*,¹ which appeared a short while ago, there are many interesting stories and reminiscences told in a genial and breezy style. His earliest recollection was that of a very old woman who, eighty-eight years before, had seen part of the battle of Culloden (1746). Though born in Dublin, he belonged to the Lochell branch of the Clan Cameron, and there are several anecdotes of the amusing confusion that occasionally arose between him and his *alter ego*, as he called him, Dr. (now Sir) Charles Cameron, M.P. for the College Division of Glasgow. The author, after sixty-five years of dinner parties, formed the conclusion that such pleasant reunions were conducive to longevity. In 1852, when 22 years old, he became a professor of chemistry, ten years later he was elected public analyst, and in 1874 medical officer of health to the City of Dublin, a post that he held until his death. He had also been professor of chemistry to two other bodies in Dublin as well as for a time professor of anatomy to the Royal Hibernian Academy, of which he was an honorary member. The appreciation in which he was held is incidentally shown by the number of presentations made to him.

The first part of the *Kystoskopischer Atlas*,² produced by Dr. med. ERICH WOSSIDLO, is devoted to a description of various forms of cystoscopy; the author apparently favours the Nitze instrument, and for catheterization of the ureters the special instrument of Rieglieb; other forms are not discussed. Following this is a brief description of the technique of cystoscopy; the remainder of the text deals with the various abnormal conditions which may be found in the bladder, with brief notes on their pathological anatomy, their etiology, diagnosis, and methods of treatment. The chief value of the work lies in a series of coloured plates (thirty-eight in all), each plate containing some four or five cystoscopic views. These illustrations are, on the whole, of a high order and cover a very large range of subjects.

It is not surprising that a second edition of Dr. C. PRICE-JONES'S handy and clearly written introduction to clinical haematology entitled *Blood Pictures*,³ first published in 1917, has been called for. In a small space it gives the maximum amount of information for the interpretation of blood counts, and is accompanied by five admirable coloured plates, which should, together with the technical directions in the text, provide an invaluable guide to house-physicians and clinical clerks. The leucocytes are divided into the leucoid or granular, the lymphoid or non-granular, and abnormal cells, degenerated and immature, and there is a phylogenetic diagram of the blood cells facing a coloured plate of the marrow cells for comparison. Dr. Price-Jones points out that, broadly speaking, a leucoid type of blood is associated with a coccic infection, a lymphoid type of blood with a bacillary infection, and a lymphoid *plus* a large mononuclear type with a protozoal infection. Twenty blood counts are given, and their diagnostic significance are discussed in the light of an extensive experience. Arneith's count is not referred to by name, but the author remarks that a classification of the polymorphonuclear leucocytes based on the number of their nuclear divisions has little practical bearing. An appendix contains a summary of the author's recent work on the diurnal variations in the size of the red cells.

THE widow of Professor Cozzolino has recently presented to the oto-rhino-laryngological clinic of Naples the rich collection of anatomical and pathological specimens collected by her late husband.

THE FUTURE OF RESEARCH IN TROPICAL MEDICINE.

SIR LEONARD ROGERS, C.I.E., M.D., F.R.S., delivered his presidential address before the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on February 24th. After referring to the organization of the new Section, and the choice of its title to prevent confusion with the earlier established Society of Tropical Medicine and Hygiene, and to the opportune bequest to the Royal Society of Medicine of the very valuable Chalmers library of tropical medicine, Sir Leonard Rogers said:

I wish to take advantage of the present opportunity to say a few words on the future of research in tropical medicine mainly from the point of view of what this country, and especially this, the wealthiest city of the world—much of whose prosperity is derived so largely from trade with tropical and sub-tropical countries—can and should do for the advancement of what may safely be called the most rapidly progressing and life-saving branch of medical science. We all know the great part the Schools of Tropical Medicine of London and Liverpool have played, both in training so many post-graduates and fitting them to undertake researches in various tropical countries with most beneficial results, as illustrated, for example, by the work of Castellani in Ceylon; and also in sending numerous research workers abroad for limited periods to tackle various problems, such as the pioneer work of Dutton and Todd from Liverpool in the dark continent of Africa; Manson-Bahr's all too short expeditions to study dysenteries in Fiji and sprue in Ceylon, and Leiper's brilliant solution of the life-history of bilharzial parasites in Egypt, both from the London School of Tropical Medicine, to mention only a very few.

While fully admitting the value of the work done by such brief expeditions of research workers to tropical countries, my own work not unnaturally leads me to consider whether the time has not come to modify to some extent the policy hitherto pursued by our English tropical schools, which is also that of the Tropical Diseases Committee of the Royal Society, so fully justified in the past by the brilliant researches of Sir David Bruce and his fellow workers at the very serious problem of the spread of sleeping sickness in Africa with the opening up of trade routes. Any value my own researches may have is solely due to my good fortune in being able to carry out long-continued and patient investigations in a tropical country in a laboratory in the closest possible association with a wealth of clinical material at the Calcutta Medical College Hospital with its 600 beds, for the last twenty years, with three intervals of a few months' leave home. I was thus led to the conclusion that Calcutta presents the finest opportunities for a great school and research laboratories of tropical medicine in the world, and I have devoted much time during the last ten years to organizing such an institution, which has already commenced research work, and will by next October be fully staffed for teaching as well. To this institution a hygiene section, for which the laboratory accommodation is already provided, will be added as soon as final sanction is obtained, when the services of ten Government professors will be available with about three-fourths of their time for research. Further, the response to an appeal I issued several years ago for funds to build a special hospital for 116 beds for tropical diseases and to support additional research workers has been so liberal that at the present time, at the official rate of exchange (which unfortunately is at present considerably over the market rate), over £100,000 has been subscribed, together with such large annual contributions that, after building and equipping the hospital, an income of £12,000 a year is already assured for research.

The largest contributions to the hospital have come from Indian rajahs and merchants, and those for research from English business men and firms, including very liberal support from Sir David Yule and Sir Dorab Tata. Seven whole-time research appointments, two of which are held by Indian research scholars, are being financed from this fund under a committee of medical men. As each worker has one or more qualified Indian assistants, the total staff will number forty-two, while the completed laboratories consist of four floors, with 220 ft. of north light, connected by a small foot-bridge with my former laboratory and museum, giving a total north front of 400 ft. I mention these facts to show what Calcutta has done for tropical medicine, and will only add that in my appeal I asked for money as a business proposition, and was able to persuade many of the donors that it would pay them to give money to investigate the tropical diseases such as

ankylostomiasis, which so severely handicapped their labour forces. Another school on similar lines has also been organized in Bombay by my friend Lieut.-Colonel Glen Liston, I.M.S., which, together with the four hill-top laboratories of the Bacteriological Department of the Indian Medical Service and the Pathological Laboratories of the Medical Colleges, will place India in the forefront of research in tropical medicine.

Having thus been privileged to have a share in the organization of medical research work in India on practical lines, with the closest possible relationship between clinical and pathological work—an important point which, I venture to think, is not always sufficiently borne in mind in this country—I cannot help inquiring whether sufficient provision for similar work has yet been made in other British tropical possessions, and, if not, what steps are necessary to remedy such a serious deficiency. Something has, of course, been done in the last two decades, with practical results which should surely lead to world-wide further efforts in this direction, such as the discovery of the cause and means of prevention of beri-beri in the Malay States, where the Kuala Lumpur laboratory has furnished such good work; the Wellcome Laboratory of Khartoum under Balfour, from which town Christopher-son's tartar emetic cure of bilharzial disease has emanated; the valuable work of the Queensland laboratory under Breinl, and that of Macfie in West Africa, where the Sir Alfred Jones Tropical Laboratory is being built at Sierra Leone. But what are they among so many, save as crying appeals to the wealthy to emulate the example of such practical philanthropists as Mr. Wellcome and Sir Alfred Jones? I understand that such an important colony as British East Africa (to mention only one striking example), where white men can flourish and many of our out-of-work soldiers might well find a livelihood with some initial help from Government, has neither laboratory nor research worker, although the neighbouring Uganda Protectorate is slightly better off.

A few months ago I received an invitation to join an influential Committee for the Prevention of Tropical Diseases, but on learning from their circular that they proposed to spend £30,000 on a single expedition to a very small and rather healthy (because malaria-free) West Indian island, I felt obliged to decline the invitation as I could not agree with such a policy. But I intimated that should they at any time alter their policy to one of organizing permanent research laboratories in various British tropical possessions I would gladly do anything I could to help them, and that is the policy I now desire to put forward for the consideration of those interested in the progress of tropical medicine. The Liverpool school have already given a lead in the right direction by establishing research laboratories at both Sierra Leone and at Manaus, in Brazil, and I trust that the much more wealthy City of London will not lag behind in such practical work, but will find liberal sums to enable the London School of Tropical Medicine, if they approve of the policy I suggest, to found research laboratories in British East Africa and other British tropical countries which are at present without such vitally important institutions. If money is forthcoming, and the support of the Colonial Office can be obtained, I would suggest that annual contributions towards the support of a research worker for a limited number of years should be offered to selected British colonies on condition that the local authorities supplied a small and unpretentious laboratory to start with immediately adjacent to the largest available hospital, and I have no doubt whatever that, after five years' experience of the benefits derived from it, they will be only too glad to grant it full permanent support, thus setting free the home grant for similar use in some other country. It should be a condition of the grant that the organizing committee should have a say in the appointment of the investigator, to ensure the right man being obtained for the critical first five years, which should, I suggest, be the shortest time any research worker should go abroad. This plan would in time assure all important British tropical possessions obtaining permanent laboratories and research workers, while it will still be possible, and occasionally advisable, to send temporary expeditions of specially qualified investigators to tackle some urgent problem due to an epidemic disease or an especially technical problem such as schistosomiasis was but a short time ago. The old policy of trusting entirely to temporary inquiries, with heavy costs for equipment and passage, and leaving no permanent organization behind the pioneer to carry on the work they have begun, should be abandoned as far as possible.

I trust I have made it quite clear that I am not criticizing the earlier policy, which was doubtless correct in the first stages of the evolution of our home schools of

tropical medicine, but I do wish to suggest, in the light of my long Indian experience, that the time has come for the further advance I have indicated. Indeed, I think this has been necessitated by the very success of recent researches in this field, including all the work done on dysenteries during the war, for now so many of the simpler problems have been solved the remaining problems of tropical medicine will require much more prolonged and detailed inquiries, including team work, such as is being provided for in the Calcutta school, the liberal public support of which would serve as a stimulating example to London philanthropists, and especially to those whose firms or companies trade with tropical countries. Their young assistants have to live in such climates exposed to unnecessary dangers to their health from the lack of the safeguards provided by research laboratories, and I appeal to their employers for support for the proposals I have ventured to bring forward.

PREVENTION OF VENEREAL DISEASE.

At a conference on the prevention of venereal disease, under the chairmanship of Lord ASKWITH, on March 1st, Dr. MEARNS FRASER, M.O.H. for Portsmouth, proposed:

"That, in view of the terrible effects of venereal diseases on the health of the nation, and especially because of their effects upon women and children, there is urgent need for health authorities to institute active measures to protect the inhabitants of their districts against these diseases. Of these measures, by far the most important is education of the public as to the dangers of venereal diseases, as to the manner in which they are spread, and, above all, education in the methods of immediate self-disinfection, by which venereal diseases can be largely prevented."

He said that the Society for the Prevention of Venereal Disease was anxious to induce local authorities to make known the methods of self-disinfection to the public. He considered the time was ripe for local authorities to take action on the lines adopted by Portsmouth. The resolution was seconded by Dr. CHARLES SAUNDERS, M.O.H. for West Ham, who said that there were resolutions on the minutes of the West Ham Council approving of the education of the people in immediate self-disinfection.

Dr. E. W. HOPE, M.O.H. for Liverpool, stated that he was heartily in accord with the views expressed by Dr. Fraser, and gathered that, when emphasizing this aspect of the question, other aspects would not be lost sight of. He thought that those who raised objections from the moral standpoint seemed to forget that no obstacles were being placed in their way.

The Mayor of Portsmouth said that the inhabitants of Portsmouth had all now come round to Dr. Fraser's way of thinking, and he had had all the support which any medical officer of health could wish for on this subject.

Dr. BOND, M.O.H. for Holborn, said that Holborn was the first London borough which had adopted the method advocated by the Society for the Prevention of Venereal Disease; he considered this method of education inexpensive. Dr. HOLROYD, when he brought the question

disinfection before his Health Committee it was unanimously supported by them, and there was not a single dissentient, nor were any dissentient opinions expressed in the town.

Mr. THOMPSON, Chairman of the Health Committee, Liverpool, said that during the past year they had had 78,000 attendances at the Liverpool venereal clinics, and emphasized the necessity for continuity of treatment. Mr. WHITWORTH, Chairman of the Bedfordshire Venereal Committee, considered it necessary to amend the Venereal Disease Act, 1917, so as to enable anyone to go to a chemist and ask for what he wanted.

The resolution was supported also by Dr. J. B. HOWELL, M.O.H. for Hammersmith, and Dr. VEITCH CLARK, M.O.H. for Croydon.

The CHAIRMAN then submitted the following addendum to the resolution:

"Resolved further that this resolution be adopted by health authorities through request that they take the

With this addition the resolution was then put to the meeting and carried unanimously.

Lord WILLOUGHBY DE BROKE, President of the Society for the Prevention of Venereal Disease, moved a vote of thanks to Lord and Lady Askwith. Dr. WANSEY BAYLY, the Honorary Secretary, who seconded, said that he had just received a telegram from Dr. J. Priestley, M.O.H. for Lambeth, expressing cordial support of the resolution, and that Colonel [unclear] of the Society of Medical [unclear] to be present, unless prevented

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

MINISTERIAL AND COMMERCIAL ASPECTS.

It is not good news that the Ministry of Transport, which has scarcely been got into working order, is to lose its head, Sir Eric Geddes, next summer. Whether the Ministry itself is to lapse is apparently still undecided. In all likelihood its functions will be absorbed by one of the older ministries. This at least is certain, that once a Government has regarded the question of internal transport as a national affair it will not be allowed to revert to the condition in which it was the sport of local authorities. All that motor owners and builders can do in the meantime is to be forewarned that a very sharp look-out will have to be kept on the money raised from them by way of taxation. Unless we see to it very carefully an increasing portion of the net sum raised from motor taxes will begin to be diverted to other ends. Already there are signs that at no distant date the bulk of the motorists' money spent on the roads will not be employed to give us twentieth-century highways and byways for twentieth-century traffic, but merely to patch up and keep going obsolete systems; in other words, to pursue the work of maintaining unsuitable road types which, among other things, are enormously wasteful when employed for latter-day traffic. In the current year far too small a proportion of the money is being spent on that work of permanent road improvement which should be the main objective of all endeavour. There are indications that that work may be so limited in ultimate scope that, in relatively a few years, all that will be held necessary will have been accomplished in that connexion; apparently the idea is that the total amount of funds then supplied yearly by motorists by way of taxation will be employed solely for maintaining the highways and not to remodel them. This should not be allowed. Among the points that concern motorists and are under consideration by the Government at the moment, is the question of the left-side drive. It has been condemned by many coroners throughout the country as being dangerous. It cannot be said that anything has happened this year which has not tended to confirm that danger, particularly as concerns the use of left-side driven vehicles wherein the driver is enclosed by covered coachwork. The draft of the promised new bill to deal with speed on the highways and so on will either undergo modification before introduction to the House, or it will prove a very unpopular measure there.

PRICES.

The first motoring development of the year has been the inevitable and long-expected campaign of price cutting, chiefly on the part of those who have produced car types which are little better than furnished up pre-war models. This move has been countered by those who produce cars for which there is a demand. Such firms have given undertakings to the effect that, should there be any fall in the price of their vehicles as between now and June or July, as the case may be, any buyers placing orders to day will receive a rebate of any such difference in price. But it must be understood clearly that it is impossible for the cars which are in most demand to be sold at lower prices than are ruling. Already the price of many of them is too low from the point of view of the accountants of the manufacturers. Moreover, where genuine post war designs are carried out with post war material and by post war manufacturing methods it is not possible to reduce prices, though these may appear dear. The reason is that such designs call for very expensive methods of production with the view to making motoring more economical. This was admirably illustrated last week when Vickers' motor manufacturing concern, the Wolseley Company, invited the Press to inspect its works after an interval of seven years. During that period the original shops at Adderley Park, Birmingham, have been expanded to a floor space of thirty three acres, and entirely new works for the production of the 10-h.p. four cylinder, overhead valve engine. Three speed Wolseley (ex-Stellite) car have been set up with a floor space of sixty-six acres at Ward End, a couple of miles away from the parent shops. Though at the first glance the machines are apparently not cheap, a consideration of

Owing to the increase of poverty in Austria, an insurance society has been founded at Vienna for members of the middle classes under the name of the "Yellow Cross." Those insured have the right to choose their doctor, and in operation cases their surgeon, as well as their hospital or nursing home.

the quality and features embodied in them reveals that they can compare favourably with the cheapest home or foreign-produced vehicle under the heading of bare cost at the end of two years. That is to say, real post-war designing ensures a big economy in running and maintenance costs.

REAL MOTORING ECONOMY.

In the case of the 10-h.p. car the tax is about £11 a year, yet each engine has to pass a bench test of 24.25 h.p., and with such a vehicle it is possible, without ever exceeding forty miles an hour, to average thirty-two miles an hour from point to point in long runs when driving in an ordinarily cautious way and without "hunting" the car. These engines are guaranteed to give thirty miles to the gallon of fuel, and I make bold to foretell that within six weeks the cars will be selling with a guarantee that the engine will accomplish forty miles to the gallon. Thus the owner saves both in petrol, which is costly, and in engine tax, which is a substitute for the petrol tax obtaining last year. How this is done may be illustrated by taking the mean effective pressure of this engine compared with the average of standardized type. The mean effective pressure means the motor fuel supplied to the engine and turned into horse-power. In the case of the popular American type of car a mean effective pressure figure of 78 is about the average, and 85 would be a fair figure for most British and Continental standard cars, whereas in the case of the Wolseley post-war engine it is 110, a figure better than was obtained with the former cars specially built for the Tourist Trophy Races before the war. It is, however, one thing to aim at employing a much better engine—in which connexion the firm has just standardized battery ignition sets for these types—and quite another matter to evolve such an entirely new chassis as shall represent a car which is 100 per cent. post-war design, instead of merely placing a post-war type of engine in a pre-war chassis. The Wolseley coachwork, as well as the chassis, is made on new lines. In this little car the back axle and the engine form in effect the frame of the vehicle. Another point about which the non-technical are often puzzled is how a machine having quarter elliptic front springs and no radius rods would fare in the event of the main leaf of a front spring breaking. A glance at the construction employed will reveal that there is a short dummy leaf with an eyelet hole underneath the main spring leaf. This dummy leaf does no work when the car is in normal condition. But the eyelet hole of this abbreviated dummy undermost leaf is attached to the shortest and uppermost spring leaf proper by a shackle. Thus it is possible to saw through the leaves of the spring—I doubt if they have ever been broken, for they are proportionately strong—and still drive at forty miles an hour with perfect safety with a spring thus artificially broken. This simple detail is the subject matter of a master patent, a fact of which some rival manufacturers appear to be unaware, in that they are standardizing this so simple and effective solution of a very difficult engineering problem.

THE SCIENTIFIC USE OF PLANT.

This car, together with the 15-h.p. £16 tax model, the engine of which is tested to give 45 to 46 h.p., is of particular interest to the medical man by reason of the low running costs. The springing system common to both results in a set of tyres being good for at least a year's work under average conditions. The economy, without sacrifice of the distinctive qualities of rapid acceleration and good hill-climbing, is accounted for mainly by a combination of three factors. The first is the even torque of the engine at all speeds and loads, for these are very high-grade engineering constructions; the second is the smoothness of the clutch and of the worm drive; and the third, of course, is the exploitation of the special form of springing which is perpetually plangent, and with which it is impossible to get a jar, the most that can be experienced being a plunge. The wheels follow the contour of the road, so do not jump and spin, with consequent grinding. Throughout the engine and the chassis of both types workmanship to exceedingly close limits is made possible by the war experience, which, in part, is continued by the Wolseley production of screw gauges, not merely for its own works but practically for the supply of the entire British industry and for export. Every one of those

gauges is made by a girl at a machine a little larger than a sewing machine, yet every gauge so produced has to pass the National Physical Laboratory tests, which require it to be accurate to within one ten thousandth part of an inch in each of seven elements in which it is measured photographically. In short, there is here no manufacturing of cars by hand. Every part of the work is sectionized. There are two laboratories on the establishment, for, apart from that concerned with experimental work, every piece of raw material used is tested. Judged by the pre-war scale of British motor production the experimental department itself would be quite a considerable factory. Practically every make of car in a range between 8 h.p. and 50 h.p. is tested, so that the data obtained in connexion with it are available in comparative form.

100 PER CENT. EFFICIENCY.

The firm does its own stamping. In these vast factories there are made not merely the aluminium, but the steel castings for cylinders, and for every part of a car which is ordinarily bought from outside, including, for example, the back axle details. By the multi-jig principle it is possible to machine a couple of dozen crankshafts in synchronism to the gain of absolute standardization as well as of great economy, because by that means 100 per cent. cutter efficiency is obtained; that is to say, instead of only a twenty-fourth of the total movement, every inch of the travel of the machine under the tool produces cutting. In the huge pressing department approaching completion at a cost of £120,000 odd it will be possible to reduce by one-tenth the combined cost of materials and labour for a set of wings for a car. This plant, besides, will press under pans for chassis, body panels, and so forth. A track assembly system is available when wanted. But the firm has not yet accelerated to full time, though it is turning out 150 cars a week already, for every one of which a retail purchaser has been secured by one of the firm's agents. The delay in the production programme is due to the disastrous effects of the twenty-two weeks' moulders' strike, which cost a full years' output, because such a dislocation is always of much longer duration than the prime cause of it. The capacity of the Ward End works for turning out the 10-h.p. Wolseley car is 10,000 cars a year. If a night shift is put on in the machine shop, between the two factories it will be possible to turn out, among the three models, 24,000 cars a year; there is a 20-h.p. six-cylinder side-valve engine type. The normal day shift production of the two factories is 12,000 cars. The organization is such that output can be accelerated very rapidly now. On the other hand, it is not necessary to accelerate beyond the present output should the Government be able to do nothing in regard to the exchange situation, which is handicapping foreign trade.

The 10-h.p. model is made with a two-seater coupé body as a permanently closed car, which is, nevertheless, airy in warm weather. A two-seater model on the same type of chassis is furnished with Cape cart hood elaborated on such a scheme that, in bad weather, a doctor can make a completely and effectively rainproof motor-carriage of it. The firm announces that there can be no price reduction this year; but it undertakes to prove by figures that its car can compete favourably on combined purchase and running cost on a two years' running basis with any vehicles in the market. Of course, at the end of two years a machine made to such very fine limits of materials of such quality would be practically none the worse for wear; whereas the life of most cheap-for-their-size cars is brief. An interesting sidelight is furnished by the fact that one of the largest and foremost engineering houses in Japan has taken out a licence to make these cars, the patent laws of that country rendering that the only means of safeguarding such unique constitutional features.

As illustrating incidentally how closely the prices of the highest classes of small cars are coming to those of the best quality motor bicycle and side-car outfits attention may be drawn to the announcement that the Rover Company has reduced the price of the 8 h.p. twin-cylinder air-cooled Rover car complete from £207 to 250 guineas. This is a vehicle with motor cycle scale of tyre upkeep and fuel consumption, yet with the advantages of a car from the points of view of riding accommodation, protection against the elements, the possession of three forward speeds, worm drive, plate clutch, and plangent quarter elliptic fore and aft springing.

British Medical Association.

PROCEEDINGS OF COUNCIL.

A MEETING of the Council was held at 429, Strand, London, W.C., on Wednesday, February 16th, 1921, with Dr. R. A. BOLAN in the chair. There were present:

Sir Clifford Allbutt (President), Representative Meetings, Bailey (Staffs), Dr. J. A. E. Pool (Dr. J. W. Bone (Lut.), H. C. Bristowe (Wringlor), Coombe (Exeter), Dr. J. Singleton Darling (Luton), Dr. James Don (Newcastle), Dr. R. Langdon Down (Hampton Wick), Mr. W. McAdam Eccles (London), Lieut. Col. R. H. Elliot, Dr. A. C. Farquharson, M.P. (London), Dr. A. Forbes (Sheffield), Dr. E. R. Fothergill (Hove), Dr. R. A. Francis (London), Dr. J. Goff (Windsorham), Mr. N. Bishop Harman (London), Dr. I. W. Johnson (Bury), Dr. D. Lawson (Banchory), Sir R. H. Luce (Derby), Dr. J. A. Macdonald (Taunton), Dr. S. Morton MacKenzie (Dorchester), Major General Sir William ...

The Council resolved to send a special letter to Sir Dawson Williams, Editor of the *BRITISH MEDICAL JOURNAL*, expressing its gratification that the Editor's services to the medical profession, medical journalism, and the community had been recognized by the King. Congratulation on their knight-hoods was conveyed also to Sir Squire Sprigge, Sir Charles Ryall, Sir William Hodgson, and Sir Alexander Jarvie Hood.

Dr. Macdonald's Visit to South Africa.

The Chairman, on behalf of the Council, welcomed Dr. J. A. Macdonald after his recent visit to South Africa on behalf of the Association, and drew attention to resolutions by South African Branches expressing appreciation of Dr. Macdonald's work and personality. Dr. Macdonald, at the Chairman's invitation, then gave the Council some account of his travels (a report of this appears in the *SUPPLEMENT* at page 70). The Council placed on record its deep appreciation of the great service rendered to the Association by Dr. Macdonald during his tour of the South African Branches as the Council's representative.

The Question of Federation.

The Council approved for publication the report to Divisions and Representative Body (since published in the *SUPPLEMENT* of March 5th, 1921) upon the steps to be taken whereby the British Medical Association may become in part a federation. The Council resolved to convene an extraordinary general meeting of the Association, to be held at Newcastle on July 19th, 1921, for adoption of the amended articles and by laws enabling the Association to become in part a federation. Should the amended articles and by laws be adopted on July 19th, a further extraordinary general meeting will be held at 429, Strand, London, on August 3rd, 1921, to confirm the adoption. The Council decided also that a conference on this subject should be held at the Head Office on July 5th,

at 10 a.m., and invitations are being sent to the Oversea Branches, the Federal Committees, and the Joint Organization Committee for Ireland. This conference, after consideration of the report and recommendations published in last week's *SUPPLEMENT* will (by instruction of the Council) report direct to the Annual Representative Meeting, with particular reference to the views expressed by the Oversea and Irish representatives.

Professional Secrecy.

Arising out of a recommendation of the Central Ethical Committee the Council expressed the following opinion:

1. That when a medical practitioner refuses to divulge information which he has obtained in the exercise of his professional duties in such circumstances as the following:

- (a) In a court of law when the court has ruled that the information so obtained must be disclosed;
- (b) Where it is already provided by Act of Parliament that he must do so, for instance, as in notification of certain diseases,

such action must be taken entirely on his own responsibility, and the Association could not be expected to support him or protect him from consequences he may incur in so doing.

2. That if attempts be made to add additional exceptions to the general rule of the profession as regards professional secrecy, the Association recognizes that it will be necessary, after due consideration (i) to resist by all lawful means any such encroachment, and (ii) where such encroachment is attempted, to accord support by any means in the power of the Association to any individual practitioner who may be assailed through such new encroachment.

Municipal Hospitals and Clinics.

The Ministry of Health Committee, in its report to the Council, submitted a number of recommendations as to the policy of the Association on the question of municipal hospitals and clinics. It was decided to call a joint meeting of the Medico Political, Public Health, Hospitals, and Ministry of Health Committees, to consider the whole question of municipal hospitals and clinics. The drawing up of an agenda for this meeting was placed in the hands of the four chairmen concerned, who were further empowered to invite to the conference representative medical officers of health or others particularly interested in the setting up or administration of municipal hospitals or clinics.

On the subject of Poor Law hospitals and civil needs a series of proposals put forward by the Hospitals Committee was approved for recommendation to the Representative Body, together with a number of the resolutions passed by the Conference of Representatives of Medical Staffs of Voluntary Hospitals held on December 21st, 1920, and reported in the *SUPPLEMENT* of January 1st, 1921.

The Collective Opinion of the Profession.

The report of the Special Committee appointed to consider the formation of a Central Medical Representative Committee was received and discussed, with particular reference to the memorandum on this subject published in the *SUPPLEMENT* of February 19th, 1921. The Chairman undertook that the Committee would take into consideration the series of questions formulated by Dr. Fothergill, and since embodied in a letter by him printed in the

JOURNAL of March 5th. The Special Committee considering this subject now consists of Dr. Bolam (chairman), Dr. Garstang, Dr. Haslip, Dr. Brackenbury, Sir Jenner Verrall, and Dr. E. J. Macleann. The Chairman stated that the Certifying Factory Surgeons' Association and the Peer Law Medical Officers' Association of England and Wales had already accepted the invitation to co-operate with the British Medical Association in forming such a representative medical committee as the Minister of Health had asked for. (Since then the Society of Medical Officers of Health has also accepted.) The Chairman of the Scottish Committee stated that his committee was of opinion that there should be a Scottish representative on the English Central Committee when set up, and an English representative on the analogous Scottish Committee. This and other points Dr. Bolam undertook to bring to the notice of the Special Committee.

Medico-Political.

The report of the Medico-Political Committee included reference to medical certificates of inability to attend school, fees for medical practitioners called in on the advice of midwives, notification of infectious diseases, fees and travelling allowances for medical witnesses, the Tasmanian Medical Act, and the organization of the Post Office medical officers. Arising out of this Committee's report the Council resolved that the British Medical Association should endeavour to obtain the best terms and conditions for medically qualified laboratory and research workers and professors and teachers, so far as possible in co-operation with the Association of University Teachers. With regard to medical attendance on miners' and other workers' families, it was resolved that free choice of doctor by patient and of patient by doctor should be a recognized principle in all forms of contract practice. It was agreed that the British Medical Association should co-operate with the Association of Certifying Factory Surgeons in an endeavour to obtain increased fees for these practitioners. As recorded in the SUPPLEMENT, the position with regard to the draft Regulations under the Dangerous Drugs Act, 1920, was laid before the Council by the Chairman of the Medico-Political Committee and Dr. J. W. Bone. The Council was informed of the modifications which the Home Office was prepared to grant, but declined to give any opinion as to the practicability of the modified Regulations until the new draft had been seen.

Public Health.

The Public Health Committee was instructed to prepare and submit to a future meeting of the Council a draft Parliamentary Bill providing security of tenure for medical officers of health. On the recommendation of the Committee the Council expressed its approval of a resolution passed in July, 1920, by the National Veterinary Medical Association of Great Britain and Ireland, deprecating the use of tuberculin by persons other than members of the medical and veterinary professions, and calling for immediate steps to control the standardization of tuberculin used in the diagnosis of tuberculosis in cattle.

Emergency Medical Organization.

The report of the Naval and Military Committee introduced to the Council a scheme, drawn up in outline by the Territorial Force Subcommittee, for the expansion of the Army Medical Service in the event of a national emergency. The Council resolved to remit the scheme for consideration and report by an *ad hoc* committee consisting of those members of the late Central Medical War Committee who are members of the Council, together with four representatives of the Naval and Military Committee.

DR. MACDONALD'S MISSION TO SOUTH AFRICA.

At the meeting of the Council of the British Medical Association on February 26th Dr. Macdonald gave an account of the visit he paid last autumn, at the request of the Council, to the South African Branches. A proposal to establish a South African Medical Association has recently been mooted, and Dr. Macdonald's first objective was the Medical Congress in Durban, Natal, where it was anticipated that this proposal would be discussed. Dr. Macdonald, who was cordially received by the Council, began the account of his visit by stating that he left Southampton on September 11th, 1920, by the *Walmer Castle*, and after an uneventful voyage reached Capetown, where the boat stopped for

a day. There he had the advantage of talking with Dr. Jasper Anderson and Dr. Darley-Hartley. After leaving Capetown, stops were made at Port Elizabeth and East London, but at neither place did he go ashore, as the landing facilities at both were bad—by tender at the former, and by basket to the tender at the latter. Medical men journeying to the congress at Durban came aboard at both places.

At Durban, which was reached on October 2nd, he was met by the president of the Natal Coastal Branch of the Association, Dr. Campbell, whose guest he was during his ten days' stay in Durban. The Congress, of which Dr. Campbell was president, was an unqualified success, especially so when it was realized that in the whole of South Africa there are only some 600 to 700 members of the Association, separated by hundreds of miles; over 100 attended the Congress, the largest number that had attended any medical congress ever held in South Africa.

The Congress was run on the same lines as the Annual Meeting at home, with the usual papers, discussions, exhibitions, and entertainments, the latter displaying the lavish and whole-hearted hospitality characteristic of colonial life. On the scientific side the Congress was, he thought, a distinct success, the papers, judging from those he heard, being excellent; the discussions were keen and critical, with a more independent and self-reliant tone than was often heard at home; this characteristic had been notable also at the meetings he had attended during the visit he had paid to Australia and New Zealand in 1914 on behalf of the Association. The exhibition of instruments, drugs, etc., was good, and must have been very useful to practitioners coming from outlying places who had little chance of seeing modern developments in appliances, instruments, and so on.

So far as he was concerned, however, the most interesting aspect of the Congress was the medico-political. The constitution of the Congress was curious in that while it was under the aegis and management of the British Medical Association any medical practitioner could on payment of one guinea attend the meetings, take part in the discussions, and vote on any matter not specially connected with Association work. Many points were raised at the meeting, but the main interest centred in a proposal which had been made to form a Medical Association of South Africa; while the movers in the matter wished to drop the term "British," they expressed the hope that their association would be affiliated or federated to the British Medical Association. The movement originated in the Witwatersrand Branch, and the main reasons assigned for making the proposal were that the new association would not be hampered by the constitution of the British Medical Association, and that an association with the name Medical Association of South Africa would attract men who would not join an association bearing the name "British." A keen discussion took place, during which it appeared that the movers in the scheme proposed to form the new association into a trade union and register it as such. It seemed that it was in this matter that they considered they would be hampered by the constitution of the British Medical Association, and that they were of opinion that the British Medical Association could not undertake collective bargaining. The opinion of their own legal advisers on this point, together with the letters of the Medical Secretary on the subject, proved the latter opinion to be wrong. Dr. Macdonald said that he had been asked to take part in the discussion, but declined on the ground that the matter was one of internal politics in which the central authorities of the British Medical Association had no desire to force the hands of members in South Africa. He had, however, expressed his willingness to give any information he could as to the powers of the British Medical Association or restrictions imposed by its constitution. The discussion on the question whether a separate medical trade union for South Africa should be formed ended by the adoption of a resolution postponing the question until the next Congress, to be held at Capetown this year, and directing that in the meantime the British Medical Association Branches should be consulted and a plebiscite taken.

He had a most kind and flattering reception from the Congress, and every one seemed to vie the one with the other in their determination to make his visit a pleasant one; in this he had no hesitation in saying they had succeeded.

He gathered that there was considerable slackness in organization, and practically no rules concerning ethical procedure, owing probably to the effect of the war. He advised that instead of the Branches acting independently the position of the South African Committee should be strengthened with a view to its being used to settle disputes and conduct negotiations. He recommended also the formation of Divisions in the very large Branches; the appointment of a travelling secretary who would visit the outlying districts from which men had difficulty in attending any congress; the appointment of a correspondent or correspondents to keep alive the intercourse between the Central Office and the South African Branches. He had promised also to try and induce the Central Council to send out a delegate periodically to South Africa on such a mission as his.

From Durban he proceeded to Pietermaritzburg, through some magnificent scenery, one of the finest views he had ever seen being the Valley of a Thousand Kopjes. At Pietermaritzburg, where he was a guest of Dr. and Mrs. Campbell Watt, who made his stay very happy by their kindness, he had an equally hospitable reception. He attended a dinner given by the Administrator of Natal at which all the doctors of the locality were invited to meet him. A well-attended meeting of the profession was held, at which there was an interesting discussion upon the question of the proposed new association. Here again everyone seemed to lay themselves out to make his stay pleasant, and he might at once say that this was true of every place he stopped at.

The next stage of his journey was to Johannesburg. On the way he stayed for a day at Ladysmith, whence he took a car to visit the battlefields. While in Ladysmith he was able to meet all the medical practitioners there; he then went on through Elandslaagte, Majuba, Sand Spruit, among other places, to Johannesburg—a most interesting journey.

Dr. R. Mackenzie, C.M.G., President of the Witwatersrand Branch, with Mrs. Mackenzie, made his stay at Johannesburg like being at home. He had expected that the meeting here would be large, and was not disappointed, something like eighty practitioners being present. When the question of the proposal for a new association came up for discussion he was asked to make a statement from the British Medical Association point of view; this he did, and had expected a keen discussion. In this expectation, however, he was disappointed, the discussion being practically confined to a speech by Dr. Napier in favour of the new association. He (Dr. Macdonald) had no difficulty in correcting the inaccuracies contained in this speech, and the discussion then ended. He understood that at a subsequent meeting of the South African Medical Association only seven practitioners were present. While at Johannesburg he paid a visit, under the guidance of Dr. Watkins-Pitchford and Sir Spencer Lister, to the South African Institute, which is devoted to medical research. The system of investigating and recording the incidence and progress of pulmonary silicosis among workers in the Rand mines was fully explained to him, as were the mode of preparation and results of the vaccine which had been used with success in the treatment of pneumonia complicated by influenza.

From Johannesburg he went to Pretoria, where there was a big meeting of the profession, at which some Dutch practitioners were present; it was held under the chairmanship of Dr. Gairdner, President of the Branch.

While at Johannesburg he had visited the gold mines, and at Pretoria one of the medical men drove him to the Premier Diamond Mine, where the Cullinan diamond was found. It was a curious mine, being merely a big hole in the ground, out of which some 93 million tons of gravel and clay had been excavated. He arrived just at the midday blasting, when in the course of two or three minutes there were some 2,500 explosions. During his stay in Pretoria he had an interview with General Smuts, the Premier, having received an introduction through the kindness of Dr. Peter Macdonald of York.

On the way back to Johannesburg he attended a meeting at Bloemfontein, where he met with the only rain of any consequence which fell during his visit to South Africa. The meeting there was not so well attended as others, owing probably to the short notice and the absence of the President, Dr. Manning. The discussion on the new association, however, was very keen, and there

appeared to be more support for the idea than at any place he visited.

The journey to East London took him through the veldt, which consisted of hundreds of miles of sandy plains—very poor ground and very poor cattle. He was told, however, that had he been a fortnight later he would have found the district covered with grass and flowers. East London, where he stayed with Dr. and Mrs. Bruce-Bays, was a charming seaside place. There was a good meeting of the local medical profession, at which very little sympathy was shown for a South African medical trade union.

Journeying from East London to Grahamstown he had his first experience of travelling by car over the veldt, and though the road was mostly such as an Englishman would scarcely trust his car on, the first eighty miles of the distance, to Breakfastlei, were covered at some twenty miles an hour. This journey, which was through Kaffirland proper, was very interesting, affording many varied glimpses of Kaffir life. At Breakfastlei he was met by two practitioners from Grahamstown, who took him the rest of the journey to that town through some wonderful scenery. Grahamstown, where he was entertained by Dr. Dru Drury, appeared to be the most English town of all those he visited in South Africa. It was a great educational centre and a cathedral city. The meeting of the profession there showed very little sympathy with the idea of a new association. He went with Dr. Dru Drury and Dr. Griffiths from there through fine scenery to Port Elizabeth, and was present at an excellent meeting, which was attended by every practitioner in Port Elizabeth. On his advice it was decided to form a Division at Port Elizabeth, since communication between it and Grahamstown is difficult.

From Port Elizabeth he went on to Capetown by the Garden Route through very beautiful scenery. There was an excellent meeting, at which no sympathy was shown with the idea of a South African medical trade union. During his week's stay in Capetown he enjoyed some very fine drives, and was entertained most hospitably.

From Capetown he went to Kimberley, where the kindness of the profession made his stay very pleasant. Dr. Symons, the President of the Branch, Dr. Lewis Jones, Dr. Wicks, and Mr. Grimmer, assistant manager of the de Beers Mines, doing everything possible for him. The meeting of the medical profession, which was well attended, showed very little sympathy with the idea of a new association. From Kimberley he travelled north into Rhodesia and reached Bulawayo, where Drs. Eaton and Forrester, the President and Secretary of the Rhodesian Branch, looked after his comfort very kindly, and he had the opportunity of meeting most of the doctors of the district. He visited Rhodes's grave on the Matoppos, where also was the grave of Dr. Jameson and the memorial to Major Alan Wilson and the men who died at Shangani. From Bulawayo he went on to the Victoria Falls, a wonderful place, where he spent a few days. During a trip of some ten miles by motor boat on the Zambesi he saw five hippopotamuses and about a dozen crocodiles. Returning from Victoria Falls to Bulawayo, he went on to Salisbury, where Dr. and Mrs. Fleming were particularly kind to him, and the Deputy Administrator of Southern Rhodesia put a car at his disposal, and showed him great kindness generally. The meeting here was one of the best, considering the small number of medical men in the district. Some travelled about one hundred miles by car to attend the meeting.

For himself personally, the tragedy of the trip was that he had been disappointed in his hope of traversing the whole of the Cape to Cairo route by land, going through Tanganyika, Nairobi, Entebbe, to the Nile, and so to Khartoum and Cairo. Difficulties were raised about the journey, and he read in the newspapers that objections were made to a British subject penetrating the Belgian Congo at that time. He had therefore reluctantly abandoned the project, only to receive on his return home a letter from Dr. C. A. Wiggins of Entebbe, stating that the profession there was very disappointed, having made arrangements to convey him from Entebbe to the Nile, arrangements of which he did not know until he received Dr. Wiggins's letter. From Capetown he came home by the *Kentworth Castle*.

The advice he had given as to the organization of the profession, during his visits to the various centres, had been

mainly on the lines of strengthening the position of the South African Committee, and making use of it for dealing with disputes, etc.—the establishment on both sides of more regular correspondence between the Central Office and South Africa, and the bringing into existence thereof of a set of ethical rules.

He was everywhere shown the greatest kindness, and the hope was expressed repeatedly that he would persuade the Council to arrange more such periodical visits. He felt that such a course was desirable, especially when it was realized that in two years the universities in South Africa would be beginning to confer their own degrees; students would then no longer have to come home for a degree or diploma, and the risk of the profession in South Africa becoming estranged from the profession at home would thereby be increased.

The CHAIRMAN called the attention of the Council to two communications received from South African Branches—the one from the Witwatersrand Branch, transmitting a resolution adopted on November 25th, 1920, thanking the British Medical Association in England for sending a man of Dr. Macdonald's outstanding ability, tact, and courtesy to visit the Branch; the other was from the Eastern Province Branch, enclosing a copy of two resolutions adopted on November 29th. The first thanked the Central Council for giving the Branch the advantage of meeting Dr. Macdonald and hearing his explanation of the relation of Overseas Branches to the parent Association; the second stated that the Branch could see no advantage in forming a Medical Association of South Africa, and was resolved in every way to maintain and strengthen the British Medical Association.

On the motion of Sir JENNER VERRALL, seconded by Dr. T. W. H. GARSTANG, Chairman of Representative Meetings, the Council unanimously adopted a resolution placing on record "its deep appreciation of the great service rendered to the Association by Dr. Macdonald in his recent visit to the South African Branches as the Council's representative."

British Medical Association.

CURRENT NOTES.

Work of the Medico-Political Committee.

At the last meeting of the Medico-Political Committee a number of important matters were under discussion: (1) The question of payment for certificates for children who are unable to attend school was considered, and it was decided to recommend the Council to inform all local education authorities that, in the opinion of the Representative Body, such certificates should be paid for by the authority requiring them and that a form of certificate should be provided for the purpose. The Council has approved the recommendation, and the necessary action is being taken. (2) The question of motor car taxation was also considered, and it was decided, with the approval of the Council, to back up the effort of the Automobile Association and Motor Union to obtain the substitution of a flat rate tax on petrol for the present £1 per horse-power tax. (3) At its September meeting the Committee decided to ask the Civil Service Commissioners to raise to one guinea the fee now paid in respect of the examination of candidates for the Civil Service. The Civil Service Commissioners have refused to accede to the request, but the Committee is pressing them to reconsider the decision. (4) As a result of action taken at the September meeting, the Board of Customs and Excise has informed the Association that pensions officers who send applicants for pensions for blindness to obtain certificates of blindness from honorary officers of voluntary hospitals are not acting in accordance with the spirit of the instructions issued to them under the Act. (5) The Council has approved a recommendation by the Committee that the Association should endeavour to obtain the best possible terms and conditions for medically qualified laboratory and research workers and professors and teachers, in co-operation with the Association of University Teachers, and a subcommittee is now considering the matter. (6) Further consideration was given to

the fee for notification of infectious diseases, and it was decided to seek the assistance of the Committee of Medical Members of Parliament with a view to the early restoration of the pre-war fee. (7) The Council has approved the Committee's recommendation that the British Medical Association should co-operate with the Association of Certifying Factory Surgeons with a view to obtaining an increase in their fees. (8) The new rates for telephone service were considered, and the Committee, while regretting the increase, was of opinion that, assuming an increase to be necessary, this will not weigh more heavily on medical men than on other classes of telephone subscribers; the Committee, therefore, did not consider that there were sufficient grounds for making a special complaint.

Fees for Practitioners called in by Midwives (Scotland).

Some time ago the Scottish Committee, at the request of the Scottish Board of Health, submitted a revised scale of fees for practitioners called in by midwives. The scale proposed that (a) a flat rate of £2 2s. be paid for all emergencies arising during or immediately after parturition and should include responsibility for attendance during ten days after confinement; (b) £1 1s. for anaesthetist's fee; (c) £2 2s. for abortion or miscarriage, and (d) 5s. for a single day visit and 10s. 6d. for a night visit. At a conference between the Board and the Chairman's Subcommittee, held on February 25th, the Board intimated that under the Midwives (Scotland) Act, 1915, it was precluded from paying an inclusive fee to cover more than one subsequent visit, and it asked the Committee to reconsider the scale in the light of that, and to submit proposals on the lines of the English scale but including only one subsequent visit.

The Scottish Committee, at a meeting on March 4th, reconsidered the matter, and, having in view the prevailing fees charged for midwifery in private practice, and the decision of the Representative Body that a fee of £2 2s. is not sufficient in cases where operative interference is required, the Committee decided to submit the following scale to the Board, namely:

	£	s.	d.
(1) Fee for all attendances of a doctor during parturition (that is, from commencement of labour until the child is born), whether operative assistance or not is involved, including attendance during the third stage and including one subsequent visit	2	2	0
(2) Fee for attendance of a second doctor to give an anaesthetic	1	1	0
(3) Fee for suturing the perineum, for the removal of adherent or retained placenta, for exploration of the uterus, for the treatment of post-partum haemorrhage, or for any operative emergency arising directly from parturition, including one subsequent necessary visit	1	1	0
(4) Fee for attendance at, or in connexion with, an abortion or miscarriage, including one subsequent necessary visit	2	2	0
(5) Fee for visits to mother or child not included under (1) to (4):			
Day (9 a.m. to 8 p.m.)	0	5	0
Night (8 p.m. to 9 a.m.)	0	10	0
No fee to be paid for subsequent visits during the first ten days after parturition in a case where the doctor has already attended and been paid under (1), (3), and (4).			
(6) The usual mileage fee of the district to be paid for all attendances.			

It was agreed to suggest to the Board that practitioners called in in an emergency should give an honourable undertaking to give all necessary visits during the first ten days without additional charge.

Association Notices.

ELECTION OF COUNCIL OF ASSOCIATION, 1921-22.

A LIST of the Groups of Branches in the United Kingdom for election of twenty-four Members of the Council, 1921-22, and **Nomination Form**, are printed below. The **Nominations** must be in the hands of the Medical Secretary by May 16th.

The result of the election for Members of Council by the Groups of the Oversea Branches was published in the SUPPLEMENT of February 19th, 1921.

GROUPS OF HOME BRANCHES FOR ELECTION OF TWENTY-FOUR MEMBERS OF THE COUNCIL, 1921-22.

(Each Group elects One Member of Council unless
otherwise stated.)

BRANCHES IN GROUP (A)— North of England North Lancashire and South Westmorland	BRANCHES IN GROUP (J)— Dorset and West Hants South-Western Wiltshire
BRANCHES IN GROUP (B)— Yorkshire	BRANCHES IN GROUP (K)— Oxford and Reading Southern
BRANCHES IN GROUP (C)— Lancashire and Cheshire (Two to be elected)	BRANCHES IN GROUP (L)— Kent Surrey Sussex
BRANCHES IN GROUP (D)— East York and North Lincoln Midland	BRANCHES IN GROUP (M)— Aberdeen Dundee Northern Counties Perth
BRANCHES IN GROUP (E)— Cambridge and Huntingdon Essex Norfolk South Midland Suffolk	BRANCHES IN GROUP (N)— Edinburgh Fife
BRANCHES IN GROUP (F)— Birmingham Staffordshire	BRANCHES IN GROUP (O)— Glasgow and West of Scotland (Four City Divisions)
BRANCHES IN GROUP (G)— North Wales Shropshire and Mid Wales South Wales and Monmouth- shire	BRANCHES IN GROUP (P)— Border Counties Glasgow and West of Scotland (Five County Divisions) Stirling
BRANCHES IN GROUP (H)— Metropolitan Counties (Four to be elected)	BRANCHES IN GROUP (Q)— Connought South-Eastern of Ireland
BRANCHES IN GROUP (I)— Bath and Bristol Gloucestershire West Somerset Worcestershire and Here- fordshire	BRANCHES IN GROUP (R)— Leinster
	BRANCHES IN GROUP (S)— Munster
	BRANCHES IN GROUP (T)— Ulster

FORM FOR NOMINATION

BY A DIVISION, OR BY THREE MEMBERS OF A BRANCH, IN
THE GROUP, OF A CANDIDATE FOR ELECTION AS ONE OF
THE TWENTY-FOUR MEMBERS OF THE COUNCIL, 1921-22,
TO BE ELECTED BY THE GROUPED HOME BRANCHES.

* By instruction of the Division I (* or We,
the undersigned Members of the Branch) hereby
nominate

.....
of

as a Candidate for Election by the Branches in Group
.....† as a Member of the Council of the
Association.

.....Honorary Secretary.*
.....Division.*

(.....Member.*
.....Member.*
.....Member.*)

I hereby declare my willingness to serve, if elected, as a
Member of the Council for the year 1921-22.

Candidate's Signature.....

N.B. — The Nominations must be in the hands of
the Medical Secretary, 429, Strand, London, W.C.2., by
May 16th. The above form may be used, or, if pre-
ferred, a separate form will be sent on application to the
Medical Secretary.

* Please omit words not required. In the case of a nomination by
members, the nomination, to be valid, must be signed by at least
three members.

† The Group should be indicated by filling in the index letter (as
above).

ELECTION OF REPRESENTATIVE BODY OF ASSOCIATION, 1921-22.

Constituencies in Representative Body.

THE Council has finally grouped the *Home Divisions*
for election of the Representative Body, 1921-22, in the
same manner as for 1920-21, except that the Caithness
and Sutherland Division of the Northern Counties of
Scotland Branch, and the Rotherham and Sheffield

Divisions of the Yorkshire Branch, have been made
independent Constituencies.

As intimated to all the *Oversca Bodies*, the Council
has made each Oversea Division and Division-Branch an
independent Constituency.

Election of Representatives and Deputy-Representatives.

THE REPRESENTATIVES AND DEPUTY-REPRESENTATIVES
in the Representative Body must be elected not later than
June 17th, and their names notified to the Medical Secretary
not later than June 24th. The Annual Representative
Meeting at Newcastle begins on July 15th.

Special attention is drawn to the fact that the election
of Representative(s) and Deputy-Representative(s) may,
at the discretion of the Constituency, be carried out by
General Meeting of the Constituency, or by postal vote.

MOTIONS FOR ANNUAL REPRESENTATIVE MEETING, NEWCASTLE, JULY, 1921.

NOTICES OF MOTION by Divisions, Constituencies, or
Branches, for the consideration of the Annual Repre-
sentative Meeting of the Association, commencing Friday,
July 15th, 1921, proposing to make any addition to, or any
amendment, alteration, or repeal of, any Article or By-law,
or to make any new Article or By-law, or proposing
material alteration of the policy of the Association in
matters relating to the honour and interests of the pro-
fession or of the Association, must be published in the
BRITISH MEDICAL JOURNAL SUPPLEMENT not later than
May 14th, and for this purpose should be received by
the Medical Secretary not later than April 30th.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A LIST of periodical publications, official reports, and Blue
Books in the Library of the British Medical Association
available for issue to members on loan has been printed, and
copies can be obtained free on application to the Librarian
at the house of the Association, 429, Strand, W.C. The
regulations governing the loan of these publications are
stated in the introduction to the list. The Library is open
for consultation from 10 a.m. till 6.30 p.m. (on Saturdays
10 a.m. till 2 p.m.).

BRANCH AND DIVISION MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.—
A meeting of the Division will be held at 8.30 p.m. on Wednes-
day, March 16th, at 11, Chandos Street. Agenda: Election of
two Representatives of the Division on the Branch Council
any nominations for Representatives should reach the Honorary
Secretaries by first post, March 15th). Address by Dr. T.
Watts Eden, F.R.C.P., on "Some notes on the treatment of
private patients in hospitals in the U.S.A. and Canada."

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—
A meeting of members and non-members will be held on
Tuesday, March 15th, at 8.30 p.m., at St. Andrew's Parish Hall,
High Road, Willesden Green, N.W. (1) Report on conference
with Willesden District Council, etc. (see BRITISH MEDICAL
JOURNAL SUPPLEMENT, March 5th, 1921). (2) Consider forma-
tion of "Practitioners' Mutual Help Scheme" on lines of
Sheffield Division. (3) Clinical meetings and medical club.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—A meeting
of the Branch will be held at the Feathers Hotel, Ledbury, on
Thursday, April 7th, at 3.15 p.m., when a British Medical Association
lecture will be given by Mr. P. Daniel, F.R.C.S., Sur-
geon to Charing Cross Hospital, on "Differential diagnosis of
acute abdominal conditions from a clinical standpoint." A dis-
cussion will follow. The Branch Council will meet at 3 p.m.

Meetings of Branches and Divisions.

JOINT MEETING OF NOTTINGHAM DIVISION AND NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A JOINT meeting of the Nottingham Division of the British
Medical Association and the Nottingham Medico-Chirurgical
Society was held on March 2nd, with Dr. J. F. BLURTON, Presi-
dent of the Society, in the chair. THE MEDICAL SECRETARY,
by invitation of the two societies, addressed the meeting on
"Some of the difficulties of a medical organizer." He detailed
a considerable number of obstacles that he had met during
the thirty years he had been interested in medical organiza-
tion. The chief of these was the fact that nobody liked to
be organized, least of all the medical man, for it meant some
sacrifice of individuality. But the profession had for the

In twenty years been going through a process of intensive education, and was finding out that if it wanted to maintain its influence in public affairs and to preserve its status it must be organized for those purposes. He dealt with the atmosphere of suspicion of leaders which was a marked feature of all organizations; it was due not to any special defect of human nature. The average man did not understand the State government; he did not realize that in selecting a man to represent him he necessarily must repose trust in him. On the contrary, he was inclined to resent action by his representatives because he did not, and could not, know all the facts which had influenced his representatives. This suspicion led to conservative men declining to have anything to do with medical politics, and thereby the profession was deprived of the services of some of its best intellects. Dr. Cox also dwelt on the difficulty of reconciling the various interests inside the profession, and pointed out that no body other than the British Medical Association was capable of doing this, because no other body comprised and catered for all sections as the Association did. He said that up to the present time the consultant physicians, with a few brilliant exceptions, but that economic and other factors were forcing them to see that they also must have representation on which must be able to place the force of the whole of the profession at the back of any section which might be at any particular time. The entry of the hospital physicians and surgeons and medical teachers into medical politics would be a great gain to all.

Dr. Cox urged members to take a proper pride in the Association, that, if properly developed, would make the Association a much greater force than it now was. If doctors could be induced to take the long view, both backwards and forwards, they would perceive that the Association had done great work for every section of the profession, was now more thoroughly equipped for that work than ever it had been, and that its future possibilities were unbounded. He was not at all pessimistic as to the future of medical organization. The difficulties he had alluded to in his address were mainly due to the fact that the medical profession had only recently begun to realize the necessity for organization, as, up to twenty years ago, doctors had merely had to deal as individuals with individuals, and did not need an organization for that purpose. The position was changed nowadays, when all kinds of doctors were continually dealing with organized bodies of lay people, that the difficulties of a medical organizer were bound to get less as the necessity for, and the good results obtained from, organization became more apparent.

After several questions had been asked and answered, Dr. HERRON proposed and Dr. J. H. COX seconded a vote of thanks to Dr. Alfred Cox, which was carried very heartily.

LANCASHIRE AND CHESHIRE BRANCH: BURY DIVISION.

A MEETING of the Bury Division was held on February 2nd to consider the Consultative Council's interim report. Dr. TURNBULL was in the chair. The discussion, in which all took part, was introduced by Dr. I. W. JOHNSON. The advantages were felt to be: (1) Work would be in the hands of the general practitioner. (2) Every general practitioner would have the right to attend his own patients in an institution and have the advantages of institutional treatment, with the right to demand specialist treatment for such cases as needed it. The disadvantages were felt to be (1) the great cost, (2) opposition by present whole-time and part time men adversely affected. A resolution approving the general principles of the scheme was unanimously adopted. A further resolution was passed appointing the Executive of the Division an Advisory Committee provisionally with power to co-opt members to safeguard the interests of the profession in any developments of the subject occurring within the area of the Division.

A MEETING of the Bury Division was held on February 24th, with Dr. TURNBULL in the chair. The HONORARY SECRETARY read the correspondence relating to the Dangerous Drugs Regulations, including the latest information available in the Assistant Medical Secretary's letter of February 21st. A general discussion ensued. On the motion of Dr. COOK, seconded by Dr. YOUNG, it was unanimously resolved:

The Bury Division of the British Medical Association, having read and discussed the proposed Regulations for the sale of dangerous drugs, emphatically protests against the application of these; or any similar regulations, to registered medical practitioners.

The Secretary was instructed to forward a copy of the resolution to the Home Office, the Ministry of Health, the British Medical Association, and the M.P. for Bury. Arrangements were also made with local secretaries and others to forward a copy to M.P.'s of other parliamentary divisions within the area of the Division, and the Secretary undertook to furnish copies of the resolution for this purpose to Drs. Lawrie, J. P. Stuart, and C. Crawshaw. The action of the Association in dealing with the Dangerous Drugs Regulations was criticized on the ground that, instead of devoting its time to getting details amended, the Council should make it plain that what the medical profession required was to be exempt and entirely outside the scope of any such regulations. Dr. NUTTALL proposed the following resolution, which was seconded by Dr. YOUNG, and unanimously carried:

That the Bury Division of the British Medical Association is of the opinion that the concessions mentioned in the Assistant Medical Secretary's letter of February 21st are utterly inadequate and do

not cover the objections to the draft Regulations, and requests the British Medical Association to call upon the Home Office to withdraw these draft Regulations unconditionally, in so far as they relate to registered medical practitioners.

A copy of the resolution was directed to be sent to the Medical Secretary of the British Medical Association.

Several members spoke on the subject of the new pink monthly certificates for insured persons, and described the difficulties they had experienced in obtaining from their respective Insurance Committees sufficient copies of them for their requirements. On Dr. J. HOLMES's motion it was decided to bring the matter to the notice of the Insurance Acts Committee of the British Medical Association, in order that that Committee might use its influence to get a better supply for insurance practitioners.

MALAYA BRANCH.

At a meeting of the Malaya Branch of the British Medical Association at Kuala Lumpur, Selangor, Federated Malay States, in October, 1920, a paper was read by Dr. A. J. McCLOSKEY, S.M.O. Selangor, on the effect of the control and rationing of rice on beri-beri. He pointed out that control of rice came into force early in July, 1919, and rationing in January, 1920, in Perak, and in February, March, and April, 1920, in different parts of Selangor, and in 1920 he had found a marked reduction of the number of beri-beri cases admitted to hospital. The figures were: for Perak, in 1919, 504 cases of beri-beri treated, in 1920, 57 cases; or in 1919, 2.2 per cent. of the total of all diseases, in 1920 of 0.2 per cent. For Selangor, the corresponding figures were 673 cases in 1919, 173 in 1920, or 4.21 per cent. of all diseases treated, to 0.9 per cent. The rice consumed in Selangor and Negri Sembilan during 1919 and first two months of 1920 was Siam rice; since February, 1920, the rice consumed in Selangor has been all Rangoon and in Negri Sembilan mostly Rangoon. In Perak mostly Rangoon rice was consumed during the whole of 1919 and 1920, and in this State was found the lowest percentage of beri-beri during 1919, verifying the fact as stated by Fraser and Stanton that Siam rice was considerably more potent in its beri-beri-producing power than Rangoon rice. The control and rationing of rice had varied the rice used not only in quantity, but in kind and variety, and the reduced rice ration was supplemented by other articles of diet such as sweet potatoes and wheat flour, and in this way prevented the occurrence of beri-beri. The Siam rice consumed in 1919 was of a broken variety and not highly polished.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.

A MEETING of the City Division was held on March 2nd at the Metropolitan Hospital, Kingsland Road, N., when Dr. CUTHBERT DIXON was in the chair. There was a good attendance. Mr. W. MCADAM ECCLES delivered a comprehensive and helpful lecture on the early diagnosis of acute abdomen, which was greatly appreciated. An animated discussion followed, and the proceedings came to a close with a very hearty and unanimous vote of thanks to Mr. Eccles.

NORFOLK BRANCH: EAST NORFOLK DIVISION.

A MEETING of the East Norfolk Division was held at Norwich on March 1st. It was decided that as all the Poor Law authorities had increased the district medical officers' salaries by 12 to 33½ per cent., no further increase should be asked for at present. Several of the members were of the opinion that the work was decreasing. It was reported that the fee for attendance upon pauper women in confinement was in many cases inadequate. A resolution was passed requesting the guardians to adopt a universal fee of £2.

The following protest was sent to the Home Office:

This Division of the British Medical Association protests against any Regulations which affect medical men being issued without the profession being previously consulted.

INSURANCE.

DISTRICT MEDICAL OFFICERS FOR SCOTLAND.

THE Scottish Board of Health announces that it has appointed the following medical men to be District Medical Officers:

Senior District Medical Officers.—Western District (Headquarters, Glasgow): R. Buchanan, M.B., C.M., D.P.H. South-Eastern District (Headquarters, Edinburgh): A. M. McIntosh, C.M.G., M.B., Ch.B., F.R.C.S.

Junior District Medical Officers.—South-Western District (Headquarters, Glasgow): John Gilmour, M.B., C.M., F.R.C.S., D.P.H. Northern District (Headquarters, Aberdeen): John Jeffrey, M.B., Ch.B., F.R.C.S. Eastern District (Headquarters, Dundee): J. Murray Young, M.B., C.M.

These officers will act as Medical Referees in cases referred to them on questions of incapacity of insured persons for work and as consultants in giving second opinions on questions of diagnosis and treatment. They have also administrative duties in connexion with the Insurance Medical Service and other work of the Scottish Board of Health.

CORRESPONDENCE.

The New System of Medical Records.

SIR,—From reading the correspondence on the new system of medical records it is clear that there are two sides—a majority who view them with more or less disfavour and a minority who take the opposite view. I am inclined to think that the latter consist of those who have small panels and those who have very large ones. These last, no doubt, are fortunate to have dispensers who can relieve them of all the dispensing and book-keeping connected with their private practice, and so give them time to ferret out the record cards.

Speaking as a country practitioner who has to do all his own dispensing, both for private patients and insured patients in rural areas, I regard them as an unmitigated nuisance and from a clinical point of view quite useless. Holding as I do other appointments, I am appalled at the time nowadays which is taken up and wasted in what I term ink splashing.

We are provided with record envelopes often incorrectly addressed, and on the assumption that everybody brings his or her medical card with them, whereas it is the exception for them to do so and not the rule. In country districts it is not uncommon to have twenty or thirty patients with the same surname, and it is hardly to be expected that we can remember everybody's Christian name; and so it, say, out of twenty patients called Pike we enter the details of one of them on the envelope of another Pike in error, we are not provided with spare envelopes to replace the defaced one. What will happen when we take our holidays, and locums who are strange to the district replace us, Heaven only knows. When we visit a patient are we to spend our time finding out his age, occupation, married or single, which is annoying to both doctor and patient?

In the numerous letters that have been written on this subject I have not seen any reference to one most important point from the patient's point of view, and that is that the time taken up in taking out the record envelope from its file and filling up the details diverts the mind of the doctor from concentrating his attention on the diagnosis and treatment of his patient. You cannot have it both ways. One cannot imagine what would happen in a time of a bad influenza epidemic. This winter has been a comparatively healthy one, and even so many of us have to fill in our records after evening consulting hours when we should be resting.

If, however, some form of records is bound to stay, I agree with the letter of Dr. Manson in to-day's SUPPLEMENT that every insurance practitioner should carefully consider the alternative proposals of Dr. T. Wood Locket, as outlined in his letter of February 19th. It is certainly a most excellent and well-thought-out idea.—I am, etc.,

Gillingham, Dorset, March 5th.

R. W. MORGAN, M.D.

DANGEROUS DRUGS REGULATIONS.

We printed last week in the SUPPLEMENT the letter received by the Medical Secretary from Sir Edward Troup, Permanent Under-Secretary of State in the Home Office. The following joint reply was forwarded to the Home Secretary on March 3rd. It was signed by the Medical Secretary of the British Medical Association, the Secretary of the Pharmaceutical Society of Great Britain, the Vice-Chairman of the Scottish Pharmaceutical Federation, the President of the Pharmaceutical Society of Ireland, and the Secretary to the Parliamentary Committee of the Co-operative Congress.

March 3rd, 1921.

SIR,

Your letter of the 25th directed to the signatories of the letter of the 22nd February respecting the Regulations issued under the Dangerous Drugs Act, 1920, was considered to-day at a full meeting of the signatories, which passed the following resolution:

This meeting learns with grave concern the unwillingness of the Home Secretary to appoint an expert committee to advise him before he makes the Regulations under the Dangerous Drugs Act, and resolves to take every step to bring to the notice of Parliament the absolute necessity for the appointment of such a committee.

The meeting appointed a small subcommittee, consisting of the signatories to this letter, and instructed us to bring to your notice the following observations.

It is by no means the intention of any of the bodies which have approached you on this subject to dictate to you the form of the Regulations. On the contrary, we

unreservedly recognize your responsibility for carrying out the objects of the International Opium Convention, and we do not suggest that you should enter into any process of bargaining between the conflicting interests. What we do press for most earnestly is, that in making the Regulations which will govern the dealings of large numbers of people with very important drugs, you will be guided by people who know what the difficulties are, have considered the points of view of the various sections concerned in dealing in these drugs, and more especially have tried to combine these views in such a way as to convince you that no section has been overlooked, and that the public interest will be conserved.

We would most respectfully suggest that you should reconsider this question of the appointment of a committee. We do not ask that the committee shall be a committee representative of the different interests. We ask that it should be composed of persons who have sufficient knowledge of the technical points, including the legal points, to enable them to appreciate the representations of persons representing the various interests involved.

We feel sure that such a process would not lead to any waste of time but rather that it would be a much quicker process than the one suggested in the last paragraph of your letter of the 25th ult. Moreover, it would enable the various bodies concerned to place their views before the committee in the presence of each other and so give the committee which would advise you every opportunity for reconciling as far as possible the different points of view.

We believe, Sir, that you have no conception of the strong resentment which has been caused by the publication of the draft Regulations without previous effective consultation with bodies that are deeply and legitimately interested in dealings with dangerous drugs. We are anxious to assist you in arriving at Regulations which, while meeting the main object for which such Regulations have to be devised—namely, the control of illicit traffic in these drugs—will be as little onerous as possible.

We believe that our suggestion of a committee advising you after having heard what can be said by the bodies concerned will be the best and the quickest way of enabling practical Regulations to be made.

Nabal and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty: Surgeon Captain D. W. Hewitt, C.B., C.M.G., to the *President*, for hospital ship *Panama*. Surgeon Commanders J. W. Craig to the *Orion*, as Squadron Medical Officer, L. Lindop to the *Hawkins*.

ARMY MEDICAL SERVICE.

Colonel Lancelot P. More is placed on half-pay April 1st, 1920 (substituted for notification in the *London Gazette*, January 27th, 1921).

ROYAL ARMY MEDICAL CORPS.

Major T. E. Harty, D.S.O., relinquishes the acting rank of Lieutenant-Colonel.
Major C. Kelly, M.C., is placed on the half-pay list on account of ill health.

Major J. B. Clarke retires on retired pay.
Temporary Major J. H. Spencer to be Captain, January 25th, 1912,
but not to reckon for pay or allowances prior to June 1st, 1921, with
precedence next below R. O. Kelly, and to retain the temporary rank
of Major (substituted for notification in the *London Gazette*, July 23rd,
1922).

To be temporary Captains: E. G. S. Hall, late Captain S.R., with seniority March 3rd, 1918; R. Stephens, late temporary Captain, with seniority October 15th, 1915.

Lieutenant J. F. P. Gallagher resigns his commission.

Major Temporary
the rank of Major.
in: I. Ridge Jones,
Z. A. Green, E. G. M. Gilchrist, W. Kirk, H. H. McClelland, Temporary
honorary Captain M. Bronk, and retains the honorary rank of Captain.
Temporary Lieutenant J. A. B. Sim.

INDIAN MEDICAL SERVICE.

Major J. A. Cruickshank appointed temporarily to the staff of the Bombay Bacteriological Laboratory.
Lieut.-Colonel C. Milne and Brevet Colonel W. H. Ogilvie have been promoted to the rank of Colonel (May 19th and 23th, 1920, respectively).

Major E. H. B. Stanley has been promoted to the rank of Lieut.-Colonel (July 28th, 1929).

Lieut.-Colonel J. Entrican appointed to hold the office of the Inspector-General of Civil Hospitals, Burma, substantively *pro tempore*, with effect from April 21st, 1920, until further orders.

Major H. W. Pierpoint has been posted as Agency Surgeon, Baghelkhand.

Lieut.-Colonel S. Hunt has been appointed Residency Surgeon.

Cooper, W. L. Forsyth, and G. T. Burke.

The Royal Victoria Infirmary, Newcastle-upon-Tyne. (Photograph taken from the Leazes Park.)

EIGHTY-NINTH ANNUAL MEETING of the British Medical Association, NEWCASTLE-UPON-TYNE, 1921.

SOME OF THE TOWN'S INSTITUTIONS.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

A school of medicine has existed in Newcastle since 1832; when the Newcastle-on-Tyne School of Medicine and Surgery was formed by a few local medical men, with the brothers Fife as prime movers. There were at first only nine students, and the lectures were given in a room in Bell's Court, Pilgrim Street. After two years the founders, feeling the need of better accommodation, and emboldened by the success of their first two sessions, rented the Hall of the Worshipful Company of Barber-Surgeons together with Wax and Tallow Chandlers, in the Manors. The Hall itself was destined for the museum, and the space below was partitioned off and fitted up into a lecture room, a chemistry and materia medica room, and a dissecting room.

Down to 1851 the school grew and prospered; then, owing to violent dissensions among the staff, two rival schools were started. That of the majority in 1852 became associated with the University of Durham, and was known as "The Newcastle-on-Tyne College of Medicine in connexion with the University of Durham." Students were now enabled to proceed, first, to a licence in Medicine, and secondly, later, to the degrees of Bachelor and Doctor of Medicine. In the previous year the school had been recognized by the Society of Apothecaries of London and by the Royal College of Surgeons of England. By this time the old building at the Manors had to be demolished to make way for the extension of the North-Eastern Railway. New premises were built in the gardens of Westmorland House, near the Library of the Literary and Philosophical Society; this became known as the Orchard Street School of Medicine.

The minority of the lecturers formed a school entitled "The Newcastle-upon-Tyne College of Medicine and Practical Science," which was housed in the new Barber-Surgeons' Hall, still to be seen at the top of Westmorland Street. After working separately for some six years a reconciliation was brought about, and the two schools amalgamated to their mutual benefit. The incident of the disruption would probably have long been forgotten had the memory not been perpetuated in the humorously satirical ballad entitled, "The Knights of St. John and the Cross, or the Raid o' the Auld Musee," which records

in some fifty stanzas how the "minority" surreptitiously removed some of the best specimens from the stable in which the "majority" had temporarily housed the museum. In 1870 a still closer union was formed with the University, and the College has since been known as "The University of Durham College of Medicine."

Owing to the further exigencies of railway development, Orchard Street had to be vacated in 1889, and the present college in Northumberland Road, a photograph of which is here reproduced (p. 392), was opened.

In 1906 the building was greatly enlarged and improved by the addition of the Heath Wing, which was erected from funds left by Dr. George Yeoman Heath, who was President of the College from 1874 until his death in 1892. During the last twenty years the work of the College has greatly increased, and the number of students has gone up from an average of 200 to no less than 433 at the present time, and of this number seventy are women.

ARMSTRONG COLLEGE.

The subjects of chemistry, physics, and biology are taught at Armstrong College, which, with the College of Medicine, goes to form the "Newcastle Division" of the University of Durham. This institution was founded in 1871 as a science college, but its scope has been greatly extended, and it now includes faculties of arts and of commerce.

The work of the College is conducted in twenty-three teaching departments, of which perhaps pure Science, Mining, and Agriculture are the most important. In association with the latter is the experimental station at Cockle Park, and the practical Forestry Department at Chopwell Woods. As befits a shipbuilding district, the College contains an important department of Naval Architecture, one of the three which exist in the country. The Art Department is well attended, the work being carried on in the King Edward VII School of Art. The Department of Commerce is a comparatively recent addition, but is becoming increasingly important. In 1920 the number of students on the books of the College was 1,174, and many had to be refused admission. Unfortunately, both the University Colleges find themselves in sore need of additional funds, and they are at present appealing to the public for half a million pounds; of this sum about £150,000 has so far been subscribed or promised.

THE ROYAL VICTORIA INFIRMARY.

The Newcastle Infirmary was founded in 1751, being built in the period which saw the inception of so many of our provincial hospitals. When the project was first mooted it was taken up so enthusiastically that, rather than wait for the completion of the new building, a house in Gallowgate was used temporarily. The original infirmary, which was opened for patients in 1753, contained ninety beds and appears to have been a severely plain structure, with no needless ornamentation. With its additions of later years, the building still stands near the Central Railway Station:

Grim Lazzaretto, deserted and still,
The birthplace and cradle of surgical skill!

The accommodation was fully utilized from the beginning, 500 to 600 patients being admitted each year, and there were frequent complaints of overcrowding. The original staff consisted of four physicians and two surgeons; the number of surgeons was increased to four in 1760 and to six in 1920.

In 1803 the building was reconstructed and enlarged to contain 100 beds. During 1801 the in-patients treated

numbered 643 and by 1830 this number had increased to 1,000, so that the extension was not keeping pace with the needs of the district, and overcrowding was still prevalent; accordingly, 22 beds were added by the addition of a third story; the relief of pressure thus obtained was, however, of short duration, and in 1850 a new wing was begun to provide 141 more beds. Three years later epidemics of typhus and cholera broke out in Newcastle and the new wards were brought into use whilst the wing was still in an unfinished state. The in-patients rose to 1,679 annually, but the increase was greatest amongst "casuals"; their number rose to 16,000 in 1870. Fifty more beds were added in 1885, and about this date the constitution was altered in several ways. The Infirmary was made free—that is, letters of recommendation were no longer required for admission; the House Committee and medical staff were amalgamated, and workmen governors were appointed from those works which contributed to the funds.

In the last years of the last century it became obvious that the building was unable to cope with the needs of the district; overcrowding was often acute. Several plans were brought forward for a new building, and finally, in 1896, a public subscription was opened for this purpose to commemorate the Diamond Jubilee of Queen Victoria. Plans were prepared and a site selected after some delay, and with this public subscription, together with two munificent gifts of £100,000 each from the late Mr. John Hall and Lord Armstrong, the present building was erected. The foundation stone was laid in 1900 by H.R.H. the Prince of Wales, and in 1906 the building was formally opened by him when King Edward VII. The hospital is on the pavilion system, with original accommodation for 400 patients. A central corridor traverses the building, which has the Nurses' Home (for 100 nurses) at its upper end and the out-patient department at its lower. Leading off this corridor are ten pavilions, of two stories, making twenty

wards, each a complete unit, with ward, kitchen, scullery, day room, linen room and sister's room. The administrative block is in the centre, and comprises entrance hall, library, board room, general offices and resident staff quarters. The out-patients' department consists of a central waiting hall, around which are consulting and examination rooms.

During the war additions were made, two surgical wards and a large skin department being provided—the accommodation was thus increased to 550 beds. The latest addition is the large Orthopaedic Hospital, which adjoins the Infirmary, and which at present, with huts, contains 500 beds more. This was built mainly by public subscription, but with assistance from grants from the Government, Red Cross Society, and relief funds for the treatment of "soldiers, pensioners, and civilians." It is at present under the charge of the Ministry of Pensions, but at the expiration of the Ministry's lease will revert to the Infirmary.

Again the Infirmary is proving far too small for the needs of the district. In 1919 the number of in-patients treated was 9,551 and 72,429 new out-patients were registered, with an aggregate of 160,151 attendances. The

waiting list, then over 1,300, is still growing, although the beds are being used to their utmost capacity.

Among the other medical institutions in the town are the Children's Hospital, the Lying-in Hospital, the Eye Infirmary, the Throat and Ear Hospital, the Skin Hospital, and the Dispensary.

LITERARY AND PHILOSOPHICAL SOCIETY.

This institution, familiarly known as the "Lit. and Phil.," appeals to a wide range of taste and attainment in matters

intellectual. Lectures by specialists are provided on all sorts of subjects, including some systematic educational courses. Occasionally lectures in French and German are given. But its crowning usefulness and popularity lies in its large library, which has been accumulating since its foundation, and which ranges from recondite volumes in literature and science to the most ephemeral fiction. Members roam at will among the hundreds of well-filled shelves and pick and choose whatever they wish to peruse in the comfortable reading room. The leading magazines and periodicals are also provided, and all may be borrowed under suitable regulations. The Society was founded in 1793, and the present buildings were opened in 1825. But previous to the definite foundation of this Society, there existed a society which may be looked on as a tentative effort towards the goal subsequently reached. The Philosophical Society, which was founded in 1775 and devoted itself to discussions, had but a brief existence. One of its members, Thomas Spence, was much in evidence in his day. He was a schoolmaster who advocated communal property in land, and invented a phonetic system of spelling, of which the following is a specimen:

"It may hile perpleks a karlls redir ov nu karaktirs too disifir the tru sens thereov: tho it shud be eze ennf too no it bi a litil aplekashin and praktis."

A fighting man was Spence, and having violently upbraided Thomas Bewick for not supporting him in a

The University of Durham College of Medicine, Northumberland Road, Newcastle-upon-Tyne.

debate, he received a good cudgelling from the famous engraver. He subsequently removed to London, where he was frequently in conflict with authority.

The idea of founding a medical school in Newcastle first originated with a distinguished member of the "Lit. and Phil.," Dr. Greenhow, who endeavoured to arouse interest in the project by reading a paper before the Society dealing with the matter as early as 1831.

THE HANCOCK MUSEUM.

This museum, owned and maintained by the Natural History Society of Northumberland, Durham and Newcastle-upon-Tyne, is housed in an imposing building finely situated to the north of Barras Bridge, a centre with which the members attending the Annual Meeting will quickly become familiar. Of its contents, more particularly interesting are the Hancock collection of birds; Thomas Bold's Northumbrian insects; the herbarium of N. J. Winch; and collections of fossils from the local coal measures. The ethnological collection is notable not so much for its great extent as the unique interest of many of the objects, some of them brought back by Captain Cook's expeditions, and therefore before the age of faking and wholesale imitation. The Museum also contains a splendid collection of the original drawings and woodcuts of Thomas Bewick, the famous Newcastle engraver.

Those who are interested will find in the Free Library in New Bridge Street, and adjoining the Laing Art Gallery, a unique collection of Bewicksoniana known as the Pease bequest. The site of the house in which the engraver lived and worked is marked by a bust in the wall of Milburn House, adjoining the south side of St. Nicholas's Churchyard.

THE LAING ART GALLERY.

This gallery, in Higham Place, three minutes' walk from the College of Medicine, is a recent addition to the attractions of the city. Due to the munificence of the late Mr. Alexander Laing, it fills a want that had been long

experienced. The building, which is in the Renaissance style, reflects the greatest credit on the architects, but from the outside cannot be adequately appreciated owing to the narrowness of the street. The interior is appropriate to its purpose, and the visitor at once feels himself in the fitting atmosphere for a picture gallery. Already the permanent collection is quite considerable, and excellent examples of most of the leading modern painters are to be found on its walls. To mention a few—

Edward Armitage, Frank Brangwyn, H. P. Briggs, A. E. Brown, George Clausen, H. H. Emerson, Stanhope A. Forbes, G. C. Haite, Chas. Napier Henry, Niel M. Lund, J. F. Lewis, H. H. La

Thangue, George Wetherber, J. W. Waterhouse, Thomas Miles Richardson (senior and junior), Edward Richardson, Sir J. Noel Paton, J. W. Oakes, and A. Wakin Nicol are represented. There are always some pictures on loan from the National Gallery, and from time to time exhibitions of the work of local artists are held.

[The photographs are by Messrs. Jas. Bacon and Sons, Newcastle-upon-Tyne.]

The Hancock Natural History Museum.

The provisional programme, so far as arrangements have already been made, for the Annual Meeting at Newcastle was published in the SUPPLEMENT of March 5th. The list of Officers of Sections was complete save for the Sections of Oto-Rhino-Laryngology and of Radiology and Electro-Therapeutics. The Officers of these

two Sections have now been appointed as follows:

Oto-Rhino-Laryngology.

(Two-day Section.)

President: G. WILLIAM HILL, M.D. Vice-Presidents: JAMES DON, M.D.; R. GORDON BELL, M.D.; DAN MCKENZIE, F.R.C.S. Edin. Honorary Secretaries: LIONEL COLLEDGE, F.R.C.S. (22, Queen Anne Street, London, W.1); W. FRANK WILSON, M.B., B.S. (97, Jesmond Road, Newcastle-upon-Tyne).

Radiology and Electro-Therapeutics.

(Single-day Section.)

President: WILLIAM IRONSIDE BRUCE, M.D. Vice-Presidents: W. HOPE FOWLER, F.R.C.S. Edin.; ROBERT EDWARD HOWELL, M.B., B.S. (23, W.1); THOMAS LOWE BUNTING, M.D. (wcastle-on-Tyne).

British Medical Journal.

SATURDAY, MARCH 12TH, 1921.

A PSYCHIATRIST'S REVIEW.

THE Physician-Superintendents of what is now known as the Royal Edinburgh Mental Hospital have accustomed us to expect that their annual reports shall partake rather of the nature of disquisitions on current psychiatric topics than detailed statistical statements. We propose here to make some comments on three topics, of interest alike to the profession and the public, dealt with by Dr. George Robertson in his report for 1920.

Some five-and-twenty years ago the late Sir Thomas Clouston, then physician-superintendent, induced the managers to build a hospital on a fine site in the outskirts of Edinburgh for the reception of private patients; the success of this hospital—Craig House—has surpassed the highest expectations of those who promoted it. Of the 126 patients admitted last year to Craig House no fewer than 66, or more than half, entered as voluntary patients. The procedure is simple: an application is made to the physician-superintendent in writing, who, if he thinks proper, admits the patient, and a similar application is sent to the Board of Control, which gives its sanction without further formality should the application be clear and unambiguous. The whole amounts to little more than notification. Dr. Robertson asks, "if the majority of patients of the richer classes are prepared to enter a mental hospital voluntarily for early treatment and without certification, and if their financial and other interests are sufficiently safeguarded by a formality which resembles notification," why should not similar facilities be available for the poor? At present the only course open, even in Scotland, to a person afflicted in mind, and not endowed with wealth, is to submit to certification as a lunatic and to be committed under an order granted by a sheriff. It is, Dr. Robertson says, useless in these circumstances to hope for the adoption of early treatment; he thinks that the Act of 1857 should be amended, and that the financial difficulty would be overcome were the Government grant in aid, given to assist in the maintenance of certified parochial patients, also given for voluntary parochial patients. Another but much more expensive plan by which early treatment can be obtained in Scotland is by temporary residence in a nursing home. This plan, it would appear, is approved by the Board of Control, for Dr. John Macpherson, one of the medical commissioners, in his address at the celebration of the centenary of the Dundee Royal Asylum, said: "We are inclined to think that adjunct houses, in which patients afflicted with certain forms of insanity could be received without the strict legal formalities at present recognized, would prove a beneficial modification of our asylums." The managers of the Edinburgh Mental Hospital are in sympathy with this proposal; they have already established two such houses or homes, and hope to open a third this year.

The second topic of general interest discussed in Dr. Robertson's report is the policy of the temperance party in Scotland in seeking to secure total prohibition of the sale of alcoholic beverages when the vote

under the Scottish Temperance Act was taken last year. As will be seen from the table reproduced on p. 401, the percentage of admissions to the Edinburgh Mental Hospital in which alcoholic excess is believed to have been the exciting cause has progressively declined in both sexes since the beginning of this century; alcoholism was less frequently assigned as a cause among women than among men, and the decline among them has been very remarkable. In the seven years before the war alcoholic excess was given as the exciting cause, on the average, in 9.6 per cent. of the cases in women; in the following seven years the average was 2.6; last year the percentage was only 1.0. It is pointed out that the number of cases of insanity alleged to be due to alcoholic excess is little more than a rough means of gauging the amount of excessive drinking in a community. "It only represents a fraction of the evil done to the nation by intemperate habits, just as the number of balls that find their way into the Swilcan Burn would represent a fraction of the bad play over St. Andrews Links." Still Dr. Robertson is not prepared to prescribe total prohibition for all, and in this he undoubtedly shares the opinion of his predecessor, Sir Thomas Clouston. "A simple and direct procedure like prohibition," he says, "may appear to be a very obvious remedy for the evil, but we have been well warned by Herbert Spencer that in a complex organization like civilized society such interference often brings with it consequences which are worse for the social body than the disease it is intended to remove." Owing to this attitude Dr. Robertson is regarded by the temperance party as a source of weakness, in spite of the views he has expressed on the subject of excess. His retort is—if that party had been content to advocate a reduction of licences they would probably have been rewarded with success.

Dr. Robertson, it will be remembered, is Professor of Psychiatry in the University of Edinburgh, and the third topic of general interest treated in this report is psycho-analysis. The theory of repression he regards as the main pillar of psycho-analysis, and that, he holds, leads inevitably to the conception of an unconscious, yet active, mind, for the repressed subject, "though forgotten, is not annihilated. It continues to exist unconsciously, and this not in a passive state, but as an active, though unsuspected, force." Freud's work, he considers, is continuous with that of two great teachers of the Edinburgh school; thus the unconscious mind is but an elaboration of the psychological aspect of Professor Laycock's famous hypothesis of "reflex, automatic, or unconscious cerebration," applied by him to account for the phenomena of delirium, dreams, and somnambulism. The idea of repression was grasped by Sir Thomas Clouston when he wrote in 1880: "The intense and complete outward repression and inhibition of certain physiological cravings required by our morals and our civilization causes, no doubt, a dangerous strain on the brain functions and a reaction in other directions, where there are hereditary neurotic weaknesses." And in another place he said: "The psychological analysis of what female modesty is, by a physiologist, reveals the transformation and apotheosis in the higher regions of the brain of reflex impressions from the reproductive organs into a high moral quality, not only beautiful, but absolutely essential to social life." Professor Robertson then goes on to point out how the theory of conscious and unconscious forms of mental action is in accord with the views enunciated many years ago by Hughlings Jackson, that

the higher nervous arrangements were evolved out of the lower, and kept down or repressed the lower, just as a Government evolved out of a nation controlled as well as directed that nation. In dreams, the conscious level, tired by the day's work, is put out of action during sleep, and the lower unconscious level runs riot in primitive and illogical dreams and nightmares. In insanity the higher or conscious level is usually put out of action to a greater or less degree by obscure poisons, by exhaustion, or by both, and the patient suffers from dreams by day, or at least from delusions and "such stuff as dreams are made of." Professor Robertson, therefore, is grateful to Freud for what he has done to bring the working of the sound and unsound mind into line with and closer to one another. People, Professor Robertson thinks, are furious with Freud because he endeavours to make them realize the kinships of their own highly cultured minds to those of beings of a primitive, coarser, or inferior type, whether these be children, savages or animals. This aspect of the matter is fully discussed in the remarkable book on *Instinct and the Unconscious* by Dr. Rivers, which was reviewed in our columns of February 26th, p. 305. The causes of such "fury" as has been displayed are other.

TRINITROTOLUENE POISONING.

THE modern high explosive trinitrotoluene or trinitrotoluol—commonly called T.N.T.—is a fine crystalline yellow powder sometimes used by the shell filler in the form of fused yellowish-brown lumps. It is obtained by nitrating toluene—a product of coal-tar distillation. Before the war it was generally believed to be much less toxic than trinitrobenzene, which had been manufactured in this country on a small scale for many years. Indeed, until towards the end of 1915 T.N.T. was looked on as an innocuous substance which had never been observed to set up illness. In November, 1915, toxic jaundice was added to the schedule of diseases that have to be notified to the Chief Inspector of Factories by a Home Office Order, but this was because of the toxic jaundice which had occurred in various aeroplane factories from the use of tetrachlorethane (a constituent of the dope or varnish applied to the canvas wings of aeroplanes), the cause of which was first discovered in this country in December, 1914. In the latter part of 1915 a few cases of toxic jaundice due to T.N.T. poisoning were reported, and in 1916 and 1917 a considerable number of cases of undoubted poisoning occurred. The question whether the poisonous effects were due to trinitrotoluene itself or to impurities or admixtures with it was fully considered; the conclusion reached was that T.N.T. alone was the causal factor.

An interesting Report¹ has now been issued by the Medical Research Council on T.N.T. poisoning and the fate of this substance in the animal body. Dr. W. J. O'Donovan gives an account of the clinical symptoms occurring amongst workers in munition factories where T.N.T. and preparations containing it were used. The clinical effects included anaemia, dermatitis, gastritis, and toxic jaundice. The severe types of anaemia were of the aplastic type and no parallelism existed between the occurrence of toxic jaundice and fatal anaemia. The occurrence of dermatitis was of interest since the conclusion to which the work of Professor Benjamin Moore pointed was that the skin was the main channel of absorption. No connexion was established between the occurrence

of dermatitis and the two fatal manifestations of T.N.T. poisoning, toxic jaundice and aplastic anaemia. During the later stages of the war trinitrotoluene was largely mixed with ammonium nitrate for purposes of shell filling, as much as 80 per cent. of the latter being used, and this from its hygroscopic nature appeared to play an important part in the occurrence of dermatitis.

Toxic gastritis is described as of frequent occurrence; its relationship to toxic jaundice is not emphasized, though, from analogy with the tetrachlorethane cases, it seems likely that it would be an important premonitory symptom. Toxic jaundice appeared to occur more frequently in young adults, who when attacked were very prone to die, and in consequence employment in T.N.T. work of persons below the age of 18 was prohibited. The jaundice was associated in its early stages with enlargement of the liver and later with shrinkage, and it is interesting to note that ascites was observed in one case in which considerable shrinkage of the liver was found. A very important observation was the long latent period that might supervene between exposure to T.N.T. and the development of toxic jaundice. Dr. T. M. Legge recorded a case in which the latent period was seven months, and Professor Glynn one in which it was nine months. These observations are at the present time receiving confirmation from the long latent period that may intervene before toxic jaundice follows the administration of preparations of arsenobenzol, which are too often used with complete disregard for their effect on the liver cells. There seems to be no doubt that toxic liver poisons cause damage leading to ultimate necrosis of the liver parenchyma, and that a long latent period may supervene before a toxic jaundice, often of fatal type, occurs.

The animal experiments carried out by Dr. G. A. Wyon did not throw much light on the effects of T.N.T. observed in human beings. After doses relatively very much larger than those to which workers would be exposed, hepatic degeneration was produced in cats, rabbits, rats, and monkeys, but chronic poisoning with small doses did not cause it. In rabbits the administration of large doses of T.N.T. caused blood changes resembling an early stage of aplastic anaemia. The conclusion drawn from the animal experiments was that an unknown second factor probably co-operates with T.N.T. in the production of fatal forms of poisoning in man.

An interesting account of the metabolism and excretion of T.N.T. is given by Mr. T. A. Webster, to whom is due the discovery of the test for the detection of T.N.T. derivatives in the urine. It appears that the reduction condensation compound, azoxy-di-nitrotoluene, is formed, which is excreted in the urine in conjugation with glycuronic acid, and it is this substance which is detected by the Webster test or its modification by Tutin. Dr. Barbara Crawford, at the suggestion of Dr. O'Donovan, tested the effect of the application to the skin of an ointment containing 12½ per cent. of T.N.T. upon one of the patients suffering from toxic jaundice, with the result that no T.N.T. reaction was given by the urine, whereas in a control test on a healthy adult a definite reaction was given. It appears that in severe cases of trinitrotoluene poisoning there may be a failure to excrete the T.N.T. derivative in the urine, and it is therefore possible, as Dr. H. H. Dale suggests, that the absence of Webster's reaction in a person exposed to T.N.T. should be regarded as a danger signal.

Dr. P. N. Panton carried out careful investigations into the pathological changes induced by

¹ No. 53, Special Report Series, 1921. Price 3s. net.

T.N.T. in the human body, and Dr. H. M. Turnbull made very complete histological studies of the changes in the organs from cases in man and animals. The jaundice appeared to be a true toxic jaundice due to destruction of liver by the poison and not to be of haemolytic origin. The aplastic anaemia—the rarest and most fatal of the complications—was found to be due to a direct action of the poison on the blood-forming cells which thus caused a great reduction of the blood-forming marrow. It was not due primarily to haemolysis, though this occurred in the late stages of the anaemia. The blood picture was that of a progressive primary anaemia with high colour index.

The interesting question was considered as to whether progressive changes in the liver were set up in T.N.T. workers after their removal from the influence of the poison. In the severe cases of liver poisoning there was clear evidence of the occurrence of fatal toxic jaundice many months after removal from the influence of the poison, pointing to progressive degeneration of the liver. Where only minor liver damage occurred such evidence as was available suggested that this was recoverable and not progressive.

S. WEIR MITCHELL.

AFTER his death in 1914 the College of Physicians of Philadelphia, for which the late Dr. Silas Weir Mitchell did more than any other man of his generation, founded in his name and memory a triennial oration to deal with "the life and work of Weir Mitchell in their various aspects, or the relation of the physician to public life, or the physician in science or letters, or broad considerations of psychiatry and neurology, or surgery and military surgery in relation to morbid conditions and wounds and injuries of the brain and nervous system, or of scientific research, or medical books and libraries, or medical history and biography, and shall be, as far as possible, of general as well as professional interest." This long list well epitomizes the many-sided activities of his remarkable personality. The first oration, delayed by the war until 1919, was happily entrusted to Dr. C. W. Burr,¹ who reveals a literary gift of a high order, tinged with an attractive turn of gentle satire for the passing foibles of the younger generation. To Weir Mitchell and Sir William Osler the orator gracefully acknowledges his debt for influencing his intellectual life, and for teaching him the paramount necessity for intellectual honesty; it is accordingly with a pupil's reverence that he devotes the first oration to a description of Weir Mitchell as the physician, the man of science, the man of letters, and the man of affairs. The son of a scientific physician, he grew up in a medical atmosphere; otherwise it is probable that his natural inclination would have made him purely a man of letters. His early professional life was a struggle, for financial success was slow in arriving, but he filled in this probationary period by scientific research and did pioneer work on snake venom. The civil war provided him with opportunities for an extensive study of nerve injuries, and his great work, *Gunshot Wounds and other Injuries of Nerves* (1864), gave him a lasting reputation. Among his minor discoveries were the cremasteric reflex and erythromelalgia. His name became widely known in connexion with the rest cure; but, as Dr. Burr points out, it became too popular, and incompetent practitioners adopted it for patients who really were in need of a work cure. The first of his fifteen novels, *Hephzibah Guinness*, did not appear until he was 50, in deference to Oliver Wendell Holmes's advice not to jeopardize his professional prospects; and on this incident the orator remarks that "little-minded people are of the

fixed opinion that no one can have mind enough to do more than one thing." The medical man and the neurologist show up but little in Weir Mitchell's novels, save for the accurate descriptions of really diseased characters, though some of his writings, such as those on dreams and double personality, form a connecting link between science and literature. Dr. Burr suggests that the reason why no medical man of letters has ever succeeded in depicting a doctor is that it is analogous to writing his autobiography or painting his own picture from a mirror; prejudice makes him see what he wants to see. He agrees with Weir Mitchell that George Eliot's Dr. Lydgate is the best description in modern English literature, and dismisses Dickens's doctors as either mere caricatures or silly, sentimental, goody-goody men; he does not mention Thackeray's Dr. Goodenough, generally regarded as a portrait of Elliotson, but perhaps this is too shadowy a sketch. As a poet Weir Mitchell was eminently successful for special occasions, and wrote charming verses on the country. Always interested in physico-therapy he advanced its applications and rescued it from the hands of charlatans; he also took an active part in instituting schools for training nurses and in numerous other public movements. He died in his 85th year when still at work, and almost had the boon that all men should pray for—namely, sudden death. Dr. Burr's tribute may recall Sir William Osler's obituary remarks,² in the course of which he applied to Weir Mitchell the remark made by Samuel Johnson about Mead: "No man ever lived more in the sunshine of life."

INVESTIGATIONS INTO YELLOW FEVER IN MEXICO.

IN continuation of the researches into the etiology of yellow fever in Guayaquil which have been noted in our pages from time to time, making it highly probable that the causal organism is *Leptospira icteroides* and allied to the *Leptospira icterohaemorrhagiae* responsible for the form of infectious jaundice formerly termed Weil's disease, Noguchi, now in collaboration with I. J. Kligler,³ has investigated the disease at Merida, the capital of Yucatan, Mexico. During the four years previous to 1919 a systematic anti-stegomyia campaign kept this city free from yellow fever, but in that year, as a result of an enormous crop of stegomyias, there was an epidemic of yellow fever from July to November, with 100 cases among newly arrived troops, and a death rate of about 50 per cent. Arriving in December, Noguchi and Kligler found opportunities, in one fatal case, a case that recovered, and in convalescent patients, for scientific investigation. Blood drawn from the vein of a patient on the second and third days of the disease, directly transmitted the disease to guinea-pigs, and there were indications of abortive or mild leptospira infection in guinea-pigs inoculated with blood drawn on the fifth day of the disease. Dark-field search for the leptospira in material from the fatal case was negative, but cultures of blood taken on the second day of the disease showed the leptospira. The morphological features and cultural properties of the strain of leptospira isolated from yellow fever in Merida were similar to those of the Guayaquil strains. By means of an anti-icteroid serum, prepared by repeatedly injecting a horse with different strains of *Leptospira icteroides* from Guayaquil, it was shown that the Merida strain belongs to the same group as the Guayaquil strain. Multivalent anti-icteroid immune serum prepared in the horse or univalent anti-icteroid immune serum prepared in the rabbit had a definite devitalizing action on the Merida strain, whereas antisera similarly prepared with strains of *Leptospira icterohaemorrhagiae* did not have any perceptible effect upon the Merida strain. This observation is important not only in showing the relation of the Guayaquil and Merida strains, but also

in answering the criticism that "the yellow fever" in Guayaquil was really an infection with *Leptospira icterohaemorrhagiae*. Anti-icteroides serum protected guinea-pigs against infection, 0.1 c.cm. preventing fatal infection against at least 5,000 minimum lethal doses of the Merida strain, when given during the incubation period or at an early stage of the disease (fever and commencing jaundice), but being almost without effect at a later stage when the jaundice is deep and the temperature falling. If man's susceptibility to *L. icteroides* is comparable to that of the guinea-pig it may reasonably be assumed that intravenous injection of the serum at an early stage would have a similarly beneficial effect. A man weighing 60 kg. would require about two hundred times the amount of serum that a guinea-pig weighing 400 grams would, or 20 c.cm., and, if necessary, the injection should be repeated at intervals of four hours.

CATACLYSMAL HAEMORRHAGE AFTER TONSILLECTOMY.

BLEEDING of great severity is fortunately rare after tonsillectomy, and overwhelming haemorrhage leading to the almost instant death of the patient is amongst the rarities of medicine. A brisk arterial spurting from the tonsil-bed is not very uncommon, particularly in those adults who have a sclerotic, buried, tonsil. In such cases the vessel involved is commonly believed to be the ascending pharyngeal, or more rarely one of the other arteries which supply the tonsil, but abnormally placed or abnormally large. There are, however, in the archives of medicine, records of cases in which the haemorrhage was so appalling that one or other of the carotid vessels was believed to have been injured, no other regional vessel being thought capable of such violent bleeding. Fear of a disaster of this nature was well known to our fathers, and forms the background to a story told of Nélaton. A friend met Nélaton at some distance from Paris, and asked him what brought him thither. "I have just done the operation," he replied, "which takes most out of me. I have removed two tonsils." With this anecdote M. Sebileau¹ closes an exceedingly interesting description of an overwhelming and immediately fatal haemorrhage following tonsillectomy. M. Sebileau was not himself the operator. It was his duty to perform a necropsy on the child in question with a view to the absolution or arraignment of the surgeon. All who prize good writing, and particularly dramatic writing, may be recommended to read M. Sebileau's account of the operation and its sequelae. The possibility of wounding either of the carotids has been doubted by many, and M. Sebileau went to considerable pains to establish beyond doubt the source of the haemorrhage in this case. He injected the two carotids and the internal jugular severally with three different coloured media and was able to show beyond all question that a piece had been cut out of the wall of the internal carotid artery. Precisely how this had happened, how the surgeon went blindly after the upper pole of the tonsil which had escaped removal, and how, hampered by the child's struggles, he cut away the posterior faucial pillar instead, is vividly described. The paper is well documented and contains a useful description of the relationships of the various vessels to the tonsillar fossa. M. Sebileau searched the literature of the subject and has found some eight or more recorded examples. It is not certain that in all of these the carotid was the vessel injured, but the violence of the haemorrhage makes this probable. M. Sebileau has collected also six cases of injury to the carotid inflicted whilst incising a tonsillar abscess. These accidents, when they do occur, are amongst the most painful disasters that can befall a surgeon.

MOTOR FUEL ECONOMY TRIALS.

THE Royal Automobile Club has now issued the regulations to govern its fuel economy trials to take place on the afternoon of Saturday, May 7th, with the object of demonstrating the possibility of obtaining greater fuel economy in the use of cars than is now general. Many private motorists claim to have effected noteworthy economies in fuel consumption, and it is hoped that the trials will give wide publicity to such results and the means by which they are achieved. The Club realizes that the trial will also afford a good opportunity of testing the claims made for the very large number of appliances for reducing fuel consumption that are on the market and concerning which, as has often been pointed out in our motoring notes, the only way in which they can hope to deserve attention is to submit them to official tests. The public has been invited from time to time to spend large sums of money on devices which, it is claimed, effect fuel economy, but in connexion with which it is practically impossible to point to any official evidence in confirmation of the alleged gain. It is therefore noteworthy that one of the regulations wisely allows the judges, when making the awards in connexion with the forthcoming R.A.C. trial, to take into consideration the selling price of any fuel economy device submitted, on the principle that there is no economic advantage in spending £5 to save, possibly, £4 10s. The rules are of a simple character, designed with a view to encouraging the entry of private car owners, who have already shown a considerable interest in the trial and to whom it makes an obvious appeal. A measure of miles per gallon has been chosen as the basis of award for the reason that it is well understood by everyone. In effect, the result will be equivalent to saying that a car of a given make and horse-power, with a complement of passengers, is capable of running efficiently so many miles on one gallon of spirits. That is precisely what the public wants to know. The trial itself will consist of a series of runs from various centres throughout the country, and the date and time have been chosen so that the trial may appeal to a large number of motorists who will be free then. In each locality the course will be a short one. The three classes are for cars not exceeding 12 h.p.; exceeding 12 but not exceeding 20 h.p.; and for those exceeding 20 h.p. R.A.C. rating. These tests cannot be regarded as exhaustive or final. Rather would their usefulness seem to lie in their serving the purpose of eliminating trials of fuel economizers. We should learn which methods and devices are worthy of submission to really searching tests.

THE MEDICAL SOCIETY OF LONDON.

THE 148th anniversary dinner of the Medical Society of London was held at the Warnecliffe Rooms on March 8th, with the President, Sir William Hale-White, in the chair. In proposing prosperity to the Society, the President traced the origins of medical societies, and remarked on the widespread desire that showed itself during the eighteenth century to form clubs and societies. Of the many medical societies founded in that century for the advancement of knowledge and the promotion of good fellowship, the Medical Society of London was one of the few that survived. Sir Anthony Bowlby, President of the Royal College of Surgeons, in proposing the toast of the Imperial Forces of the Crown, confined himself to the work of the medical services, upon whose efficiency the moral and spirit of the nation and of the forces depend so much in time of war. He told the story of how interference with the French Service de Santé by politicians early in 1917 caused temporary demoralization of the French army and nation after the failure of General Nivelle's offensive. Just before the attack the Minister of War did away with the central authority of the medical service, and the consequent breakdown of the arrangements for disposal, transport, and treatment of the wounded gave the

impression throughout France of appalling casualties; false tidings of disaster thus spread up and down the country. In responding to the toast Surgeon Vice-Admiral Sir Robert Hill, Medical Director-General, R.N., paid one more tribute to the services of his civilian colleagues in the Navy during the war, and echoed Sir Anthony Bonlby's hope that, when the time should come for the armed forces to prove themselves again, the medical lessons of the great war would be borne in mind, so that we might start where we left off and not where we began. Major-General M. H. G. Fell, Medical Administrator of the Royal Air Force, also briefly replied. The health of the visitors was proposed in very happy terms by Sir John Bland-Sutton, President of the Royal Society of Medicine, and in responding Lord Justice Atkin, President of the Medico-Legal Society, paid a sympathetic and discerning compliment to the medical profession. Dr. Russell Wells, Vice-Chancellor of the University of London, who also replied, spoke of the value of a university training in producing a good all-round man, as apart from a mere skilled technician, but expressed the view that the three earliest medical universities—Salerno, Bologna, and Paris—all began as technical schools. In briefly proposing the health of the President, Sir D'Arcy Power described Sir William Hale-White as the embodiment of common-sense. A very successful evening ended with a toast to the energetic honorary secretaries, Dr. W. H. Willcox and Mr. H. W. Carson.

CONGRESS OF RADIOLOGY AND PHYSIOTHERAPY. We may remind our readers that the Congress of Radiology and Physiotherapy, organized by the Electro-Therapeutic Section of the Royal Society of Medicine and the British Association of Radiology and Physiotherapy, will be held in London on April 14th, 15th, and 16th, 1921, under the presidency of Sir Humphry Rolleston, K.C.B. The work of the Congress will be divided into three sections—radiology, electrology, and physiotherapy—and at each session papers will be read by representatives of France, Belgium, and England. All communications may be made either in French or English. The subscription for English members is 2 guineas, that for French and Belgian members 40 francs. The Secretary-General is Dr. G. Harrison Orton. Subscriptions should be sent to the honorary treasurer, Dr. J. Metcalfe, at the Royal Society of Medicine, 1, Wimpole Street, W.1.

INTERNATIONAL TUBERCULOSIS CONFERENCE. As we have already announced, the next Conference of the International Union against Tuberculosis will be held on Tuesday, Wednesday, and Thursday, July 26th, 27th, and 28th, at South Kensington, under the auspices of the National Association for the Prevention of Tuberculosis. The Conference will be open to members of the International Union against Tuberculosis and to delegates from countries within the League of Nations and from the United States. It will be presided over by Sir Robert Philip, M.D., Professor of Tuberculosis in the University of Edinburgh, and the opening address will, it is hoped, be given by M. Léon Bourgeois, the retiring President. A discussion on the modes of diffusion of tuberculosis throughout the races of the world will be opened by Professor Calmette. The other subject proposed for discussion is the rôle of the medical profession in the prevention of tuberculosis.

THE "LANGHAM" TELEPHONE EXCHANGE. We announced at the end of November that preparations were in hand for the opening of a new telephone exchange in London to relieve the pressure on the existing Mayfair Exchange, and provide additional facilities in the area between Oxford Street and Regent's Park. The area to be served by the new "Langham Exchange" includes Harley Street and Wimpole Street, and therefore contains a large number of lines rented by members of the

medical profession. On Saturday last the new exchange was opened and the circuits concerned were transferred from the Mayfair exchange. We have received from the Controller of the London Telephone Service a list of telephone subscribers affected who, so far as can be ascertained, are members of the medical profession. The list includes some 450 entries; it can be consulted at the Library of the British Medical Association. The new numbers of all those subscribers whose circuits have been transferred from the Mayfair exchange will appear in the next issue of the *London Telephone Directory*, which is due to be published on April 1st next. In the meanwhile, however, special arrangements have been made by the telephone service both to advise callers of the changes and to divert calls to the new exchange.

At the meeting of the Royal Society on May 5th the Croonian Lecture will be delivered by Dr. Henry Head, F.R.S., on "Release of Function in the Nervous System."

Medical Notes in Parliament.

Dangerous Drugs Regulations.

SIR J. D. REES asked the Home Secretary, on March 3rd, why he would not receive a deputation from those primarily interested regarding the draft Regulations under the Dangerous Drugs Act, and whether he was aware of "the general consternation and alarm at the prospect of the regulation of the sale of drugs in the United Kingdom being dictated by gentlemen at Geneva, having no knowledge of the requirements of those needing and selling drugs in the United Kingdom." Mr. Shortt replied that he was perfectly willing to meet representatives of the different bodies interested and discuss the points they might raise on the draft Regulations. The Regulations had nothing to do with any gentlemen at Geneva; the Dangerous Drugs Act, under which they were framed, was passed in order to carry out our obligations under the treaty of Versailles and the International Opium Convention of 1912.

On a question by Major Barnett, on March 8th, whether the Home Secretary would consider the desirability of exempting duly qualified medical practitioners who dispensed their own prescriptions from Regulations which must necessarily prove irksome and oppressive, and involve an intolerable tax on their time, Mr. Shortt said he had received representations from the British Medical Association as to the records which would be required to be kept by medical practitioners who dispensed their own prescriptions, and he had communicated to them certain modifications which he should be prepared to make in the draft Regulations. The matter was still under consideration. Major Barnett further asked whether the draft Regulations provided that any package or bottle containing specified drugs should have plainly marked upon it the name of the drug and the amount it contained; whether the effect of this provision would be to give patients information which in many cases it was desirable they should not possess; and, if so, whether he would exempt from its operation the prescriptions of duly qualified practitioners. Mr. Shortt replied that he had received representations from the British Medical Association on this point, and had informed them that he was willing to agree to the exception suggested.

On a third question by Mr. Kiley as to the position of farmers, Mr. Shortt said that the whole question, including a suggestion as to the possibility of denaturing the drugs supplied for use by farmers, was under consideration, but he was not in a position to make any statement at present.

Proprietary Medicines Bill.

Captain Tudor Rees asked, on March 2nd, whether the attention of the Minister of Health had been called to the advertisement of alleged cures of cancer and other diseases, and whether he would introduce legislation to protect the public from the frauds and deceptions of advertisers. Dr. Addison replied that the Proprietary Medicines Bill, introduced last session, was intended to give effect to the recommendations of the Select Committee, which reported on this question in 1914. The bill was now being revised to meet certain objections of the commercial interests concerned, and he hoped it would be possible to reintroduce it during the present session, but he was unable at present to name any definite date.

Medical Record Cards.

Mr. Forrest asked, on March 2nd, whether the Minister of Health was still receiving any protests from panel doctors as to the work entailed by filling up the new forms of cards; and, seeing that the time so employed diminished the amount of attention that could be given to individual cases, whether he would inquire into the whole matter to see how the system was working. Dr. Addison replied that he could not accept the view that the keeping of records must detract from the time available for giving adequate medical treatment. In the majority of insurance practices the practitioner was responsible for less than one-fourth of the number of insured patients for which, in the view of the doctor's own representatives, an ordinary practitioner could safely assume responsibility. The number of objections from medical men and others concerned in working the system was insignificant. Out of some 150 Panel Committees, representing some 12,000 medical men on the panel, he had received protests from only nine, and those mostly on points of detail, although every effort had been made by certain persons to stir up discontent.

On further question on March 7th by Mr. Myers, Dr. Addison said that the number of complaints he had received about insurance medical records was quite insignificant, consisting of representations from five only out of 10,000 approved societies and branches, none from any of the Insurance Committees, and, as previously stated, nine, mainly on points of detail, out of 150 Panel Committees, representing medical men on the panel. The card was in substitution for two others used since the commencement of the Act, and had been designed mainly to give insured persons the advantages enjoyed by private patients in those practices where doctors kept records, and therefore were enabled to be guided in treating current symptoms by reference to the patient's previous medical history. Mr. Dennis Herbert asked whether it was not the case that one of these later cards was given up because it was practically impossible for doctors to complete it. Dr. Addison said that was quite true, and that was one reason why the revised card was designed. The new card certainly gave much less trouble than the old one. Mr. Herbert said he had studied the card with several doctors, who took a totally different view. Dr. Addison replied that the new card was designed by doctors, mainly by panel doctors, with a view to assisting them in their practice.

Industrial Fatigue Research Board.

Questioned by Captain Cooté and Mr. Mills as to the reported decision of the Treasury to withdraw financial support from the Industrial Fatigue Board, Dr. Addison said that the expenditure on the Board was naturally being reviewed with all other public expenditure in the light of the imperative need for economy. The Board itself would be continued, and he thought he could safely promise that sufficient funds would be provided to secure its efficiency.

Security of Tenure for Public Medical Officers.

Sir Philip Magnus asked, on March 2nd, what progress had been made in giving effect to the promise contained in Dr. Addison's letter of May 31st, 1920, in pursuance of a previous promise of the Local Government Board to proceed with an order to give security of tenure to whole-time medical officers. Dr. Addison said he was advised that legislation would be required to afford this security of tenure to existing officers, and the Order which would shortly be issued must therefore be confined to new appointments.

Standardization of Serums, etc.—Sir J. D. Rees asked, on March 7th, whether the Minister of Health was devising a series of expensive measures relating to the control of serums and therapeutic substances, including a controlling authority, a big central laboratory and other machinery in consequence of a report of a recent departmental committee appointed to consider the subject. Dr. Addison said the question clearly referred to a report contained in a leading article in the Times of February 25th. There was no truth in the suggestion that he was devising any measures of the kind indicated. From 1909 onwards, suggestions had been made by the General Medical Council and other influential bodies for some method for standardizing serums and other medicinal means. In this desire the responsible drug manufacturers appeared to concur, and it should be remembered that some of these substances were made abroad as well as in this country. The Committee reported to him during January of this year, and the chairman (Sir Mackenzie Chalmers), on his own responsibility, suggested a draft bill. When the matter

came before him (Dr. Addison) in January, he took the view that action on the lines indicated by the proposed bill was not practicable. So far as he had examined the subject the Committee appeared to contemplate that the Medical Research Council, which already had laboratory equipment, should supervise the carrying out of whatever test proved to be required. No action whatever had been taken upon the report, nor any recommendation made to his colleagues. The intentions attributed to him were entirely fanciful.

Mortality from Tuberculosis.—In reply to Lieut.-Colonel Raw, Dr. Addison said, on March 3rd, that although the conditions of active service no doubt increased the mortality from tuberculosis in weakly men, and in those already suffering from tuberculosis, he was advised that there was no evidence to show that there had been any increase in mortality from this disease among men who were healthy upon entering on naval or military service. The latest statistics indicated that there was a number of deaths from tuberculosis including both pulmonary and pleurisy for 1915 being 46,312, as against 351 in 1917. The figures for 1920, so far as they were at present available, indicated another decrease.

Veneral Disease Report.—Lieut.-Colonel Fremantle asked, on March 2nd, whether the attention of the Minister of Health had been called to the report of the Special Committee on Veneral Disease, recently published, and to its recognition of the value of immediate self-disinfection; and what steps were proposed to be taken by his department in the matter. Dr. Addison replied that the subject was now under consideration. All the relevant documents and evidence, including the report mentioned, would be considered.

Disability Pensions.—Colonel Gibbs, on behalf of Mr. Macpherson, stated on March 3rd that the number of cases in which a pension had been refused to an ex-service man on the ground that the disability on which he claimed was not due to service, was 25,700. In the case of widows the records of the Ministry did not show refusals before April 1st, 1920; the number of rejections since that date was 6,920. In all cases of refusals, whether of men or of widows, there was a right of appeal. Colonel Gibbs added that a man had a right of appeal to a medical board on the question of assessment, and to an independent tribunal on the question of attributability. On further questions Colonel Gibbs stated that the appeal tribunals had heard and decided 1,978 appeals lodged by widows against decisions by the Ministry that the disease from which the husband died was not contracted in, nor aggravated by, his service. Of those appeals 523 were allowed and 1,455 rejected. The decisions of the tribunals were final. These appeal bodies consisted each of one doctor, one lawyer, and an ex-service man. Major Glyn asked, on March 3rd, whether the Minister of Pensions was aware that in the event of a dependant entering a rate-aided institution—for instance, a lunatic asylum—the pension to which such an individual was entitled was suspended during the period of detention, and whether the Minister would consider the desirability of paying it to the local authorities for the relief of the rates, until such time as the man emerged from the institution. Colonel Gibbs said the matter was under consideration.

Housing and Tuberculosis Bills.—On inquiry by Mr. Ormsby Gore, on March 3rd, Dr. Addison announced that he proposed to introduce the Housing Bill and the Tuberculosis Bill before Whitsuntide.

Food Values.—Captain Elliot asked, on February 25th, if the Minister of Health would consider whether information regarding nutritive and economical foods could be circulated to local authorities, education authorities, and the press, in view of the present distress and the great amount of manufactured and semi-manufactured food consumed by the people of this country. Dr. Addison replied he was considering whether it would be practicable to issue a pamphlet containing information on the lines suggested. It was difficult to make any general statements with regard to the values of food which were not liable to be misconstrued. He was having certain researches conducted on the subject in connexion with the Medical Research Council.

Maternity and Child Welfare Centres.—In answer to Sir Keith Fraser, on March 2nd, Dr. Addison said that according to the latest available information 43 persons (of whom 25 were men) were appointed during 1920, specifically as medical officers of maternity and child welfare centres, the annual rate of remuneration not exceeding £11s. 6d. per session, and amounting in the aggregate to about £3,660 per annum. In addition 36 persons (of whom 10 were men), were appointed by local authorities during this period, as whole- or part-time medical officers for maternity and child welfare work generally, at salaries varying from £150 to £750 per annum. These duties included in every case more or less direct supervision of the work of centres, but it was not possible to make any apportionment of the salaries for that purpose, or to estimate, even approximately, what proportion of annual cost of welfare work was attributable to this branch of the service. Milk and, in special circumstances, other food might be provided at less than cost for expectant and nursing mothers, and for children under five years of age, when such provision was certified by the medical officer of health for the centre or by the medical officer to be necessary and where the case was necessitous.

surgeon, for it is full of suggestion, and should point out to them the importance of pre-operative treatment, especially of mammary carcinoma, which is so largely neglected by English surgeons as compared with American surgeons.

I have seen it too often to have any doubt on the subject, that operation for mammary carcinoma, of even the most favourable type and done in the most thorough manner by the most capable surgeons, is followed in a large percentage of cases by rapid dissemination, which I am sure could have been averted by pre-operative treatment; whether by direct action on the carcinomatous cells, by its constrictive action on the lymphatics, or, as suggested in the paper above referred to, by its action on the blood, matters not.

Returning again to the subject of small doses stimulating malignant growth, I am anxious to find out whether or not this is one of the "myths" that are constantly copied from one writer by another and so perpetuated in medical literature, and I should therefore be exceedingly grateful to any one who can give me any evidence, experimental or otherwise, to prove the statement.—I am, etc.,

Bradford, March 1st.

WILLIAM MITCHELL.

THE SEARCH FOR A SPECIFIC TREATMENT OF TUBERCULOSIS.

SIR,—In view of the article under the above heading in the BRITISH MEDICAL JOURNAL, February 26th, 1921, which appears to be, so far as I know, the first indication of the general nature of Mr. Henry Spahlinger's treatment, may I be allowed to point out that investigations on parallel lines, as it seems to me, have not been altogether neglected in this country?

It is stated that Mr. Spahlinger's injections consist of "a combination of tuberculous antigens and of ferments" combined with "auxiliary treatment composed of ferments associated with lipoids."

During the past few years my attention has been concerned with lipase,¹ the lipolytic or fat-splitting ferment, and from experimental work carried out in the physiological and bacteriological laboratories, King's College, I² have concluded that in induced tissue lipolysis an explanation is afforded in part of natural and therapeutic immunization—that is to say, the main idea or principle underlying treatment in bacterial disease is, as I have suggested, the production of the lipolytic or fat-splitting ferment in the tissues, which in tuberculosis acts on the fats and lipoids of the tubercle bacillus, and is injurious to it. As I have shown, there are a number of substances which have the power of increasing or stimulating such lipolytic or fat-splitting action *in vitro* and *in vivo*. This property is shared by serum proteins, various tissue extracts, sodium oleate and inorganic salts, such as the phosphates and salts of calcium.

The same principle in part underlies treatment by vaccines and tuberculins, in which activators or co-enzymes of the fat-splitting ferment are present in varying degree. The tubercle bacillus itself is known to contain proteins, lipoids, fatty acids, phosphates and calcium, in addition to a large amount of fats and waxes. I have preferred to adopt the nomenclature of activators or co-enzymes rather than "antigens," because the former more correctly indicate the part played in the production of the lipolytic ferment. But to which of such activators or co-enzymes a therapeutic effect may be due is uncertain.

In drawing attention to this interpretation of the action of vaccines and tuberculins, I³ suggested at the same time that "the products of ferment and bacterial digestion" might prove more serviceable than vaccines. In this connexion the serum of patients recovered from tuberculosis markedly accelerates or activates the fat-splitting action, compared with a decreased power in the acute stages. The former contains, as I concluded, the products of digested or partially digested tubercle bacilli, the result of the lipolytic or bactericidal action. Such products—namely, fatty acids or particular soaps derived or prepared from the action of the lipolytic ferment on the fats and lipoids of the tubercle bacilli—may not only be protective or

act as stimulants to lipolytic activity, but the initial action of the ferment may liberate other contained activators. The presence of proteins or lipo-proteins in the tubercle bacillus does not exclude the products of proteolysis in action secondarily, as such induced tissue ferments cannot in view of the fatty capsule of the bacillus, be expected to act primarily. Similar products conceivably result from the growth of the living bacteria in the tissues or in nutrient media, or as a result of autolysis.—I am, etc.,

London, March 1st.

J. A. SHAW-MACKENZIE, M.D. Lond.

THE RETARDED CINEMA AND CARDIAC ACTION.

SIR,—Referring to the interesting demonstration of the retarded cinema which Dr. Monod-Walter gave last week at the Royal Society of Medicine, your annotation (March 5th, p. 359) states that his second film, that of the isolated mammalian heart, showed "what most British students of to-day have seen in the laboratory." This is so as regards the film showing the normal rate of cardiac movement, but not, I think, as to what the retarded film showed. Someone had suggested that the films showed auricular fibrillation, possibly because the auricles exhibited little activity. The action of the heart was, however, regular, which is scarcely compatible with usual conceptions of auricular fibrillation. The auricles were, in fact, distended by the method used for maintaining the circulation.

The point, however, of most interest shown by the retarded cinema was a condition the existence of which is disputed by many, and which the film of the normal rate did not show—namely, a distinct hemisystolic action of the ventricles. Noting this at the first demonstration, I also attended the second, and was confirmed in my impression that contraction of the right ventricle preceded that of the left in the retarded film. A film, however, still more retarded would show the condition better. Should it be possible to photograph movements of the heart by the retarded cinema through the fluorescent screen the method might be of clinical interest, if not service. For, although in dissociated auriculo-ventricular action the greater rate of auricular over ventricular movement may be seen by the naked eye through the screen, a retarded picture would show this condition much more easily. This state, however, may be easily determined by other methods already in use. But the existence of ventricular hemisystole, in which from clinical observation I personally believe, would be more generally acknowledged were the retarded cinema found to show this state indubitably, as I think, with a little increased retardation, it would do. Nor would this be merely a matter of curiosity, for it would help to explain certain physical signs detected by auscultation.—I am, etc.,

London, March 7th.

ALEXANDER BLACKHALL-MORISON.

THE CURE OF HAEMORRHOIDS WITHOUT OPERATION.

SIR,—The article by Dr. Lyth and the letters which it has called forth appear to me to typify the attitude very often adopted by medical men in advising patients.

The number of conditions where the practitioner is justified in telling a patient that he *must* be operated on is relatively small; on the other hand, there is a multitude of disabilities where operation alone offers anything like a certainty of cure. I mean, of course, such diseases, to name but a few, as piles, chronic appendicitis, pyloric ulcer, gall stones, hernia, varix, prolapsus uteri, etc.

Surely the only course which an entirely unprejudiced doctor is justified in taking in such a case is to state the alternatives as clearly and fairly as possible to the patient and leave him to make the choice, instead of practically insisting upon his adopting whichever alternative appeals to the practitioner's predilections.

In a condition such as that described by Dr. Lyth I should be inclined to say to the patient: "You are suffering from engorged piles; the engorgement can be got rid of by medicine and local applications, after which you may, by carefully regulating your life, go along fairly comfortably, perhaps for many years; on the other hand, if you wish to be able to lead an entirely normal life and to be free from rectal discomfort, the only certain remedy I know is the removal of the diseased veins by surgical means."

¹ *Proc. Roy. Soc. Med. (Therap. and Pharm. Section)*, V, 1912, p. 152; *Internat. Congress Med., London (Therap. Sect.)*, 1913; *Journal of Physiology*, xlix, 1915, p. 216.

² *Lancet*, 1919, ii, p. 825; *Med. Press and Circular*, 1920, ii, pp. 122 and 460.

³ *Med. Press and Circular*, 1915, ii, p. 190.

Many patients will decide to lead a modified life rather than submit to operation, but many others (and we may surely rejoice that it is so) will act according to the Stevensonian axiom that "the love of living is stronger in an Alpine climber roping over a peril, or a hunter riding merrily at a stiff fence, than in a creature who lives upon a diet and walks a measured distance in the interests of his constitution," and will wish for curative rather than palliative treatment.

I am convinced that an enormous amount of defective health is the result of failure on the part of medical men and women to point out clearly the pros and cons of surgical treatment; that this is so is illustrated by the frequency with which patients whose lives have been made fuller and more comfortable by operation tell me that they would have had the operation done earlier had not their doctor definitely dissuaded them.—I am, etc.,

Bradford, March 6th.

JAMES PHILLIPS.

Sir,—I had anticipated that critics of the method which I advocated would not be wanting. I had, however, expected them to be found in the ranks of surgery rather than of medicine.

Dr. Copeman's letter amounts to a direct negative, unsupported by either theory or practice, which does not form a basis for discussion. He is welcome to his little joke; but if he reads my article again, he will see that I quite recognize that certain haemorrhoids cannot be replaced within the sphincter ani, and indeed, that it is preferable that no undue attempts should be made to treat them in this way. His sorrow and his hilarity will therefore be wasted in my case.

Dr. Morley's criticisms, on the other hand, strike at the basis of the treatment which I adopt, and if they were justified no lasting results could be obtained in this way. I do obtain such results, so I am constrained to examine his criticisms for the flaws which they must contain.

There are two main questions at issue: (1) Whether internal haemorrhoids can become external haemorrhoids; and (2) whether internal haemorrhoids cause severe symptoms without prolapsing.

In regard to the first question, which Dr. Morley answers with an emphatic negative, I am afraid he is assuming that the condition in which he finds the parts is that in which they have been more or less throughout the course of the disease, and in which they remain throughout the changing conditions of everyday life. I am aware that his view, while not definitely stated, is that tacitly assumed by most authors. Yet this is by no means entirely so; and although I am in the habit of preferring my own observation, when practicable, to that of others, I find that Walsham and Spencer (*Theory and Practice of Surgery*) describe three kinds of piles—the internal, covered with mucous membrane; the external, covered with skin; and others, "in many instances covered in part with skin and in part with mucous membrane," which they refer to as "mixed piles." This condition, I take it, is produced when "internal piles" have been outside long enough for the process of conversion to "external piles" to be taking place. Keen describes a fourth variety as "false piles," the tags of skin into which, in my view, the piles when cured become converted. We have thus the complete sequence I described. Moreover, all authorities agree in describing the etiology of internal and external piles as identical, and all agree that internal piles may become permanently prolapsed and yet may be spontaneously cured in that position. One cannot help wondering what an "internal pile" outside the anus, still covered with mucous membrane and yet cured, looks and feels like.

From the point of view of clinical experience my own observation leaves me not the slightest doubt that, as I stated in my article, the distinction between internal and external haemorrhoids is purely artificial. It may be that Dr. Morley has not been under the necessity of watching the course of an individual pile for several years, day in and day out. I have had that experience, and I assert that without a doubt it began by prolapsing occasionally, and ended as a tag of skin. From correspondence which I have had with other practitioners I know that I am not alone in this view; but even if I were, "seeing is believing." That there is nothing histologically unique in mucous membrane giving place

to skin when exposed to conditions outside the body will surely be admitted—for example, the glans penis after circumcision.

This assumption that the relation of the parts during examination is necessarily or even probably that existing during the whole twenty-four hours is evidenced even more markedly in Dr. Morley's second contention: that internal piles cause severe symptoms without prolapsing. If he had read my article a little more carefully he would have noticed that I stated that "so long as it is inside and remains inside—even during defaecation—it does little harm." He assumes, because he finds piles inside the anus causing haemorrhage, etc., that these symptoms occur while the piles are inside. In the same way, until comparatively recently the stomach was regarded as a "stomach-shaped" organ because its post-mortem appearance gives this definite shape. It is only since x-ray examinations with bismuth meals have shown that it is rather to be regarded as a muscular tube that a true conception of its condition in the living body, under the changing demands of digestion, has been arrived at. Likewise, Dr. Morley regards the anus as a canal having a certain lining; he does not appreciate the fact that this lining is normally protruded to a marked degree during defaecation. Yet a very little observation, of animals no less than of human beings, should have made him realize this. The erectile tissue remaining as a vestige of reptilian life lends itself to this, no less than the musculature and heavy pressure from above. Keen states, in regard to internal haemorrhoids, that "the physician will secure a demonstration of them by having the patient strain in the squatting posture after enema." Furthermore, how can a pile bleed externally (excepting the negligible quantity which is passed along with the motion) unless it is prolapsed? In point of fact the most severe haemorrhages take place after the motion, while the patient is still at stool, with the haemorrhoids prolapsed, the blood often squirting in all directions as from a cut artery. Yet after time has been allowed for their replacement—perhaps soon and automatically—such a patient may be examined without any prolapse being found or stated to have occurred. Such piles Dr. Morley would regard as having never prolapsed. Yet if the bleeding were to take place inside the anus and above the sphincter the experience would be that a quantity of blood would accumulate to be passed in front of the next motion; it would be dark and clotted. In point of fact the blood comes after the motion, and is bright red and fluid. It is while such haemorrhoids are thus temporarily prolapsed, immediately after a motion, that it is possible to apply the treatment which I have advocated; and in my view, unless there is at least temporary prolapse, there are no serious symptoms.

So much for the pathology. In regard to treatment, Dr. Morley is guilty of distortion in assuming that I suggest that a patient who has undergone this treatment must afterwards wear a pad and powder the piles frequently. I said nothing of the kind. I advised that he should have a pad and calamine powder available. In point of fact, beyond the nocturnal defaecation, which I would in any case advise even after operation, I have not found that any further treatment, such as the application of the powder, is necessary, unless undue constipation or an attack of diarrhoea has been experienced. To point a comparison of this state of affairs with that after operation, I am at this time instituting treatment in the case of a lady who had her haemorrhoids removed by operation some five years ago.

I cannot discuss from experience Dr. Morley's treatment by injection; but I notice that even this treatment is not instantaneous nor very simple, as he says that the injections must be repeated at weekly intervals (for an indefinite period), which does not entitle him to the scorn with which he regards the six weeks I have specified as an average space of time. Moreover, I find that Warbasse (*Surgical Treatment*) regards injection with phenol as dangerous. He says, "Pyemia and hepatic abscess have followed this treatment," and that it is "justified only when the patient understands the risk, when an anaesthetic cannot be administered, and when a surgeon capable of performing a safer operation cannot be had." In the face of such a warning I prefer to go on curing my patients in my own way, which is safe, if not heroic.—I am, etc.,

York, March 5th.

J. C. LYTH, M.B., B.S.

PUERPERAL INFECTION.

SIR,—There have been many articles of late on this subject, but it seems to me that many of the writers do not fully realize the conditions under which the average practitioner has to work. The question of perfect asepsis is after all very largely one of expense. It is suggested that we should arrive at our cases armed with drums of sterile gowns, dressings, towels, gloves, and other impedimenta, as for a surgical operation in a fully equipped hospital. To use these properly we should require at least two capable trained nurses, and for most cases a qualified assistant. We should also have to have a room to work in suitable to accommodate all the impedimenta we brought with us.

The other side of the picture is provided by our actual experiences. Our equipment has to be of such dimensions as can be carried on a bicycle or motor cycle or in our hands; our only assistant is usually an untrained monthly nurse or a relative of the patient; there is frequently a lamentable deficiency of the ordinary articles of utility. The patient has almost invariably a fully loaded rectum, which empties itself during the passage of the head over the perineum, infecting everything within a radius of a yard or so. The doctor has to apply the forceps or do other operations and give the anaesthetic at the same time, because the extent of the money available is in the neighbourhood of £2 (to include attendance for ten days). To carry out the precautions necessary to ensure absolute asepsis—which most of us fortunately desire—would involve an expenditure of at least £10 to £15, and probably more.

Under present conditions the most careful practitioner cannot help getting a certain, though fortunately small, proportion of cases which get some degree of infection. Perhaps in the remote future confinements will be made compulsory in properly equipped State lying-in hospitals where expense will be no object, but until then we shall not reach our Mecca of perfection.—I am, etc.,

H. W. OGLE-SKAN, M.R.C.S., L.R.C.P.

Hendon, N.W., March 6th.

RISKS AFTER OPERATIONS ON TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—The recent correspondence on this subject has described nothing that was not known to us all, with the possible exception of one or two favoured individuals. We should all like these operations done under better conditions. Neither the general public, nor the subscribers, nor hospital boards of management are ignorant of the facts. The correspondence leads nowhere. Dr. Andrew Little says that his worst cases have been private cases carefully attended to in good nursing homes. Exactly so. It would be quite easy, on the other hand, to demonstrate surprisingly good results from the present system.

The only point that appears to have been really established is that an occasional case will give trouble or go wrong whatever the conditions may be. Within my experience there has been vast improvement, speaking generally, in the circumstances under which these operations are done. This improvement can continue, and no doubt will continue. Most people know that counsels of perfection are out of the question at present in most places.—I am, etc.,

T. JEFFERSON FAULDER.

London, W., March 2nd.

FATAL POISONING FROM ACID FUMES.

SIR,—I was greatly interested in Dr. T. Gillman Moorhead's communication in your issue of January 15th, under the heading of "Fatal poisoning from the inhalation of acid fumes in a laboratory." It is apparent from the very wording of this heading that Dr. Moorhead was unable to arrive at an exact diagnosis.

To my mind the course of events becomes very clear by a process of analysis and exclusion. In the first place, of the three compounds with which the unfortunate student was working, one only could give rise to fumes of such toxicity by the action of sulphuric acid—namely, the stibnite. If this were an impure sample, if there were any metal present, such as iron or zinc, forming hydrogen with this acid, or if such a metal had been wilfully introduced in the course of the experiment, it is highly probable that stibine, or antimoniated hydrogen, was evolved. This gas is intensely poisonous, and practically odourless.

On looking through Dr. Moorhead's notes of the case we find two separate sets of symptoms: the earlier consistent with direct irritation of the respiratory tract by the inhalation of the acid fumes—trivial in itself and of almost daily occurrence in a big chemical laboratory—and the later due to absorption of some poison into the system. And these later symptoms—namely, furred tongue, rapid feeble pulse, weakness and loss of weight, diarrhoea, albuminuria, icterus and hepatic enlargement (due, doubtless, to fatty degeneration)—are a perfect picture of antimony poisoning.

Was a *post-mortem* examination made? The presence of a sufficient quantity of antimony in the body to carry out Marsh's test would almost certainly have clinched the diagnosis. As regards prognosis, the case was probably hopeless from the outset owing to the difficulty of eliminating antimony absorbed in such a way.

As regards its importance to laboratory workers, I think the lesson to be learnt is that the fume chambers in this particular laboratory are not effectively ventilated for work with lethal gases.—I am, etc.,

WILLIAM CORBET, M.B.

Point Fortin, Trinidad, Feb. 10th.

PREVENTION OF VENEREAL DISEASE.

SIR,—I think some of the objections to the issue of prophylactics to the civil population are, briefly, as follows:

The issue of such preventives tends to undermine that reasonable and natural self-control which is the truest safeguard against disease. Self-disinfection increases the number of men who expose themselves to infection, is admittedly unreliable, and will eventually increase disease. It is useless and inconsistent to instruct the young on matters of sex, including the advantages of continence, and at the same time to countenance the issue of prophylactics. Early marriages reduce the prevalence of venereal disease. The encouragement of illicit intercourse means fewer marriages and less family life.

The issue of prophylactics is unscientific. It does not attack the real causes of the trouble. Such a policy tends to direct attention away from those social, economic, and hygienic reforms which have a real and lasting influence in reducing venereal disease.—I am, etc.,

L. C. ROWAN-ROBINSON, M.B.

Lilbodi, South Africa.
Feb. 6th.

Obituary.

SIR FELIX SEMON, K.C.V.O., M.D., F.R.C.P. LOND.,
Honorary Consulting Laryngologist, National Hospital for Paralysis;
late Physician Extraordinary to H.M. King Edward VII.

It is with deep regret that we record the death of Sir Felix Semon on March 1st at his residence, Rignalls, Great Missenden, at the age of 72 years.

Felix Semon was born at Danzig on December 8th, 1849, the son of a stockbroker, and began his medical studies in 1869 at Heidelberg. He served in the Franco-Prussian war of 1870 as a volunteer with the 2nd Uhlans of the Prussian Guard. After the war he returned to Berlin, and graduated M.D. in 1873. He then went to Vienna and Paris for post-graduate work, devoting his attention especially to diseases of the throat, a department of medicine then in its infancy, but destined to far-reaching developments, to which Semon in his lifetime contributed so largely.

Semon was appointed a clinical assistant at the Throat Hospital, Golden Square, London, in 1875, where his exceptional talents and capacity for scientific research were quickly recognized and led him to decide to settle in London. In 1876 Semon was admitted a Member of the Royal College of Physicians of London, and in 1885 became a Fellow of that College. He was elected in 1877 to the honorary staff of the Golden Square Hospital, and in 1882 physician in charge of the Throat Department of St. Thomas's Hospital, where he founded the special clinic to which his rapidly increasing reputation as a sound and reliable teacher and practitioner, attracted a great many students and practitioners. In 1888 he was appointed laryngologist to the National Hospital for the Paralysed and Epileptic, where he had opportunities for the special investigation of the neurological problems in laryngeal paralysis and other throat affections, to the elucidation of

which he had already devoted himself with signal success, and, with his friend the late Sir Victor Horsley, entered on clinical and experimental researches which made for British laryngology a world-wide reputation.

The Laryngological Society of London was founded by Semon in 1893, and he was its President for three successive years, 1894-1896. When later the Royal Society of Medicine was incorporated, Semon took a leading part in bringing together the British Laryngological, Rhinological, and Otological Societies, and the Laryngological Society of London. By their coalescence the Laryngological Section of the Royal Society of Medicine was constituted. He continued to devote his best energies to the meetings of the Section, and by his genial presence, enthusiasm, and scientific work he contributed greatly to its success. He was president of the Section of Laryngology at the annual meetings of the British Medical Association in Glasgow in 1888 and in London in 1895.

Semon's original contributions to his speciality were of great value, but far too numerous even to mention here in detail. Perhaps the more notable were those on laryngeal neurology and on malignant growths of the larynx, the series of articles on diseases of the pharynx, larynx, and trachea contributed to Allbutt's *System of Medicine* in collaboration with Watson-Williams, on malignant growths of the larynx in the *Encyclopaedia Medica*, and articles in Heath's *Dictionary of Surgery*, and in Heymann's *Handbuch der Laryngologie*. He was the founder and for twenty-five years the editor of the *Internationales Centralblatt für Laryngologie und Rhinologie*, while his own *Forschungen und Erfahrungen*, 1880-1910, is a work of great value and lasting interest.

In the early eighties his clinical investigations had led him to the conclusion that in all progressive organic lesions of the centres of trunks of the motor laryngeal nerves, the abductors of the vocal cords succumb much earlier than the adductors. He strengthened his deductions, based on clinical work by experimental research in conjunction with Sir Victor Horsley. After a long controversy with various noted laryngologists, who sought to explain the facts by other theories, Semon successfully upheld the accuracy of his observations, and succeeded in establishing his thesis as a clinical fact of considerable interest and import, which is known and recognized as "Semon's law." Semon's contributions to the early diagnosis and operative technique of malignant growths of the larynx, more especially the indications for thyrotomy in intrinsic laryngeal cancer, were notable. The successful results obtained from removal by laryngo-fissure in suitable cases by Butlin induced Semon to adopt that route at a time when the intralaryngeal method was practised and commended by some leading European authorities. But it was essentially Semon's elaborated and accurate methods of differential diagnosis, of such practical import for the early recognition of malignancy while still amenable to successful eradication by laryngo-fissure, that placed this operative measure in the unassailable position it has continued to occupy. In Semon's own hands a lasting cure was obtained in over 80 per cent. of the cases he operated on for malignant laryngeal growths, and through the adoption of his successful diagnostic and operative practice, by most laryngologists throughout the world, his work has proved of immense and lasting benefit to humanity. Furthermore, these methods of early diagnosis, by avoiding the necessity for more drastic and maiming operations, have been the means not only of saving many lives, but a large number of patients who have undergone a radical operation for laryngeal cancer are restored, without losing their voice, to a useful and happy life.

Semon's scientific mind could not tolerate inaccuracy, and he was relentless in pursuing what he deemed error in observation or statement in others. In his early days prejudice against specialism and specialists was in many quarters strong, and sometimes found intemperate expression. Semon was always ready to speak for the defence; he did not mince his words, and became engaged in several rather heated controversies. He was a regular attendant and frequent speaker at the meetings of the medical societies. His reputation as a consultant for diseases of the throat brought him a large laryngological practice; which he continued to enjoy till he retired in 1911 at the zenith of his career. Expression was given to the esteem in which he was held at the banquet organized to mark the occasion of his retirement, when the late Sir Henry

Butlin presided over a gathering comprising the great majority of British laryngologists, as well as many distinguished foreigners and a large number of musicians, artists, literary and other friends. A sum of £1,040, subscribed as a testimonial expressive of their warm regard for him and appreciation of his life's work, he presented to the University of London to establish a trust for the purpose of awarding a commemorative bronze medal for the best work in the treatment of diseases of the throat and nose and to found a lectureship to be called the "Semon Lectureship in Laryngology." Anxious as he ever was to promote the authoritative position of the Laryngological Section of the Royal Society of Medicine, it was by Semon's special request that two members of the board by which the lecturer is appointed are elected by this Section.

Semon was honoured by the confidence of H.M. Queen Victoria, who conferred the honour of knighthood upon him in 1897; later he was appointed Physician Extraordinary to H.M. King Edward VII and received the K.C.V.O. in 1905. In 1838 he had received the Order of the Red Eagle, and in 1894 the German Emperor conferred on him the title of Royal Prussian Professor. During his lifetime he was honoured by almost every laryngological society in Europe and America. He was an Honorary President of the Madrid Laryngological Society and Honorary Fellow of the Italian, Petrograd, and American Laryngological Associations. To no other laryngologist has fallen such a world-wide recognition as came to Felix Semon. With it all, there was never a kindlier and more considerate friend to younger practitioners, ever anxious to bring out and encourage the latent talent that he was often the first to discover and to promote.

We have but touched on the main features of Semon's life as a physician known for his work in laryngology, yet we cannot leave our tribute to his memory without reference to some of his other attributes. He was not only an accomplished pianist, but as a composer displayed talent of no mean order; as a raconteur he was delightful, as a friend he was ever true and steadfast, a thorough sportsman, a fearless rider and a keen deer stalker, as the many heads adorning his mansion at Great Missenden testify.

Semon's geniality and courtesy, his vivacious conversation and generous hospitality, rendered him a conspicuous figure in society, but by his many friends he was loved for his warm heart and unswerving fidelity. Latterly increasing ill health compelled him to live a very quiet life, and almost entirely at Rignalls, which he had designed and built, devoting much of his time to literary pursuits and to his garden. A little more than a year ago he underwent a severe operation, and, though he recovered from this, he never regained his old energy, but his last illness, which so rapidly proved fatal, was quite unexpected.

To the last he never failed to maintain a keen interest in affairs, and particularly in the speciality he adorned, and all that concerned the progress and advancement of laryngology in this country. A recent example of this is furnished in connexion with the famous Onodi collection. "This country ought to possess the collection," said Semon to the writer on hearing from the late Professor Onodi's son that it was for disposal; and it was Semon's initiative that led to the collection being brought to London to that end, although after its arrival here, as is common knowledge, the credit of securing it for this country belongs entirely to two of his colleagues and to those who supported their successful effort.

He married in 1879 Louise Dorette Augusta, daughter of H. Redeker. To Lady Semon and their three sons we tender our deepest sympathy. His eldest son, Dr. Henry Semon, is practising as a dermatologist. In the late war Felix Semon himself repeatedly offered his services, but at his advanced age he had to be content with sending his three sons.

SIR CHARLES ALEXANDER CAMERON, C.B., M.D.,
Medical Officer of Health, Dublin.

We announced briefly in our last issue the death of Sir Charles Cameron, C.B., which occurred in Dublin on February 28th, in his 91st year. Born in Dublin on July 16th, 1830, the son of Captain Even Cameron, of Lochaber, Charles Alexander Cameron received his early education in Dublin, afterwards going to Germany, where he graduated Ph.D. in 1856. He obtained the L.R.C.P.I. in 1868, becoming a Fellow of the College in 1893, and he

became F.R.C.S.I. in 1874. He held the D.P.H. of Cambridge and of the Irish College of Surgeons, and was made an honorary M.D. of the Royal University of Ireland in 1896. In 1867 he was elected professor of hygiene in the Royal College of Surgeons of Ireland, and for more than half a century he had charge of the public health of the city of Dublin, where his greatest public services were rendered. Upon many occasions his opinion was invited by public bodies abroad as well as in Ireland, and he always readily placed his great experience at their disposal. As a sanitary scientist his name was known throughout Europe, and he was elected to the honorary membership of a number of foreign learned societies, including the Swedish Academy of Medicine and the Hygienic Associations of Paris and Bordeaux. He was a past president of the Royal Institute of Public Health, of the Leinster Branch of the British Medical Association, and of the Irish Medical Schools' and Graduates' Association. In 1884 he was elected president of the Royal College of Surgeons of Ireland, and in the same year the honour of knighthood was conferred upon him by Queen Victoria "in recognition of his scientific researches and his efforts to improve the state of public health in Ireland." The distinction of a Companionship of the Bath was bestowed upon him in 1899, and in 1902 he was awarded the Harben gold medal by the Royal Institute of Public Health. The list of works from his pen is long, and includes volumes on the chemistry of agriculture, the chemistry of food and a manual of hygiene, but perhaps his chief works were *The History of the Royal College of Surgeons in Ireland* and *A History of Medicine in Ireland*. Sir Charles Cameron was a man of extraordinary energy and activity, but as he always worked in a most methodical manner he never seemed hurried. He found recreation in a change of occupation, and the holidays he allowed himself were spent chiefly in attending medical and other congresses. He held high office in Irish Freemasonry, and he was the founder of the Corinthian Club, a well-known social club in Dublin. He married in 1862, Lucie, daughter of the late Mr. John Macnamara, a noted Dublin solicitor; she died in 1883, and he is survived by a son and two daughters.

PHINEAS SIMON ABRAHAM, M.D.,

Consulting Dermatologist to the West London Hospital,
Hammersmith.

We have to record with regret the death, on February 23rd, of Dr. Phineas Simon Abraham in his 75th year. He had never quite recovered from the serious illness from which he suffered last year, and had been failing for some weeks before his death. He was born in Jamaica; intending to become a mining engineer, he entered University College, London, and took the B.Sc. degree of the University of London. He attended also the Royal College of Science, Dublin, where he was a royal exhibitor. Entering Trinity College, Dublin, he was first senior moderator in 1871, and gold medalist in natural science and scholar. He received the M.A. with distinction from the University of Dublin, and entered St. Bartholomew's Hospital with a science exhibition and scholarship in 1876. He took the diploma of F.R.C.S.I. in 1880, having in the previous year been appointed curator of the museums of the Royal College of Surgeons, Dublin. In 1885 he returned to London on appointment to be lecturer on physiology and histology at the Westminster Hospital Medical School. Shortly afterwards he was appointed dermatologist to the West London Hospital, and became a lecturer on that subject in the Post-Graduate College there. He was also at one time surgeon to the Hospital for Diseases of the Skin, Blackfriars. He was one of the principal founders of the Royal Academy of Medicine of Ireland and of the Dermatological Society of Great Britain and Ireland. He was president of the West London Medico-Chirurgical Society in 1910-11; he had also been president of the Irish Medical Schools' and Graduates' Association. During his term of office he founded and endowed the triennial gold medal awarded by the West London Medico-Chirurgical Society for distinguished services or for exceptional heroism in the discharge of medical duties. When the annual meeting of the British Medical Association was held in London in 1910 he was president of the Section of Dermatology. He was the author of many articles on dermatological subjects, among others those on leprosy and several other diseases of the skin in Sir Clifford

Allbutt's *System of Medicine*. He took a particular interest in leprosy, was medical secretary of the National Leprosy Fund in 1889, and represented this country at the International Leprosy Conference in Berlin in 1897. He edited also the *Journal of the Leprosy Investigation Committee*. Dr. Abraham, whose genial disposition won him many friends, is survived by his widow and a daughter.

The Services.

R.A.M.C. ROLL OF HONOUR.

THE official Roll of the Officers of the Royal Army Medical Corps who laid down their lives in the great war is now published. The total number of names given is 709, divided as follows:

Old and New Armies.		Territorial Force.	
Major-Generals	1	Colonels	2
Colonels	8	Lieutenant-Colonels	13
Lieutenant-Colonels	17	Majors	16
Majors	25	Captains	77
Captains	360	Lieutenants	5
Lieutenants	185		113
596			

The list includes 4 V.C.s and 23 D.S.O.s. There are also the names of Sir Victor Horsley and Sir Charles Ball, 5 recipients of the C.M.G., and 2 of the O.B.E.

The Officers' Roll, comprising over 40,000 names in all, may be purchased from His Majesty's Stationery Office through any bookseller.

NEW RATES OF PAY FOR R.A.M.C. OFFICERS IN INDIA.

The following revised rates of pay have been approved for officers of the R.A.M.C. in India. The new rates have effect from January 1st, 1920:

	Rs. per Mensm.
Lieutenant	650
Captain	800
Captain, after 5 years' total service	900
Captain, after 10 years' total service	950
Major	1,100
Major, after 15 years' total service	1,250
Major, after 18 years' total service	1,400
Lieut.-Colonel	1,550
Lieut.-Colonel, after 20 years' total service	1,650
Lieut.-Colonel, after 25 years' total service	1,850

Charge allowance for command of a British station hospital and specialist pay under para. 155 (d) iii and iv are admissible in addition.

DEATHS IN THE SERVICES.

COLONEL DAVID ERSKINE HUGHES, Bombay Medical Service (retired), died at Kensington on February 9th, aged 77. He was born on June 21st, 1843, the son of the late George Hughes, Writer to the Signet, Edinburgh; he was educated at Edinburgh, where he graduated M.D. in 1864, also taking the L.R.C.S. Edin. in the same year. He entered the I.M.S. on March 31st, 1866, became colonel on September 15th, 1892, and retired on September 15th, 1897. After sixteen years' military service he was appointed civil surgeon of Belgium in 1882, and eight years later of Poona, the prize station of the Bombay Presidency. On promotion to the administrative grade he was posted as principal medical officer of that office in that part districts, retiring after his five years' tour of office in that part. Lieut.-Colonel George Wardlaw Milne, R.A.M.C., died at Nordrach-on-Dee on February 7th. He was educated at the Universities of Edinburgh and Glasgow, graduating M.B. and Ch.B. in 1901, and M.D. in 1911. He served as a civil surgeon in the South African war, gaining the Queen's medal and subsequently joined the West African Medical Staff as district medical officer in Nigeria; while in Africa he served as surgeon to the Uri-Omonohaa Expedition. He took a temporary commission as lieutenant in the R.A.M.C. on October 12th, 1914, became captain after a year's service, and on December 28th, 1918, was promoted to temporary lieutenant colonel.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a Congregation held on March 3rd the degree of Bachelor of Medicine was conferred on Philip G. Doyne.

UNIVERSITY OF CAMBRIDGE.

At a Congregation held on March 5th the Board of Electors appointed the Sir William Dunn Professorship of Biochemistry as follows: Sir W. J. Pope, Mr. F. P. Blackman, Professor T. B. Wood, Mr. W. B. Hardy, and Professors W. Bayliss, J. N. Langley, J. Stanley Gardiner, and C. J. Martin.

The following medical degrees were conferred:

M.D.—E. J. Bradler.
M.B., B.Ch.—A. G. Sharlock, N. W. Jenkin, H. B. Yates.
M.B.—E. E. Llewellyn.
B.Ch.—F. N. Sidebotham.

UNIVERSITY OF LONDON.

THE following have been recognized as teachers of the University in the subjects and at the institutions indicated:

University College: Dr. G. Anrep (Physiology). *King's College:* Dr. James A. Hewitt (Physiology). *St. Thomas's Hospital Medical School:* Mr. B. C. Maybury, Mr. C. Max Pare, and Mr. W. H. C. Romanis (Surgery). *Guy's Hospital Medical School:* Dr. S. Mitchell (Pharmacology). *London Hospital Medical College:* Dr. C. B. Goulden (Ophthalmology). *Attila Hospital Medical School:* Dr. Eric L. Pearce Gould (Surgery). Dr. W. B. Tuck (Chemistry). *Royal London Ophthalmic Hospital:* Mr. B. T. Lane (Ophthalmology).

The Senate has resolved that in and after July, 1921, the first examination for medical degrees commence on the first Monday in July.

The regulations in the Faculty of Medicine for internal and external students (Red Book, 1920-21, pp. 263-9; Blue Book, September, 1920, p. 251) have been amended by the addition of the words "other than for Branch V" after the words "any candidate for the M.D. degree," and by the deletion of the words "in Branch V (State Medicine) of the thesis . . . written and of the practical portions of the examination."

Particulars regarding a further course of lectures on mental deficiency supplemented by a course of clinical instruction, arranged in co-operation with the Central Association for the Care of the Mentally Defective, to be held from May 23rd to June 4th, can be obtained on application to Miss Evelyn Fox, care of The University Extension Registrar, University of London.

Professor H. R. Kenwood has been appointed the representative of the University at the Congress of the Royal Sanitary Institute to be held at Folkestone in June. Dr. G. Newton Pitt has been reappointed to the Senate by the City and Guilds of London Institute for the period 1921-25. Professor Anne Louise McIlroy, O.B.E., has been admitted to the Faculty of Medicine.

Presentation Day will be held at the Albert Hall on May 5th instead of May 4th as formerly arranged.

Eight Beit fellowships for scientific research, of the annual value of £175, will be awarded in July. Forms of applications (which must be received by April 19th) and information can be obtained by letter only addressed to the Rector, Imperial College, South Kensington, S.W.7.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SCURGEY.—W. A. Bryce, A. R. Crane, I. Z. Khaled, G. G. Rigby, H. W. Roffey.
MEMBERS.—W. A. Bryce, O. G. Fisk, M. Foler, B. W. Roffey, H. W. Swann, I. Solomonoff, M. Tchern.
FORENSIC MEDICINE.—W. A. Bryce, E. C. T. Clouston, O. G. Fisk, M. Foler.
MIDWIFERY.—A. G. L. Brown, R. E. Williams.
* Section I. † Section II.

The Diploma of the Society has been granted to Messrs. Z. Khaled and H. W. Swann.

Medical News.

THE portrait of Sir Anthony Bowlby, by Sir William Jewell, R.A., will be presented to him in the Great Hall of St. Bartholomew's Hospital on Friday next, March 18th, at 3 o'clock. It will then be handed by Sir Anthony Bowlby to Viscount Sandhurst, the Treasurer, who will receive it on behalf of the governors.

WHEN the Prince of Wales attends the presentation ceremony at the University of London on May 5th to receive the honorary degrees of Master of Commerce and Doctor of Science a presentation will be made to him by graduates and teachers. It has been resolved that the presentation shall consist of an illuminated fourteenth-century manuscript containing a narrative in French verse of the life and exploits of Edward, Prince of Wales—the Black Prince. It contains a fine miniature of the Black Prince, with the motto, "Ich Dene." This spelling is of interest, as it shows the original form of the Prince's motto, which is characteristic of the Gelderland dialect, and not the high German form, "Ich Dien," which became customary later. The Principality of Gelderland was at the time linked to this country by a strong alliance. Subscriptions from graduates and teachers, ranging from two guineas to 10s. 6d., and from undergraduates, ranging from 10s. to 2s. 6d., are asked for to defray the cost of purchasing the manuscript; they should be sent to Dr. Walter W. Seton, at the University, South Kensington, S.W.

AN "At Home" was given by the Lady Emmott, J.P., Mrs. Anstruther, and Dr. Christine Murrell at the London (Royal Free Hospital) School of Medicine for Women on March 3rd, when the laboratories and lecture theatres were open to the guests; and short talks on the past, present, and future of the school and hospital were given by Lady Barrett, C.B.E., M.D., M.S., Dr. Louisa Garrett Anderson, C.B.E., Professor Winifred Cullis, O.B.E., and Dr. Dorothy Hare, C.B.E.

PROFESSOR LOUISE McILROY, M.D., who has just been appointed by the Senate of the University of London Director of the Unit of Obstetrics and Gynaecology at the London School of Medicine for Women—the first of its kind organized in London—was present at the afternoon party given by their Majesties at Buckingham Palace on March 3rd.

DURING the celebration of foundation week at University College, London, Sir Francis Younghusband, K.C.S.I., will give the foundation oration before the Union Society on Thursday, March 17th, at 8.30 p.m.

SIR WILLIAM COLLINS has been appointed Chairman, and Sir Thomas Barlow Vice-Chairman, of the Central Council for District Nursing in London.

THE Commission appointed by the National Council for Combating Venereal Diseases and sent out to the Far Eastern Ports under the aegis of the Colonial Office has completed its itinerary and will arrive in England on March 14th. The medical member is Dr. Rupert Hallam of Sheffield.

DR. R. A. LISTER, County Medical Officer for Hampshire, has been appointed a member of the Central Midwives Board on the nomination of the Society of Medical Officers of Health.

AT a meeting of the Illuminating Engineering Society in the house of the Royal Society of Arts, John Street, Adelphi, at 8 p.m. on Thursday, March 17th, there will be a discussion on motor-car headlights.

AT the York Assizes on March 3rd, Leonard Mayland, described as a herbalist, pleaded not guilty before Mr. Commissioner Hugo Young, K.C., to an indictment charging him with performing an illegal operation on a domestic servant on November 24th. The jury found the prisoner guilty and he was sentenced to one year's imprisonment.

Letters, Notes, and Answers.

As, owing to printing difficulties, it is not possible to press earlier than hitherto, it is intended for the current issue to be published on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that A.N. letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *MANAGER*, Westrand, London.

2. FINANCIAL MANAGER (Advertisements, etc.), Westrand, London, 2530, Gerrard.

3. MEDICAL SECRETARY, *Medisecm*, Westrand, London; telephone, 2530, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"J. T." asks for information as to the cause of cramp. What part is played respectively by the circulation, nerves, and muscles.

INCOME TAX.

"RESIDENT MEDICAL OFFICER" receives from his Board a monthly statement in the following terms:

	£	s.	d.
Salary for month	42	18	10
Less deduction for supplies	10	15	8
	32	2	2
Less superannuation	0	17	2
	31	5	0

The "deduction for supplies" represents the value of the board and lodging supplied; he asks whether he is assessable on the gross sum or on the net amount excluding the £10 15s. 8d. in question.

"Our correspondent does not state the terms of his appointment. If he was appointed at a salary of £375 with board and lodging provided, then the value of the latter is not chargeable to tax; if, however, he was appointed at a salary of, say, £500, on condition that he bore the reasonable cost of

320.

Cerebellar Agnesia.

MORRISCH (*Amer. Journ. of Nervous and Mental Disease*, December, 1920) reports two cases of cerebellar agnesia, the disease process in the first being confined entirely to the cerebellum with hesitancy in gait as the only clinical symptom, the actual cerebellar changes in the second case being less extensive but producing greater changes in associated areas, the right olive being atrophied, and symptomatically characterized by a moderate slowness of movements, together with some mental retardation. The cerebellum apparently acts as a relay to the corticopetal system, and, when removed, a re-establishment of new impulses is required, having their origin in the cerebrum. Consequently agnetic conditions are usually well compensated, while lesions occurring in adults rarely show such re-establishment of function. The cerebellum has no initiative function in itself, being subordinate to the cerebrum, and having a complex and combined function made up of component parts arising in various portions of the forebrain. The condition may supervene without being clinically demonstrable, and it is sometimes impossible to determine whether one is dealing with a congenital or an acquired lesion.

321.

Syphilitic Contagion of the Newborn.

LOMHOLT (*Ann. de Derm. et de Syph.*, No. 1, 1921) cites from literature two cases of children being infected by the mother at the time of birth, and records three cases of his own. In all these cases the mothers were infected late in pregnancy, and at the confinement had open infective sores on the pudenda. The chancres in four of the infants were on the scalp, and in the other on the cheek. In all the cases the chancres were multiple—in one case as many as eleven sores were found. To differentiate such cases from hereditary syphilis it is necessary to find the spirochaete in the scrape from the sore on the babe, and that the Wassermann reaction of the babe be negative or weakly positive. Further, the classical symptoms of hereditary syphilis are not present. A history of a recent infection in the mother is obtained—as a rule undetected until the confinement, or even shortly afterwards, when the eruption appears.

322

Observations on Mongolism.

COZZOLINO (*La Pediatria*, January 15th, 1921) gives the following details of 23 cases of mongolian idiocy which he has observed between 1906 and May, 1920; 18 were males and 5 females. The youngest was aged 4 months and the oldest 10 years. All the children with three exceptions were under 2 years and sixteen were under 1 year. Only one showed the presence of mongolian spots, so that Cozzolino does not agree with Pentagna, who regards them as characteristic of mongolian idiocy. The familial occurrence of mongolism was exemplified by one family in which there were two cases. In one case there was congenital heart disease, probably patent interventricular septum, in another slight hypothyroidism, in two micro-melia, confined in one case to the upper limbs and in the other involving all four limbs. The blood pressure, examined with Pachon's instrument in 8 cases, was a little below normal. Dystrophic lesions of the fundus in the form of loss of choroidal pigmentation was found in 15 out of 17 cases examined.

323. Herpes Zoster as the only Sign of Latent Disease.

ARNSTEIN (*Wien. klin. Woch.*, January 13th, 1921) remarks that herpes zoster may be the only obvious sign of otherwise latent disease in the internal organs. He recommends, therefore, that in every case of herpes zoster a careful examination of the thoracic and abdominal organs should be made, as not infrequently in such cases disease of the internal organs may be discovered. He records 8 cases in which herpes zoster was the first indication of disease of the liver or lungs.

324.

Solid Food for Infants.

LOWENBURG (*New York Med. Journ.*, December 19th, 1920, and *La Pediatria*, November, 1920) gives his experience with 128 children from 5 to 12 months old when given solid food in addition to milk. He found it useful in most cases. None of the children except those suffering from severe diarrhoea received solid food exclusively, but they were usually given human or cow's milk in addition. Diarrhoea was treated successfully by the substitution of solid food for milk. Constipation was invariably escaped when green vegetables were given. No child under one year was given meat or fish. The solids chosen were chiefly cereals, potatoes, beans, spinach, carrots, beet, lettuce, and prunes.

408 B

SURGERY.

325.

Dakin's Solution in Surgery.

DE FINE LICHT (*Ugeskrift for Laeger*, January 27th, 1921) has not found Dakin's solution of much value when used as an ordinary antiseptic, whether it was used internally or on compresses. But he was more impressed with its action when it was injected into cavities after puncture and evacuation of the original products of inflammation. Particularly in more or less chronic cases of serous or purulent secretion in closed spaces, when the exciting cause was tuberculosis or gonorrhoea, was aspiration, followed by repeated injections and withdrawals of Dakin's solution, beneficial. The author gives a list of the 100 cases which he has treated in this manner. The results were unsatisfactory in cases of empyema, pyarthrosis of the knee, and articular rheumatism. In practically all the other cases, including 31 of tuberculous abscess, the desired effects were obtained. Discussing technical details, the author notes that injection of the solution at as short an interval as every other day seemed to do more harm than good, and the interval he found most satisfactory was one of about eight days. As a rule, one to three injections were sufficient, and when abscesses were large, he found it convenient to puncture at two places so as to provide adequate irrigation of the diseased surfaces.

326.

Transplantation of Sex Glands.

LYDSTON (*Arch. méd. Belg.*, November, 1920), after claiming priority over Steinach and Voronoff, states that at the present time three distinct elements must be considered in the action of the transplanted gland: (1) The initial dose of the sexual hormone contained in the gland at the time of implantation; (2) the production of the nervous hormone by the interstitial cells of Leydig—the production continues as long as the smallest part of the glandular tissue persists; (3) the process of digestion of the different proteins by the tissue of the organism in which the graft has been made leads to the production of an enzyme which has a remarkably stimulating effect on all the cells of the body. According to Lydston grafts may be obtained from bodies in which death was due to any of the following causes: traumatism, acute poisoning, drowning, asphyxia by gas, or execution by hanging. No glands should be used for transplantation when death has not been instantaneous. A survival of even a few hours is sufficient to render a gland useless. A gland should never be employed for transplantation when the subject from whom it is taken has had even the slightest rise of temperature.

327. The Effect of Injections of Sugar on Anaesthesia.

EXNER (*Wien. klin. Woch.*, January 27th, 1921) tested the effect of intravenous injection of 40 c.cm. of 25 per cent. solution of sugar on anaesthesia in 10 cases, the injection being given about ten hours before the operation. He was induced to undertake this experiment by having observed for several years that diabetics were very readily anaesthetized. Another motive was the well-known fact that women advanced in pregnancy or in labour are generally very easy to anaesthetize, require little anaesthetic, and hardly suffer at all from unpleasant after-effects. Exner's 10 cases consisted of 3 laparotomies, 4 operations on the trunk, 2 on the extremities, and one on the brain. Six of the cases were anaesthetized without passing through any stage of excitement and only slight evidence of excitement was observed in the remaining 4, of whom 2 were heavy drinkers, one an epileptic, and one a very nervous individual. The patients came round remarkably quickly and usually without any of the usual retching and vomiting. Exner has not yet had sufficient experience to say definitely how much less anaesthetic a patient requires who has been injected with a solution of sugar, but he is under the impression that much less ether than usual is needed. If this supposition is confirmed, intravenous injection of sugar will be of considerable importance in anaesthesia. No interference with the healing of the wound attributable to the injection of sugar was observed.

328.

Brain Abscess following Wounds.

LEFORT (*Thèse de Paris*, 1920) deals with abscess of the brain following wounds. He states that abscess occurs in 3.11 per cent. of cranial injuries generally, in 24 per cent. of infected wounds of the head. Only the superficial abscesses are easily diagnosed; deep abscesses may remain latent for several months and end by opening into the lateral ventricle. Foreign bodies are the usual exciting cause, often giving a positive culture after months of sojourn in the brain. The chief symptoms of the development of an

abscess are: headache, vomiting, slowing of the pulse, epileptiform crises. The bacteriology of the pus found is important in prognosis, staphylococcus being favourable, streptococcus much more serious. Lefort believes in the importance of auto-vaccination, which appears to have reduced the mortality in Villandre's clinic from 50 to 25 per cent.

329. Artificial Pneumothorax in Fractured Ribs.

SORESI (*Journ. Amer. Med. Assoc.*, February 5th, 1921) suggests the use of artificial pneumothorax in the treatment of fractured ribs. If there is no injury of the lungs or of the pleura, the best manner to prevent expansion of the chest would be by resorting to artificial pneumothorax, which obviously puts the affected thorax at complete rest. In one case in which the sixth, seventh, and eighth ribs were broken, and strapping had not relieved pain, immediately after artificial pneumothorax was effected the patient felt quite comfortable and remained so. Injections of nitrogen were repeated three times.

330. Central Rupture of Liver.

BAUER (*Vierteiljahrsschr. f. gerichtl. Med. öffentl. Sanitäts-wesen*, Bd. 56, Heft 1; *Zentralbl. f. Chir.*, January, 1921) has observed 12 cases of central rupture of the liver, with special reference to the formation of liver abscess. Central rupture is usually the result of compression of the viscus, a more direct blow tending to produce a fissure. Into the traumatized area blood and bile are poured, and may eventually be absorbed, or may, Bauer thinks, subsequently become infected. The common result of a liver tear—outpouring of blood and bile into the peritoneal cavity—does not, of course, occur unless the central injury be accompanied by fissuration elsewhere. The right lobe is more commonly injured than the left. In one case a man fell into a hole and fractured his right fifth rib. For months he complained of local pain and pain on breathing, and held himself so bent that he was ordered a corset. A year later he was suddenly taken ill with rigors and high fever, and was treated for grippe. He died two weeks later, and at necropsy a liver abscess was found. Bauer believes that a traumatic etiology of liver abscess has been much neglected in the past. He thinks the abscess may follow between eleven days and one year after the injury, in rare cases four and ten years later.

331. A Fatal Case of Tonsillar Abscess.

COULET (*Rec. de lar., d'otol., et de rhinol.*, January 31st, 1921) remarks that suppuration in the tonsil or peritonsillar tissue is a frequent event, which occurs in subjects whose tonsils are chronically infected as the result of an increase in the virulence of the organisms or a temporary decline in systemic defences. The condition, however, is generally regarded as unpleasant rather than dangerous. The only fatal complication mentioned in the textbooks is ulceration of the internal carotid or oedema of the glottis. Coulet records a case of tonsillar abscess, probably of influenzal origin, which in four days caused the death of a previously healthy and vigorous young man aged 20 as the result of mediastinal infection. The autopsy showed a large abscess in the right tonsil, cellulitis of the neck, and sero-purulent pleurisy, with marked degeneration of the pericardial sac.

332. Angeliomata of the Larynx.

IRWIN MOORE (*Journ. of Laryng. and Otol.*, January and February, 1921) reviews all recorded angeliomata of the larynx, with special reference to haemorrhage and treatment. In the unoperated cases haemorrhage varied from a small to a severe amount, from single to frequently repeated bleedings. In operated cases severe bleeding occurred in most, but in the cases of thyro-fissure and those treated by radium there was no bleeding; no death was recorded from spontaneous haemorrhage. Of non-operative treatment sulpho-ricinate of phenol and radium proved successful in some cases. If the tumour is not causing serious trouble it is best left alone, but any nasal obstruction or catarrh should be remedied, because of its presence possibly encouraging growth. Of operative measures endolaryngeal removal exposes the patient to the risk of haemorrhage difficult to control, laryngeal spasm, and the entrance of blood into the bronchi. Thyro-fissure is safer, bleeding being practically nil, and recent improvements in technique avoid the risk of opening the larynx. By this means a wide and thorough excision can be carried out, the cut surface of the mucous membrane being afterwards reunited so as to restore its continuity. It is important to differentiate angelioma cavernosum from lympho-angioma, since the latter can more safely be dealt with endolaryngeally without recourse to thyro-fissure.

OBSTETRICS AND GYNAECOLOGY.

333. The Management of Breech Presentation.

PREIFFER (*New York Med. Journ.*, January 29th, 1921) points out that, unless contraindicated by the etiology, breech presentations may be corrected before or early in labour oftener than is commonly supposed if the membranes are unruptured. Under anaesthesia if necessary, with the patient in slight Trendelenburg position, external version should be attempted. After labour has begun and the membranes have ruptured interference is dangerous, unless positive indications arise in the mother or child, since a simple case in which spontaneous delivery might probably occur may be converted thereby into a difficult one endangering the life of the child. When the buttocks reach the floor of the pelvis the soft parts should be widely dilated, either manually or by central episiotomy, in order to minimize the possibility of a considerable tear if the extended arms or after-coming head have to be hastened. Traction is dangerous, and if the efforts of the patient do not advance the breech, compression should be made on the fundus by an assistant. Forceps to the breech are dangerous, and though seldom necessary for the after-coming head, they should be in readiness, as also should be all other necessities for possible emergencies. Caesarean section may occasionally be needed on account of associated anomalies rather than because of the presentation alone.

334. Radium Therapy in Carcinoma of the Uterus.

BETRIN (*La Gyn.*, July-August, 1920) describes the technique of radium therapy for carcinoma of the uterus. The first application of radium for carcinoma of the uterus at the Gynaecological Clinic in Geneva was in 1914, and at that period a very small dose, 50 to 60 mg., was employed for a very short time, and repeated at long intervals. The filtration used was 2 mm. of lead and an envelope of rubber, the whole being placed in the vagina in direct contact with the tumour. At the beginning of 1915 Dr. Chapuis introduced the method of "cross fire" inside and outside the cervix, the dose being raised to 150 mg. From this was gradually evolved the present technique, which the author deals with under three headings: (1) choice of apparatus, (2) preparation of patient, (3) dangers of treatment, and lesions caused by errors of technique. In nearly every case the application was intrauterine and vaginal combined. For the uterus a long curved tube was used, for the vagina the shape of the container varied for each individual case. The total amount of radium was never more than 110 mg.; the duration of the first application was from twenty-four to forty-eight hours, and the subsequent ones twelve to eighteen hours. The apparatus was sterilized by soaking in absolute alcohol. The filtration (which is of very great importance—to stop the alpha and soft beta rays which cause necrosis) used was 1 mm. to 1.5 mm. of lead or brass, inside an envelope of rubber. For the vulva a combined filter of brass and lead is used. Preparation of the patient consists in rendering the vagina and cervix as aseptic as possible. The question of curettage of the growth is still one of controversy, but the author considers that it should not be done. Dangers and lesions due to faults in technique must be noted. The danger of sepsis is a very real one, especially at the first application, but can be eliminated to a great extent by careful preparation of the vagina. The rectum is very sensitive to radium rays, and unless adequate protection is given, pain, tenesmus, diarrhoea, mucous discharge, or even ulceration, may result.

335. Treatment of Uterine Fibroids.

VINEBERG (*New York Med. Record*, January 15th, 1921) advocates myomectomy rather than radium and x rays in the treatment of uterine fibroids in women under 40 years of age, on the ground that the menstrual function is preserved. He quite rightly points out that hysterectomy with conservation of the ovaries is a poor substitute for the normal menstrual function; and the action of x rays and radium definitely produces an artificial menopause. The statistics of W. J. Mayo show 617 abdominal myomectomies with a mortality of 15 per cent., and only 2.5 per cent. required a second operation many years later. In the author's 120 cases there was no mortality, and nine of the patients had subsequent pregnancies. In all cases the author advises opening the cavity of the uterus to exclude the possibility of a submucous fibroid or polypus, and in order to curette the endometrium.

PATHOLOGY.

336. Blood Platelet Enumeration.

GRAM (*Acta Med. Scandinavica*, November 10th, 1920) gives a simple method for the enumeration of the blood platelets, which cannot be detailed here, owing to the fact that the calculations necessitate the use of a table of constants. The particular paper is written in English and may be consulted with advantage by those interested in haematological technique. Gram found from the examination of 122 patients with indifferent diseases that the blood platelets varied between 200,000 and 500,000 per cubic millimetre, the majority being between 300,000 and 450,000. In 27 absolutely healthy men and women the counts varied between 300,000 and 550,000, the majority ranging from 350,000 to 450,000. The number of platelets was found to be diminished in cases of severe pernicious anaemia and leukaemia, and in these patients the symptoms of a haemorrhagic diathesis appeared sometimes when the number of platelets was between 100,000 and 200,000, while a fall below 100,000 generally was accompanied by haemorrhagic symptoms. Several authors have reported low platelet counts in typhoid fever, the lowest counts being obtained in cases showing intestinal haemorrhages. In chronic tuberculosis the development of purpura often occurs simultaneously with a pronounced reduction in the platelet count. Gram reports the condition in 14 cases of uncomplicated influenza and 12 cases of influenzal pneumonia. In the former group the counts showed that at the beginning there was a more or less pronounced fall in the number, which only rarely was strong enough to cause a haemorrhagic diathesis; in the second week of the disease, however, the count rose again and sometimes reached abnormally high values. In the latter group the count fell very low at the commencement and remained low for a week or more, afterwards considerably increasing. The platelet deficit was frequently accompanied by haemorrhagic symptoms, generally epistaxis. There was no parallelism between the variations in white cells and platelets.

337. Colloidal Gold Reaction in General Paralysis.

HAGUENAU (*C. R. Soc. Biologie*, November 6th, 1920) adds his testimony to the value of Lange's colloidal gold reaction in diseases of the central nervous system. Thus, in testing the cerebro-spinal fluid in 30 cases of general paralysis he obtained a typical "paralytic curve" in 28 instances. In the other two cases only a partial flocculation of the gold was obtained, and they might be classed as atypical irregular types. In 6 cases of tabes a typical "tabetic curve" was obtained in 5, but in the remaining case—a tabetic without mental symptoms but with a positive Wassermann reaction—the curve obtained approached more to the "paralytic" type. In 5 cases of syphilitic myelitis or syphilitic hemiplegia showing a positive Wassermann reaction the "paralytic" type of curve was not obtained, nor were reactions of this type encountered in other pathological cerebro-spinal fluids. The author concludes that in the reaction of Lange we have a very valuable means of discriminating between general paralysis and other syphilitic affections of the central nervous system. At a previous séance of the society (October 30th, 1920) the author—who, like most observers, had found difficulty in always preparing stable and useful solutions of gold—reported a method whereby these unaccountable variations of solution could be avoided.

338. Dissemination of *Spirochaeta pallida* in Experimental Syphilis.

EBERSON (*Arch. of Derm. and Syph.*, February, 1921) states that spirochaetes have been isolated from the blood stream of experimentally infected rabbits seven, ten, and thirty days after intratesticular inoculation, at times corresponding to twenty-six, twenty-three, and three days prior to the appearance of any initial lesion. The regional lymphatic glands have been found by Brown and Pearce to contain spirochaetes as early as forty-eight hours after infection, and early invasion of the blood stream was demonstrated by experimental infection with blood obtained from rabbits one week after scrotal inoculation. Thus he establishes the fact that syphilitic infection is not to be regarded as limited to the portal of entry. He deduces from the early finding of spirochaetes in the lymphatic glands that the intermediary stage of the spirochaete does not exist. The spirochaetes can be found in the regional glands before they can be found at the seat of inoculation, but the failure to find them at the seat of entry does not in any way prove a life-cycle for the spirochaete.

339.

Renal Glycosuria.

STROUSE (*Arch. Int. Med.*, December 15th, 1920) considers that the diagnosis of renal glycosuria necessitates four things: (1) glycosuria without hyperglycaemia, (2) glucose excretion almost entirely independent of carbohydrate intake, (3) absence of diabetic symptoms, and (4) no subsequent development of diabetes mellitus. Few cases indeed have been reported in which observation has been sufficiently prolonged to rule out the last two points. Strouse records four cases of renal glycosuria which have been under his observation for from two to eight years; on two of these metabolic studies were conducted. In all, the glycosuria has been persistent, and none has shown symptoms of diabetes mellitus. In one, tests for renal function seven years after onset showed no depression of renal function except in regard to phthalein excretion. The two who have been longest under observation show at the end of four and eight years respectively a utilization of glucose that cannot be considered strictly normal, one at the end of seven years exhibiting a distinctly pathological alimentary hyperglycaemia. This may possibly indicate the beginning of metabolic disturbance.

340. Extraction of Leucocytic Ferments.

TURRO (*C. R. Soc. Biologie*, January 15th, 1921) has obtained strong ferments from leucocytes in the following manner: A fixation abscess was produced in the abdomen of dogs, and the pus cells, having been withdrawn at the most acute period of the process, were washed three times. They were then dehydrated with acetone, filtered off, dried *in vacuo*, and afterwards pulverized. To 20 c.c.m. of sterilized 1 per cent. saline solution, 1 gram of this powder was added and the mixture shaken for fifteen minutes; then 30 to 40 drops of chloroform were added, and the tube, after being corked, was again shaken for fifteen minutes, and put in the incubator at 40° C. Tested from hour to hour the ferment activity of the fluid was found to reach its optimum in twelve hours. After that time the fluid was centrifuged and the extract obtained by decanting was clear and limpid. Turro found that 1 c.c.m. of this extract produced complete hydrolysis of 1 c.c.m. of 1 per cent. glycogen in twenty-four hours. Its bacteriolytic action was tested on anthrax bacilli. The growth from two agar slopes (approximately 244 mg. of fresh culture) was emulsified in 1 c.c.m. of saline, and an equal quantity of the extract was added. At the end of eight hours in the incubator at 40° C. the organisms appeared as a fused amorphous precipitate which was soluble in weak solutions of soda. The author states that the leucocytins obtained from pleural and peritoneal exudates are more active still. The activity of these ferments, thus prepared, decreases rapidly in spite of all precautions, and in three to five days it is quite lost.

341. Causes of Paralysis of the Recurrent Laryngeal Nerve.

SCHMIDT (*Hospitalstidende*, January 12th, 1921) has analysed the causes of paralysis of the recurrent laryngeal nerve in 100 cases observed in two Danish hospitals. Up to the age of 3 years there were only bulbar paralyses, post-infections and traumatic. From 35 to 60 there was a steady rise in the frequency of this paralysis, followed after 60 by an equally steady fall. There were 24 cases of cancer of the oesophagus, among which there were only three women. Diseases of the lungs and mediastinum accounted for 14 cases, equally distributed between the two sexes, and aneurysm of the aorta accounted for 13 (9 males). In several of these cases hoarseness developed before any other symptom indicative of disease. There were 8 cases of heart disease (all women), and, curiously enough, in two of these cases the paralysis was right-sided. Of the remaining 6 left-sided cases 3 were associated with mitral stenosis. All the 9 cases of tumour of the neck were right-sided. This finding the author explains by a reference to the course of the recurrent nerve in the neck being more superficial and exposed on the right than on the left side. When the paralysis was associated with goitre (9 cases) it was anticipated that the disease would in most cases prove to be malignant; but in reality this was the case only in 3 of the 9. The group of 6 post-infectious cases was very mixed, including as it did typhoid fever, influenza, diphtheria, and rheumatism. Among the bulbar and pseudo-bulbar cases (7) were 3 with syringomyelia. The rest of the 100 cases were made up by a few obscure cases and pathological curiosities. In about 60 cases the cause of the paralysis was situated below the upper aperture of the thorax, in 45 the cause was carcinoma or sarcoma, and in about 70 the disease was fatal.

A British Medical Association Lecture ON SOME RECENT ADVANCES IN THE PHYSIOLOGY OF RESPIRATION, RENAL SECRETION, AND CIRCULATION.*

BY
J. S. HALDANE, M.D., F.R.S.,
OXFORD.

In this lecture I shall endeavour to summarize the results of a number of recent investigations, with most of which I have been closely associated, on respiration, renal excretion, and circulation, and to point out, as far as I am able, their significance in helping us to understand the symptoms of disease and the real characters of that marvellous living body with which our profession has to deal. I will begin with respiration, as it was from the side of respiration that I myself, in conjunction with Professor Lorrain Smith, Professor Pembrey, Dr. Priestley, Professor Boycott, Dr. Douglas, and others who worked along with me, approached the subjects of this lecture.

REGULATION OF CO₂ PRESSURE IN ARTERIAL BLOOD.

The rate, depth, and regularity of breathing vary greatly at different times. A graphic record of my breathing while I am giving this lecture would, for instance, present an apparent picture of hopeless irregularity in every direction. If, however, we collect the expired air minute by minute we find that the samples obtained do not vary very much in composition. This suggests underlying regulation; and in order to test this more closely Priestley and I, about eighteen years ago, investigated the air present in the lung alveoli, of which we found that a sample can easily be obtained by catching the last parts of the air expired in a deep expiration. This investigation showed that whether the breathing was rapid or slow, provided only that there was no voluntary interference with its depth, the mean percentage of CO₂ in the alveolar air was maintained extraordinarily steady—far more steady than in the expired air, which is, of course, a variable mixture of the alveolar air with air contained in the air passages at the beginning of expiration.

Addition of moderate amounts of CO₂ to the inspired air, or moderate increases, owing to muscular exertion, of the amount of CO₂ produced in the body, hardly altered the alveolar CO₂ percentage except momentarily. The breathing was simply increased sufficiently to keep the alveolar CO₂ percentage almost exactly the same. Nor did great increases or moderate diminutions in the oxygen percentage of the inspired air alter the CO₂ percentage. By varying the barometric pressure we showed also that it is the partial pressure or concentration of CO₂ in a given volume of air that is kept so constant. At a barometric pressure of two atmospheres, for instance, the percentage of CO₂ which is maintained in the alveolar air is only half that at one atmosphere; but this means that the partial pressure or concentration of CO₂ is the same.

Now the arterial blood leaving the lungs is saturated with CO₂ at the same partial pressure as exists in the alveolar air; and this arterial blood in its turn saturates the respiratory centre at a similar partial pressure, and by so doing stimulates it to activity. The latter saturation, however, takes a little time, since the capacity of the body liquids for holding CO₂ in combination and simple solution is relatively large. The breathing, therefore, responds gradually and smoothly to any change in the alveolar CO₂ pressure, just as if the respiratory governor was associated with a fly-wheel; and at the same time the vagus reflex which governs the depth of breathing is accurately adjusted so that depth and frequency harmonize with one another. The response is extremely delicate. We found that in most persons there is about 5.6 per cent. of CO₂ in the alveolar air. If, by adding sufficient CO₂ to the inspired air, this percentage was raised by 0.2, the breathing during rest was doubled. If, on the other hand, the mean percentage was lowered by 0.2 by voluntary forced breathing, natural breathing ceased for the time, a temporary apnoea being produced.

* Delivered before the Edinburgh Branch of the British Medical Association, March 4th, 1921.

Calculation shows that the corresponding increase or diminution in the free CO₂ contained in the arterial blood was only two parts by weight in a million of blood. This at once affords an idea of the astounding delicacy of physiological regulation. Physiology is an exact quantitative science, and for the purpose of these investigations I had to improve the analysis. But what we are really concerned with is the accuracy of maintenance and this is something very different from what the physicist or chemist is engaged in measuring.

REGULATION OF THE REACTION OF ARTERIAL BLOOD.

Now, when carbon dioxide goes into solution in water it acts as an acid, though a very weak or feeble ionized one. Hence its old name, carbonic acid. Since an investigation by Walter, from Schmiedeberg's laboratory, in 1877, it has been known that in poisoning by dilute acids the breathing is greatly increased, and that accompanying the increased breathing there is greatly increased excretion of ammonia in the urine. It appeared, also, that the increased formation of ammonia in the body was a compensatory process, tending to neutralize the acid. It was the presence of a great excess of ammonia in the urine in diabetic coma that caused von Jaksch to suspect that diabetic coma is a state of acid poisoning or acidosis, and so led to the discovery that aceto-acetic and oxybutyric acids are formed within the body in large amounts in diabetic coma. Shortly after Priestley and I published our work on the alveolar air Pembrey and Beddard found that in diabetic coma the alveolar CO₂ percentage falls to less than a third of normal, but returns towards normal when the symptoms are relieved by sodium bicarbonate. This and various other pieces of evidence led us to conclude that it is probably as an acid, and in conjunction with other acids, that CO₂ acts in the regulation of breathing. But this theory was first established on a quantitative basis by the investigations of Hasselbalch of Copenhagen. He found that by taking an alkali-forming or acid-forming diet he could alter distinctly the percentage of CO₂ to which the alveolar air is regulated during rest, but that the alteration was just such as to keep the reaction or hydrogen ion concentration of the arterial blood steady in so far as the available physical and chemical methods enable us to estimate the steadiness. Putting together Hasselbalch's results and our own, we were able to conclude that the reaction of the blood is regulated with a delicacy which is almost inconceivable, and which can only be followed very roughly by existing physical and chemical methods, though much more closely by the observation and interpretation of symptoms—by "diagnosis." Every normal response of the breathing to increased muscular exertion or other causes leading to increase in alveolar CO₂ percentage betokens a temporary acidosis or diminution in the blood's alkalinity. Calculation shows that a deficiency of one part by weight of ionized hydrogen in about one million million parts of blood suspends completely the activity of the respiratory centre.

Let us glance very shortly at the means by which the blood reaction is regulated. The first means is by regulation of the breathing so as to vary the amount of carbonic acid in the arterial blood. This process of regulation acts very rapidly, but, of course, cannot in the long run deal with the non-volatile acids in the blood. The temporary acidosis of muscular exertion, or the temporary alkalosis of forced breathing, is rapidly compensated approximately by variations in the breathing. Another interesting form of compensation has quite recently been demonstrated by Dodds.* When food is taken there is a rapid secretion of dilute HCl into the stomach, followed about an hour later by alkaline secretion into the small intestine. The gastric secretion of HCl leaves, of course, a temporary excess of alkali in the blood, and this promptly produces a quite marked compensatory rise in the alveolar CO₂ percentage, followed, about an hour later, by an equally marked fall while the alkaline secretion is being produced. A large dose of sodium bicarbonate will also produce a marked compensatory rise in the alveolar CO₂.

The second means of regulation is by varying the excretion of acid or alkali by the urine. Compared with variations in reaction of the blood, which is always slightly alkaline, the variations in reaction of normal urine are enormous. The acidity of average human urine

is mainly due to the presence in it of acid phosphate, and, as L. J. Henderson showed, large amounts of acid can be excreted as acid phosphate without the urine becoming more than slightly acid. The phosphate acts in this respect as a so-called "buffer" substance. In alkaline urine bicarbonate acts as a chief buffer substance, as was recently shown by Davies, J. B. S. Haldane, and Kennaway;³ and in the compensatory excretion of alkaline urine which occurs when a large dose of an alkaline substance is taken, or when forced breathing is continued for some time, very large amounts of bicarbonate are contained in the urine, so that it effervesces on addition of acid. They found also that when a man breathes air containing a good deal of CO_2 the urine becomes very acid and the ammonia in it increases. The same thing, as was recently shown in Professor Meakins's wards, occurs in asthma, since the obstructed breathing causes a rise in the alveolar CO_2 percentage.

The third regulation is by varying the amount of ammonia in the blood; and this form of regulation is seen in all cases, so far as is known, where excretion of ammonia by the kidneys is occurring normally. When dilute acids are administered, even in large doses, to men or carnivorous animals, the compensation by increased formation of ammonia and increased excretion of acid is so perfect that compensation by increase of the breathing is difficult to demonstrate; hence the most prominent ordinary symptom of acidosis is lacking. It was recently shown by J. B. S. Haldane, however, that very marked symptoms of acidosis, with great increase of the breathing, can be produced by considerable doses of a quite neutral salt, ammonium chloride.⁴ The increased percentage of ammonia in the blood brings about reversal of the ordinary reaction by which, if the blood is insufficiently alkaline, ammonia is produced in the body at the expense of urea. As a result some of the ammonia of the ammonium chloride is converted into urea, leaving behind hydrochloric acid. The kidneys alone cannot deal with this acid at all completely, and soon the stock of phosphate which they require for excreting acid begins to run short. The respiratory centre is then called upon to redress the balance, and marked respiratory symptoms of acidosis are produced. This acidosis is relieved by administration of perfectly neutral sodium phosphate, which enables the kidneys to excrete much more acid. These experiments throw new light on renal acidosis, which may evidently be due partly to paralysis or impairment in the power of secreting acid urine and partly to impairment in the power of excreting ammonia, with consequent paralysis of the power of neutralizing acid with ammonia. If the diet is an acid-forming one, or if no food is taken, so that the body is living on its own tissues, there must, when the kidneys are disabled, be a tendency towards acidosis, with the well-known respiratory symptoms so often seen in Bright's disease.

REGULATION OF OXYGEN PRESSURE IN ARTERIAL BLOOD.

Respiration has another function to perform besides regulating the reaction of the body: it regulates the concentration of free oxygen. Recent investigations have tended to show more and more clearly that this regulation is no less exact than that of the reaction, and is of still more immediate importance. Under ordinary conditions regulation of the alveolar CO_2 percentage regulates also the alveolar oxygen percentage. But if under exceptional conditions the alveolar oxygen percentage or partial pressure falls abnormally, as when air poor in oxygen, or at a low atmospheric pressure, is respired, the breathing is increased. Evidently, however, the increased breathing will rapidly reduce the partial pressure of CO_2 in the blood, and this will in its turn reduce the breathing and so mask the respiratory effects of the want of oxygen. Want of oxygen, when produced gradually, has thus comparatively little effect on the breathing. We see this in the symptoms produced in airmen at very low atmospheric pressure, in carbon monoxide poisoning, and in gradual sinking from anoxaemia in phosgene poisoning, pneumonia, and various other clinical conditions. There is no marked struggle for breath. If, on the other hand, deficiency of oxygen in the arterial blood is produced so rapidly that there is not time for CO_2 to be washed out of the respiratory centre, the effects on the breathing may be very striking. Pembrey was the first to show that Cheyne-Stokes

breathing in a patient can be abolished by the administration of oxygen. Douglas and I then found that it can be produced in normal persons by conditions which permit of the comparatively rapid production of anoxaemia, followed by comparatively rapid relief. The respiratory centre is responding to the stimulus of want of oxygen; but as there is hardly any storage of free oxygen in the tissues, the fly-wheel action which exists when CO_2 is the stimulus no longer comes into play, and the respiratory centre "hunts," like an engine with a delicate governor but no fly-wheel. Cheyne-Stokes breathing is always a symptom of want of oxygen.

Since want of oxygen increases the breathing, it lowers abnormally the amount of free carbonic acid in the blood, and thus tends to produce a condition of alkalosis. This was shown recently in experiments at low atmospheric pressure in a steel chamber by Kellas, Kennaway, and myself.⁵ The urine became much less acid and the ammonia in it was greatly diminished. This implied that the alkali available in the body for combination with CO_2 , or so-called "alkaline reserve," was being diminished in compensation for the deficiency in CO_2 . The diminution in the "alkaline reserve" of the blood had previously been noticed, and had been attributed by myself and others to the development of an acidosis calculated to increase the breathing and thus relieve the want of oxygen. In reality there was no acidosis, but only the partial compensation by the kidneys and liver of a respiratory alkalosis. Yandell Henderson and Haggard had meanwhile made some striking experiments in which they showed that during forced artificial respiration, which produces a condition of extreme alkalosis, there occurs a great and rapid compensatory fall in the "alkaline reserve" of the blood, while during exposure to a very high percentage of CO_2 there occurs, conversely, a rapid compensatory rise in the "alkaline reserve."⁶ Diminished available alkali or "alkaline reserve" may thus be a sign of either alkalosis or acidosis. To interpret its actual meaning one must take into consideration all the physiological symptoms and conditions. Much confusion has arisen in recent medical and physiological literature through failure to interpret rightly a diminution in the so-called "alkaline reserve" of the blood. Diminution in "alkaline reserve" of the blood was quite wrongly identified with acidosis.

To understand physiological deficiency of oxygen or anoxaemia we must bear in mind that anoxaemia has no necessary connexion with the amount of oxygen which the blood is capable of liberating from its haemoglobin. What matters is the amount of free oxygen not combined with haemoglobin—in other words, the partial pressure of oxygen. The arterial blood of an anaemic patient, for instance, with only 40 per cent. of the normal haemoglobin, may be capable of liberating only half as much oxygen as the blood of a normal person who has been suddenly transported to a very high altitude, or who is suffering from dangerous want of oxygen during pneumonia. But the anaemic patient will probably have just as much free oxygen as usual in his arterial blood, and will thus, by bringing into play the circulatory regulation to which I shall presently refer, escape completely from anoxaemia during rest; while in the other cases the free oxygen in the arterial blood may be so seriously reduced that no circulatory compensation is possible and life is endangered.

The symptoms produced by even a comparatively slight amount of arterial anoxaemia are very serious. We can study them in their simplest form in mountain sickness. The extreme depression, nausea, headache, etc., are very striking. Accompanying these symptoms are slight cyanosis, Cheyne-Stokes breathing, and orthopnoea. Most attacks of mountain sickness as ordinarily met with in mountaineers can be recovered from without changing the altitude, since the body by increased active secretion of oxygen inwards, by compensation of the alkalosis, and by other means, ultimately triumphs over the disturbing conditions. But if the rarefaction of the air is too great the picture is a very different one: the central nervous system—in particular the respiratory centre—gradually fails; and death occurs gradually and quietly. A vicious circle has been produced and is never broken.

By accurate determinations of the percentage saturation of the haemoglobin in arterial blood, combined with close observation of symptoms and the effects of continuous addition of oxygen to the inspired air, Professor Meakins has recently thrown quite new light on

the pathology and treatment of pneumonia and other respiratory and circulatory affections? A continued deficiency of even one part by weight of free oxygen in a million of the blood present in capillaries may be very dangerous.

Anoxaemia may be caused in several different ways. Of these the simplest is that in which the concentration or partial pressure of oxygen in the alveolar air is insufficient to saturate the haemoglobin. This is the case in stagnant air or air very poor in oxygen. Another cause is thickening or clogging of the lung epithelium by exudation, so that oxygen cannot pass through it into the blood as readily as usual. A typical example of this is phosgene poisoning, and in such cases striking improvement is brought about by adding oxygen continuously to the inspired air so as to raise the diffusion pressure of the alveolar oxygen. Another, and probably much more important cause clinically, was discovered by Meakins, Priestley, and myself during the war.⁸ This is irregular distribution of air in the lung alveoli, owing either to shallow breathing or to irregular obstruction of bronchi. The consequence of this is that some alveoli are ventilated to an abnormal extent, while others are very imperfectly ventilated. Now the increased ventilation will remove a correspondingly increased proportion of CO₂ from the blood, but not of O₂, for the blood's charge of oxygen is nearly saturated. The diminished ventilation will correspondingly diminish not only the removal of CO₂ but also the absorption of oxygen. The net result is that the mixed arterial blood becomes insufficiently saturated with oxygen although its charge of CO₂ is no greater than normal. Symptoms of anoxaemia are thus produced. We found that in various forms of neurasthenia or exhaustion affecting the bulbar centres—a very common clinical condition—the depth of breathing becomes reflexly restricted with production of anoxaemia, which in acute attacks may be very severe, particularly in the recumbent position. The exaggeration of this condition in the recumbent position explains the common symptom orthopnoea. This anoxaemia can be identified clearly by the action of oxygen administration. The anoxaemia of pneumonia, bronchitis, emphysema, and ordinary cardiac cases appears to be mainly due to this irregular distribution of air in the lungs, and this accounts for the striking effects of continuous oxygen administration. It might at first sight seem that in ordinary lobar pneumonia, where the greater part of the lungs may be consolidated, arterial anoxaemia must result from a large amount of venous blood passing the lungs without being oxygenated. In reality the circulation in the consolidated parts is almost entirely blocked, as is strikingly shown in x-ray photographs prepared for Professor Meakins of injected lungs in pneumonia, and also by the fact that the arterial anoxaemia and accompanying symptoms disappear with oxygen administration, or as soon as the rapid shallow breathing ceases on the occurrence of the crisis, though the consolidation remains.

Beyond calling attention to the great interest and importance of the recent Edinburgh work, I shall not attempt to go into details on the subject of anoxaemia, particularly as I did so in a somewhat recent lecture published in the *BRITISH MEDICAL JOURNAL*.⁹ I must also pass over those wonderfully beautiful processes by which the haemoglobin of the red corpuscles assists in regulating both the concentration of free oxygen and the reaction of the blood in the capillaries.

RENAL EXCRETION.

I shall now pass to the subject of renal excretion. The renal secretory structures consist essentially of the glomeruli, first part of the convoluted tubules, straight tubules, second part of the convoluted tubules, and collecting tubules. What happens in each of these parts I shall not attempt to discuss. The parts played in them by filtration, active excretion, and active re-absorption are still obscure. What I wish to speak of is the physiology of renal excretion as a whole; and recent investigation has shown that the kidneys, just like the lungs, regulate the composition of the blood, and indirectly of the whole body, with a delicacy of which in former times there was hardly even a suspicion. I have already referred to the extreme delicacy with which the kidneys help to regulate

the reaction of the blood; but this is no isolated phenomenon.

REGULATION OF DIFFUSION PRESSURE OF WATER IN THE BLOOD.

The main constituent of the blood is water. If we drink water by itself when the body is already fully supplied with water, the result is that the water is promptly excreted by the kidneys. If a very large quantity of water is drunk the diuresis is correspondingly great, and the urine excreted is almost pure water, since hardly any more sodium chloride, urea, and other constituents of the blood are excreted than would be normally. Priestley and I carefully observed the concentration of the blood during profuse water diuresis, but could detect no diminution in its haemoglobin percentage.¹⁰ It is thus evident that if there is any blood dilution due to the water, it is extremely small. By the extremely delicate electrical conductivity method, however, Priestley was able to detect a slight diminution in the concentration of salts, with a return to normal as the diuresis ceased. The slight diminution was, perhaps, partly due to passage of salts outwardly from the blood into the pure water contained at first in the gut. This would have the effect of slightly increasing the diffusion pressure of water in the blood, or, to use what seems to me a wrong, though still customary, expression, of slightly diminishing the osmotic pressure of the blood. Dr. E. F. Adolph has recently investigated in my laboratory the regulation of the normal water content of the body.¹¹ By water-starvation it is possible to reduce by several pounds the body weight, in spite of resistance to this by diminished excretion of urine. When water is again taken freely the body weight simply goes up to its normal amount, and when this point is reached any further water taken is promptly excreted. By various other experiments with diuretic substances he has shown how persistently and accurately the water-content of the body is regulated by the kidneys during health.

REGULATION OF DIFFUSION PRESSURES OF SOLIDS IN THE BLOOD.

When we turn to the solids excreted by the kidneys we find a similar exact regulation. As Anibaud has pointed out, however, we must distinguish between substances of which, as in the case of water, there is a normal threshold concentration or diffusion pressure in the blood, and substances which, so far as is yet known, are actively excreted even to their lowest concentrations in the blood. Urea, ammonia, and sulphates, for instance, seem to have either no threshold concentrations or very low ones. The blood and tissues contain usually about 0.025 per cent. of urea and 0.0005 per cent. of ammonia—about an eightieth of the percentage commonly concentrated into the urine. On the other hand, there are sharply defined normal thresholds for sodium chloride and sugar. When the percentage in the blood rises above these thresholds, even to a very minute extent, excretion by the kidneys begins, and becomes more and more vigorous the more the thresholds are exceeded; but when the percentage falls to the thresholds, excretion practically ceases. Similarly there is an amazingly sharp threshold of blood alkalinity. Below this threshold acid urine is excreted, while above it the urine is alkaline. The dividing line is defined with a delicacy of which physiologists, misled by gross mechanistic conceptions of physiological activity and by the absence of accurate measurements, had no clear conception till quite recently.

When we know what the normal kidney is continuously doing for the body we have the necessary groundwork for discovering what is happening in disease. A kidney disabled for the time by inflammation cannot perform the excretory functions just described, or can only do so feebly. The kidney may, for instance, be lamed as regards regulation of blood alkalinity or excretion of ammonia, with the result that if the diet is an average one, or if no food is taken, acidosis is produced. If the excretion of salts is interfered with and the diet is normally rich in salts, they accumulate in the blood. One result is that the diffusion pressure of water in the body is diminished; hence water, even though the kidneys are still capable of passing it, is retained in the body and dropsy is produced. Another possible result is poisoning due to abnormal proportions of salts or other substances. When we have

"diagnosed" exactly what is happening—we can adopt dietetic and other measures to control the evil and tide the patient over till normal processes of recovery have had time to develop. Even though we do not yet know how each part of a normal or disabled kidney is acting, yet, if we can diagnose from the symptoms how the kidney as a whole is failing, we have sufficient data for prescribing rational treatment.

CIRCULATORY REGULATION OF BLOOD COMPOSITION.

Let me now turn to the physiology of the circulation. All that I have already said shows how exactly the composition of the arterial blood is regulated. But in passing round the circulation the composition and temperature of the blood are constantly and very rapidly altering. We may be certain, however, that it is not for nothing that the composition and temperature of the arterial blood are kept so astoundingly steady as they are.

The most rapid and prominent alteration is in the blood's charge of O_2 and CO_2 ; and the change in the colour of the blood as it loses oxygen makes this alteration grossly evident to our vision. I wish now to refer to recent evidence that not only is the composition of the arterial blood accurately regulated, but also the composition of the blood as it leaves the capillaries in the different parts of the body. Physiologists have devoted far too much attention to study of the mere physics of the circulation. What is more important is its physiology—its organic regulation.

Dr. Douglas and I have been engaged for some years in investigations—greatly delayed by the war and its aftermath—on the gases of the mixed venous blood returning to the heart in man.¹² We discovered a method of investigating these gases by determining the composition of the air with which they are in equilibrium when the lungs are artificially filled with such air. The first result of these observations was to show that during complete rest the mixed venous blood is not only very steady as regards its gas content, but is considerably less venous than has hitherto been supposed. The general circulation rate during rest is faster than was formerly calculated. In my own case, for instance, a volume of blood equal to that in the whole body passes through the heart about every thirty-five seconds—about eight litres, or 1.8 gallons, of blood passing in one minute. During muscular exertion the rate is further increased, but in Dr. Douglas and myself only about in proportion to the increase of pulse rate, although the rate of oxygen consumption may be increased eight or ten times. The mixed venous blood becomes, however, far more venous than during rest, so that it may have lost about two-thirds of its oxygen content. From this fact we cannot conclude, however, that in any part of the body the blood becomes at all markedly more venous during work than during rest. It was found many years ago by Leonard Hill, in experiments on animals, that the venous blood from muscles, whether during rest or during work, has lost by far the greater part of its oxygen, but that the venous blood from the brain has lost very little. The oxygen supply to the brain is thus far more free than that to a muscle. During work the blood supply to a muscle must be enormously increased—probably twenty or thirty times—in order to meet the increased consumption of oxygen. Consequently the mixed venous blood contains a far larger proportion of this very venous blood, and this accounts for its being more venous.

A flood of new light has recently been thrown on the regulation of local circulation by the investigations of Krogh of Copenhagen.¹³ It had been shown many years ago by Roy and your president, Dr. Graham Brown, that the capillary walls are contractile. Krogh found by microscopical observation of transparent muscular tissues that during rest nearly all of the capillaries are tightly closed, so that no blood, or even plasma, can pass through them. During activity, however, these closed capillaries relax and become permeable to blood, so that an enormously increased oxygen supply is at once rendered available. We can thus understand how, in spite of the increased oxygen consumption of a working muscle, its oxygen requirements can be met without appreciable lowering of the concentration of free oxygen, or alteration of the reaction, in the local blood supply.

The constancy of the oxygen and CO_2 content of the mixed venous blood during rest has the same significance as the similar constancy of the arterial blood. What it

points to is that the composition of the venous blood leaving particular organs is regulated just as much as that of the arterial blood. In other words, the blood flow is so regulated as to ensure this constancy. In the brain the required concentration of free oxygen is evidently very high, and this accounts for the fact that any failure, even slight, in the aeration of the arterial blood has such serious consequences in producing nervous symptoms. It accounts, also, for the striking anatomical fact that the blood vessels supplying the brain are very large, even though the white matter of the brain may have a relatively low oxygen consumption.

I have not time to discuss in detail how the bulbar centres which regulate the action of the heart and the calibre of the larger blood vessels, as well as the breathing, react directly or indirectly in response to the chemical or thermal stimuli which consist in slight variations in the gaseous and other composition, or temperature, of the blood. Nor have I time to discuss how local blood supply responds to the local chemical stimuli through which organic regulation of the blood composition in every part of the body is maintained. I should like, however, to refer, in conclusion, to certain broad principles which seem to emerge very clearly in connexion with the recent advances which I have been describing.

SIGNIFICANCE OF PHYSIOLOGICAL REGULATION.

First and foremost it seems evident that physiological regulation is not only something very real, but is also extremely delicate. It is only by exact quantitative observations that we can estimate the delicacy of regulation; but symptoms, if we interpret them rightly, give us an extremely sharp index of failure in normal regulation. I need hardly, however, speak to such an assembly as this of the paramount importance of the close observation and right interpretation of symptoms. Regulation to a normal during health implies that the living body actively maintains a normal of structure and activity in spite of ever-changing conditions of environment. From side to side of this normal the living body is constantly oscillating as the result of disturbance in the environment, and constantly tending to return as near as may be to the normal in spite of the disturbance. We can distinguish ordinary physiological disturbances, which the body can easily overcome, from the more serious disturbances which require medical or surgical treatment to assist the return to normal or something approximating to it; but apart from the fundamental assumption that it is, to use the old expression of Hippocrates, the "nature" of a living organism to maintain a normal, and to return towards it in spite of disturbance, physiology and medicine seem to me to be a mere chaos of unconnected empirical observations. It is the reality of organic regulation, and the necessity for the guiding conception of organic regulation, that stand out in the results of the investigations, which I have tried to summarize. The aim of physiology, and of every branch of biology, is, as it seems to me, to render clear by experiment and observation what the normal activities and structure of a living organism are, what the deviations from them really consist in, and how the normal tends to be maintained or re-established in face of disturbance.

BIOLOGY NOT BIOPHYSICS AND BIOCHEMISTRY.

Another ideal for biology is to search out the mechanism—the physical and chemical causes—of all biological phenomena. This ideal aims at superseding the Hippocratic conception that it is the "nature" of a living organism to maintain a normal, and it represents biology as simply "biophysics" and "biochemistry." To this conception of biology the objection is that it does not enable us to understand and predict the facts. Why does the respiratory centre fail to react to increase in hydrogen ion concentration until a certain threshold value is reached, and yet react so vigorously as soon as this threshold value is exceeded to the minutest extent? Why do renal excretion and circulation behave in a similar manner? Why do reflexes adapt themselves to varying conditions, as in the case of the respiratory reflexes? Why does the body tend obstinately to maintain in every aspect of its structure and activity a certain normal? And why, from generation to generation, is this structure and activity so accurately reproduced? To these questions the mechanistic conception of life affords no answer. Yet

the phenomena which raise them are the characteristic phenomena of life. It is because of the necessity in any science of having working conceptions which correspond to observation that I must claim for biology her own working conception—that of the living organism as such. This was essentially the claim which Hippocrates was the first to put forward; and to me he appears as the father, not only of scientific medicine, but also of biology in general.

THE GREEK SCIENTIFIC TRADITION IN MEDICINE AND BIOLOGY.

It seems to me that the progress of biological investigation is and has been steadily in the direction of consolidating the Greek scientific conception which has been so closely associated with the development of medicine. The supposed mechanism of life has been steadily eluding our mental vision, while knowledge of organic regulation has been equally steadily advancing, as has been illustrated in this lecture. I have tried elsewhere to show that the mechanistic conception of life is based, not on biological observation, but on metaphysical assumptions for which there is no sound basis.¹ Without going into this controversy, however, I wish to point out that the Greek conception gives us a working hypothesis which knits existing physiological knowledge together in a way that the mechanistic theory is quite incapable of, and which suggests new and fruitful paths of investigation in every direction. It also seems to give us what may be called a working philosophy of practical medicine and surgery. We of the medical profession are not mere chemists and mechanicians. Our business is to understand organic regulation, and where necessary to assist it. We cannot pretend to understand, replace, or repair, a physical and chemical mechanism which is beyond our powers of conception, and which, in my own opinion at least, is simply not there any more than was the traditional black hat in the dark room. What we can do, and do more and more effectively the more we understand of organic regulation and the conditions which disturb it, is to assist in the maintenance or restoration of this regulation.

Is the Nature which we are concerned with nothing but that apparent world of matter and energy which the working conceptions of physics and chemistry present to us? If it is, then organic regulation is only an appearance which will some day be explained in physical and chemical terms. Those who have been carried away by the flood of popular materialism which has been passing over the world in recent times are ready to answer this question in the affirmative and to go back to the search for the black hat in the dark room. Well, I cannot go with them. It seems to me that there are unanswerable reasons for concluding that the black hat is not there, and that the world as interpreted by the physicists and chemists is not the objective or real world, but only an imperfect subjective interpretation of it. The aspect of Nature which Hippocrates saw in the living body, and which a doctor can hardly help seeing in his daily work, is to my mind much nearer to objective reality than the aspect which is depicted by the physical sciences. What I have been trying to show to you this evening is that deeper and truer aspect of Nature which is seen not only in Medicine, but also in every other branch of biological work.

A SECOND volume of *Studies in the History and Method of Science*, edited by Dr. Charles Singer, is about to be issued. The first volume appeared in 1917, with a preface by Sir William Osler. The second volume contains articles by Dr. E. T. Withington, on the Asclepiadae and the priests of Asclepius; by T. J. Cole, on the history of anatomical injections; by T. C. Conybeare, on four Armenian tracts on the structure of the human body; and by Mr. Arthur Platt on Aristotle on the heart. The editor contributes two articles, the one on Greek biology and its relation to the rise of modern biology, and the other on steps leading to the invention of the first optical apparatus.

PHYSIOLOGICAL PRINCIPLES IN MIDWIFERY PRACTICE.

BY

JOHN S. FAIRBAIRN, M.A., B.M., B.Ch.Oxon.,
F.R.C.P., F.R.C.S.

OBSTETRIC PHYSICIAN, ST. THOMAS'S HOSPITAL.

THE reproductive cycle in its widest sense—from one generation to the maturity of the next—has somehow never received adequate attention from the physiologist or taken its proper place in the medical curriculum. From the purely biological aspect the only claim to the continuation of a species rests on its ability to perpetuate itself in the struggle with other species; from the medical standpoint, reproduction is as much an integral part of medicine as digestion, respiration, or the circulation. Owing, however, to the way in which medical practice and knowledge has developed, and not on logical grounds, much of what is included under the heading of the reproductive cycle has been separated off from medicine. Eugenics may be left out of account as too largely a sociological matter, but midwifery, in the modern interpretation of the term—that part of the cycle from conception to the care of the nursing mother and nursing—has been separated by practice: pediatrics and the importance of the developing child and adolescent have only recently been thrust into the foreground by a universal quickening of the consciousness of nations as to the necessity for the care of the rising generation. Perhaps as a result of the loss of its proper place in physiology and medicine the early part of the reproductive cycle—the part that counts most—has been later in acquiring the present-day tendency of medicine to study its problems from the point of view of physiology rather than pathology, and I wish to see what this may mean if applied to that portion of the reproductive cycle I have included under the term “midwifery.”

I will begin by taking as an instance of what greater attention to physiological processes may do, the change in our practice as regards infant feeding, and afterwards try to apply these lessons to the management of the woman in labour. I do this because this change has influenced my own mental attitude towards labour more than anything else, and may have a like influence on others, and also because it forms an illustration of reformation along physiological lines already accomplished, and thus indicates what may be possible in the case of labour.

Formerly our attention was largely directed towards perfecting substitutes for the natural food of the baby, and great success has been obtained in adapting the milk of another mammal, so as to enable the human infant to thrive on food never intended for it. Our textbooks devoted no more than a line or two to breast-feeding. There was a pious statement that it was best for infant and mother; there was a list of contraindications and instructions as to how to disperse the milk when suckling was not carried out, and that was about all; whereas the preparation of substitutes and the modification of cow's milk and other possibilities took up pages, and even chapters, so that there is little wonder that the student, when he had blossomed out into a practitioner, was entirely ignorant of the physiology of lactation and the management of breast-feeding. No attention was given to the causes of failure to suckle and how they might be removed, or to the means of increasing mammary activity when inefficient, or to the investigation of the reasons why the baby did not thrive satisfactorily at the breast. I am indebted to Dr. Truby King—and many others with me—and to what is accomplished at the School of Mothercraft, of which he was Director during his stay in this country, for an entirely fresh idea of the possibilities of breast-feeding in difficult cases.

At any time in the school at Trebovir Road living evidence of what a few years ago would have been thought impossible may be seen in the shape of mothers who have failed in previous confinements, and mothers whose infants have been weaned for six weeks or more, successfully nursing a contented baby. The error was that our energies had been devoted to providing a substitute for the function we did not attempt to control. We were clearly on wrong

* Part of a paper read in opening a discussion at the Sheffield Medico-Chirurgical Society, February 17th, 1921.

lines, for, however successful, such substitutes could never be as good as the real thing. We should rather have studied the function of lactation and how to improve it when defective—precisely what we are now learning to do.

I would apply this lesson to the management of labour in cases of deficient uterine action, for the analogy is a close one. Our attitude up to now has been largely that of perfecting the substitute for the maternal powers—namely, the bawny bigs of the attendant exerted through the midwifery forceps—and, as in the case of artificial feeding, we have attained great success, but also along wrong lines. If there is delay owing to deficient uterine action, the one idea of the attendant is to finish off the labour by instruments, just as the one idea in deficient mammary activity was to be off with the natural feeding and on with the artificial. Suppose, therefore, we adopt the same attitude towards parturition that we have adopted towards lactation, what will it mean?

It will mean a closer study of the normal functioning of the uterus, the factors that hinder it, and of how, by the removal of such factors, the natural powers can be made effective. We will first concentrate on eliminating the indications for the artificial termination of labour and reserve the forceps for those cases in which we fail to secure natural labour. It is no more than following the same line of thought towards management of sluggish uterine action, as towards sluggish intestinal action.

Putting aside cases of complicated labour and those in which some obstructive element is present, and confining our attention to simple delay, there are certain causes which can be readily detected and remedied, such as distension of the bowel or bladder, uterine obliquity, especially that associated with pendulous abdomen, and others, such as over-distension of the uterus and early rupture of the membranes, which may be easily recognized, but not so easily remedied, as there may be other complicating factors. The conditions chiefly contributing to failure of good uterine function in cases of otherwise normal labour may be grouped under the two headings of emotion and fatigue, and I would argue that it is their prevalence, particularly among the more leisured classes, that leads to the frequency of the artificial termination of labour, and I would therefore direct attention chiefly to a consideration of how these conditions can be removed.

Taking the emotional factor to begin with, it is likely to be operative in nervous, highly-strung women, particularly in their first labour. It will be increased by dread of the unknown, by what they have heard of the trials of their acquaintances in childbirth, by the constant suggestion of the necessity of artificial aid, by such circumstances as sympathetic mothers, husbands, and friends, and the concentration of their household on the event in which they, as patients, are playing the principal part. If, as so often happens, the anticipated date is past, they may have had several disturbed nights thinking about, and looking for, the expected pains that are to usher in their time of trial. Perhaps, also, there may be domestic and other worries to add to their mental distress. Thus the frame of mind in which labour begins is often highly unfavourable to physiological parturition, and is then aggravated by the wrong type of nurse and by the arrival of the medical attendant with a bottle of chloroform and a bag of clinking instruments, with their strong suggestion of a speedy ending without further effort.

The other factor, fatigue, requires perhaps even more management, for the uterus of an exhausted woman will not function efficiently. Loss of sleep, want of food, and, most of all, the fatigue that comes of long-continued pain, are among the common causes producing exhaustion.

The practical question is how far we can expect to make labour more natural by our endeavours to remove these causes of uterine inefficiency, and in regard to this I can only give suggestions, for the subject is too wide, and my intention is rather to indicate the lines of approach to the problem than to go into details.

In the first place, the study of the individual patient and an attempt to understand her temperament and attitude of mind towards labour is obviously important. The ante-natal care and observation should not be such as to increase her fears and anxieties, but should rather be directed towards reassuring her and impressing her with the idea that she is a normal woman capable of bearing her child naturally. In the case of a woman in her first pregnancy

some time spent in discussing the course of labour, what is to be expected and what she can do to help herself, will not be wasted, and, should she consider herself above the usual age for a first baby and, as is often the case, have special fears, an endeavour should be made to reassure her. The choice of a nurse, too, is a matter of extreme importance; the ideal nurse is hard to find, but if discovered, is beyond price. The talkative and ignorant creature who scares her patients with stories of what has happened to other unfortunate mothers on whom she has been inflicted, or the nervous woman who is easily worried by any incident she thinks may indicate something abnormal, are especially to be avoided. Lack of confidence and over-anxiety are at once reflected in the patient, and a nervous nurse makes a nervous patient. The quiet, understanding woman who recognizes where her patient requires help, and gives a feeling of strength and confidence, will have many more cases of natural labour than the over-anxious and fussy type.

When it comes to the labour itself the advantage of institution management over home delivery is readily seen, and forms an additional argument to that advanced by Mr. Bonney in his paper on "The continued high maternal mortality of child-bearing," on account of its better provision for surgical technique, in that it avoids also many domestic annoyances and the presence of well-meaning but unneeded relations. In the conduct of the labour the object of the medical attendant should be rather that of supervision, and of a supervision that is kept as much in the background as possible. Satisfied that everything is normal, all that can must be done to suggest that the patient's powers will suffice, and that no active interference will be required. The less he is with the patient the better. But she must not be allowed to become played out. Should she bear pain badly, become restless, and lose self-control, relief must be obtained by means of morphine, or morphine and hyoscine, or other sedative, and to my mind, the great art in the management of labour is the knowledge of how and when to give relief to the exhaustion of the uterine pain. Every practitioner may have his favourite method—twilight sleep, so called, the old-fashioned opium or chloral and bromide—but everyone engaged in midwifery practice must study his patient and by careful observation watch for the indications of fatigue and endeavour to prevent its onset. The morphine hyoscine narcosis has this great merit, that it greatly diminishes the emotional and fatigue effects, and though it may be argued that labour in which the patient is doped with toxic drugs is less physiological than one without drugs terminated by forceps, sedative drugs are too valuable under present conditions to be dismissed in this way. All drugs that have a sedative effect also interfere to some degree with the reflexes and with physiological action, and the problem, as it appears to me at the present time, is to decide how far the obvious disadvantages of their administration compensate for their equally obvious merits.

As a rough generalization I would advocate that preference be given to artificial delivery by the forceps when the failure of the natural powers is only the overcoming of the final obstacle, the muscular resistance at the vulval outlet; and, on the other hand, to place reliance on sedative treatment when deficiency in the expulsive powers is shown when the head is still some distance above the outlet. With increasing knowledge and experience of conducting labour on physiological lines there will gradually come fewer cases of failure to effect the final expulsion.

Returning to the analogy of successful breast-feeding, we cannot but be impressed by the importance of the "atmosphere" of the institution in which it is conducted and think how a like success might be attained in parturition. In the School for Mothercraft, for instance, the anxious mother, distraught by the care of an ailing baby, comes into an atmosphere of assured success with every suggestion of failure removed. The other patients are themselves a factor in her treatment; she hears of more obstinate cases than hers, and sees well-doing infants that were in a worse plight than hers, and the whole ritual impresses her as arranged to spell success. She, in hopes of a cure, is sent for her exercise in the open air with the woman who has been successful beyond her dreams and expatiates thereon. The sisters and nurses, full of confidence in the methods, impart a like confidence to the patients, and half the battle and more is won by the spirit

of the place. It is so striking that one feels that a similar "atmosphere" in the maternity home would also be victory half gained. The patients would be carefully supervised during pregnancy, so that all cases likely to have obstructive or other abnormalities were kept apart, and the place labelled as a home or hostel for natural labour, and not called a hospital. The midwives and nurses, carefully chosen and inspired with the spirit of the place to see their patients through a natural labour, would be on their mettle to make the methods a success, and would provide the proper atmosphere in which all suggestion of failure is abolished. The medical supervision would be kept in the background, and care would only be required to see that the methods were not carried to the extreme of refusing to recognize failure and postponing forceps delivery to the detriment of mother and infant.

A scheme of this sort is merely applying lessons learnt elsewhere in medicine. It is Dr. Hurst's method at the Scale Hayne Hospital for shell shock and war neurasthenia. The man struck dumb comes to be cured into a place where the chattering patient in the next bed was dumber than ever he was, and was miraculously restored to speech, as he will be, and so is the cure wrought.

This brings us to the final consideration as to what the future of medical practice in regard to maternity work will be, and, without wishing to attempt the dangerous art of prophesy, I would indicate merely possible changes. The duty of the doctor will be, much more than in the past, the supervision and "vetting" of pregnant women, and the picking out for special management of cases where trouble is likely. The ordinary cases will more and more be left to the charge of trained midwives, medical attention being required rather for unforeseen complications, for the prevention of fatigue, and for delivery in protracted cases. I suggest that once the primary object of the medical attendant is recognized to be the securing of a normal labour, his attendance in the lying-in room is not essential, and, at any rate, need only be occasional—when summoned by the midwife, or for visits of supervision. This is necessary to avoid the strong suggestion of artificial interference which his attendance means, and because among women delivered by midwives the percentage of instrumental deliveries is low, and the reverse for those attended by doctors. I would hope that every practitioner in family practice would have a list of competent midwives, who would be reserved for the duty of attendance on labour, and not merely employed as monthly nurses, and would carry out his methods in the spirit as well as the letter.

It is perhaps rather much to hope for in this world of erring mortals, but it is something to look forward to, and when one notes the reluctance of medical practitioners to take midwifery cases, and sees advertisements of practices made attractive by the announcement that there is little or no midwifery, and recognizes at the same time the primary importance to the nation of the maternity service, the advantage of securing the best medical supervision without taking up too much time and service in attendance on normal labour seems only possible if most of that attendance be given by trained midwives. This involves rather a shifting of the medical service from the part where least essential to those parts where it is most essential: the observation of pregnancy, the study of the individual characteristics of the woman, and the determination of the best methods of management; supervising her labour merely so far as to be assured of the absence of complications, and deciding what is advisable to maintain good uterine action and to avoid fatigue, and generally being ready to answer the summons of his midwife and to act on her reports; after the labour to give much more attention to the puerperium, to lactation, and the young infant, than has been the case in the past. Doubtless the public will have a big say in any change of method, but hitherto the medical services for maternity work have never been paid for adequately, and their shortcomings are, to my mind, largely ascribable to that fact. The public has expected an expenditure of time and skill for fees that are by no means equivalent, and the tendency of the profession has been to cut the loss by shortening the duration of the labour artificially.

Perhaps these speculations as to the lines on which the maternity service will develop are wide of the mark, but I feel sure that they will tend to approach nearer to physiology, and not away from it.

THE TREATMENT OF SYPHILIS.*

BY

HENRY MACCORMAC, C.B.E., M.D., F.R.C.P.
PHYSICIAN IN CHARGE OF THE SKIN, MIDDLESEX HOSPITAL.

AND

E. L. KENNAWAY, D.M., D.Sc.

CLINICAL PATHOLOGIST, BEAUMONT INSTITUTE OF PATHOLOGY,
MIDDLESEX HOSPITAL.

THE records we publish are the results of some investigations carried out by us in an attempt to gain more definite knowledge of the exact manner in which salvarsan—or one of its substitutes—acts in syphilis. To attain this end we have taken samples of blood before each weekly injection, a method which has afforded us a number of facts from which we have drawn certain conclusions.

It is common knowledge that when salvarsan was first introduced it was thought that one injection would cure syphilis. Further experience soon showed that several injections were required and that mercury should also be given. Such is the position to day, but although potent arsenical drugs have been in common use for ten years, there is no general agreement as to what amounts of these remedies should be employed or over what time the treatment should be continued.

Curiously enough the first patient treated with salvarsan in the skin department of Middlesex Hospital in 1910 was cured by one injection of 0.6 gram of the original preparation, although the form of malignant syphilis from which he suffered had resisted all other remedies. As he was kept under observation for four years the belief in the reality of his cure seems justified. But such a result is unique in our experience. Indeed, considerable amounts of an arsenical compound and mercury may be given and yet failure result. These failures have tended to throw some doubt upon the efficacy of this form of treatment; but one must bear in mind that failure may be due not only to a defect in a remedy, but also to the manner in which an effective remedy is used.

TABLE I.—Cases of Secondary Syphilis.

	Intra- venous N.A.B. (No. of Injec- tions).	Total Amount (Grams).	No. of Mercury Injec- tions, each 1 Grain.	Wassermann Reaction.
No. 63 ...	6	2.7	17	Positive 13 months after end of course.
No. 68 ...	7	3.75	24	Positive 7 months after end of course.
No. 144 ...	12	10.2	13	Positive after 6 months.
No. 164 ...	10	6.0	14	Positive at end of course.
No. 180 ...	6	3.5	21	Positive after 1 year.
No. 32 : Course 1	6	3.4	32	Suspicious at end of course.
Course 2 [*]	6	5.4	29	Two months after this negative; 6 months later positive.

* Directly after Course 1, because of suspicious Wassermann reaction.

In Table I six such cases are shown. It should be noted that all were in the secondary stage—a peculiarly favourable period; that considerable amounts of novarsenobenzol and mercury had been given; and that in every case the Wassermann reaction ultimately became positive. In No. 32 actually two separate courses were undertaken. To save repetition it may be stated here that the arsenical preparation used in all cases reported in this paper was novarsenobenzol Billon (N.A.B.) administered by the intravenous route.

This type of treatment is thus open to criticism—although it is a form commonly followed—and should be replaced by some other. Either larger doses of N.A.B. should be used, or more numerous injections given, or both. These questions received consideration when Dr. Pringle took charge of the department in 1917, and he formulated a scheme which has been adopted. It is as follows: ten intravenous injections of N.A.B. are given at

* An address to the Essex Branch of the British Medical Association on September 23rd, 1920.

Table III is compiled in a manner similar to Table II, but here all the cases represent the secondary stage. As in the previous group two series are included, one where mercury and N.A.B. were combined, and a second where

N.A.B. alone was given. A favourable response to treatment is still found. In three cases 12 injections were given, in one 11, in one 9, in one 8, and in two 7; the remainder received 10 injections. No. 831 is an example of severe and extensive involvement of skin and throat, where the negative reaction appeared after the third injection. Thus in the secondary, as in the primary phase, the clinical manifestations alone furnish no information as to the rate of progress under treatment as judged by the change in the Wassermann reaction.

A more general examination of the reaction shows that a favourable response occurs somewhat earlier in the first series. The actual findings are brought together in Table IV, which indicates that there is some slight advantage in the plan of administering mercury and salvarsan together.

TABLE IV.—Effect of Treatment in Cases of Secondary Syphilis.

In patients who received treatment by Arsenic and Mercury the Wassermann reaction first become negative as follows:

	After 1 injection in	***	***	***	1 case
"	3 injections in	***	***	***	2 cases
"	4 "	"	"	"	2 "
"	5 "	"	"	"	1 case
"	6 "	"	"	"	3 cases
"	7 "	"	"	"	5 "
"	8 "	"	"	"	4 "
"	9 "	"	"	"	1 case
"	10 "	"	"	"	1 "

18

In patients treated by Arsenic only the Wassermann reaction first became negative as follows:

After 4 injections in	1 case
" 5 " " "	" "	" "	1 "
" 6 " " "	" "	" "	1 "
" 7 " " "	" "	" "	3 cases
" 8 " " "	" "	" "	1 case
" 9 " " "	" "	" "	1 "
" 11 " " "	" "	" "	2 cases

10

As compared with primary cases the negative reaction appears more slowly, but is still obtained. In Case No. 854 the Wassermann reaction was found to be negative at first, although a well-marked skin eruption was present. One other case, No. 829, demands comment. This is an example of a second infection occurring while the patient was still under treatment for a previous infection. He first came under our observation with a chancre on the abdomen and his progress during the series of N.A.B. injections is indicated in the table. Subsequent treatment with mercury was continued for one year when he again developed a chancre, this time on the penis. That this was not a relapse is shown by the following facts: The first chancre was upon the abdomen, the second on the penis, and there was a history of exposure four weeks prior to its appearance. Abundant spirochaetes were present in the second chancre. The Wassermann reaction was negative at periods of six and nine months after the first infection. It is interesting to observe that this man had remained under treatment up to the time of his second attack, and thus acquired syphilis while saturated with mercury, and that his Wassermann reaction became positive shortly after the appearance of the second chancre. It is impossible to say whether he would have developed secondary manifestations or not, as he was put under further treatment with N.A.B. immediately.

From the facts appearing in Table III certain deductions may be drawn. It is evident that an "intensive" course limited to six injections, especially where smaller doses are used, may be insufficient. Further evidence of this is found in the number of cases so treated coming to hospital with clinical or serum relapse. Five such cases are included among the above series. There would appear, on the other hand, to be good reason for adopting the "ten" series, provided the beneficial effect is maintained by continued mercurial treatment, the nature of which will be described later. This belief is confirmed by the subsequent behaviour of the secondary infections. Investigation was made in fourteen cases at periods of from six to twelve months after commencement of treatment; all were negative. In twenty other secondary cases treated in a similar fashion, nineteen were negative and one suspicious after six months. Such

evidence does not prove cure, but it demonstrates that a process of curing is taking place.

TABLE V.—Cases of "Tertiary" Syphilis.

[illegible]

Before beginning a consideration of the series of tertiary cases we should explain that we employ this term—admittedly an unsatisfactory one—because it is useful as expressing a syphilitic state of some years' duration; it denotes the hypersensitive period. As in the tables of primary and secondary disease, two separate series are included. It is, however, unnecessary to consider them apart.

The characteristic feature of this series of cases is the unaltered state of the blood reaction. The initial positive or negative remains constant throughout. In every case shown in the table some active syphilitic manifestation existed. Thus, in No. 936, a man aged 34, interstitial keratitis and gummata of both legs were present; while the Wassermann reaction remained negative, the gummata healed rapidly under treatment. One other case may be noticed; in No. 801 a temporary negative phase occurred about the middle of the course of N.A.B. injections. Before coming under our care this man had received five injections, which may account for the unusual finding.

We have ascertained the later results in 10 cases. At periods of seven to nine months the Wassermann reaction was still positive despite the ten injections of N.A.B. and the further use of mercury up to the time the test was made.

The following general conclusion may be drawn in respect to old-standing disease. Although the symptoms which the patient presents may be relieved, treatment fails to influence the Wassermann reaction permanently. It is true that by prolonging the treatment over several years a negative Wassermann reaction may be sometimes brought about; but in our experience such an effect is not lasting.

GENERAL OBSERVATIONS.

Although it is not strictly within the scope of this paper, treatment is so intimately connected with diagnosis that some reference to the interpretation of the Wassermann reaction may not be untoward. It is becoming more and more common for patients to be referred by practitioners, or to come voluntarily, for a "blood test." Even the evidence of a single negative Wassermann reaction is sometimes accepted as conclusive. But the Wassermann

reaction is only one of the factors upon which diagnosis should be based. In all forms of syphilis, including the secondary, a negative Wassermann reaction may be met with. Nor is there anything in the nature of syphilis to prevent the person infected with it and having a positive Wassermann reaction from developing some other disorder—for example, psoriasis or scabies. Hence, if the syphilitic nature of any lesion of the skin or elsewhere be concluded or excluded solely on the result of a "blood test" many mistakes will be made. This consideration is not purely academic. Examples of error arising in this way have frequently come under our observation. Nor should the statement that treatment has an effect on the Wassermann reaction be allowed to pass unchallenged. Treatment has an effect upon the disease, and this is shown in the primary and secondary stages by the changing character of the reaction. In the later stages, on the other hand, treatment may alleviate or remove symptoms, but in the great majority of cases it does not cure the disease, and therefore fails to influence the reaction. These statements are borne out by the findings in the foregoing tables.

What is the meaning of such persistent positive Wassermann reactions? Are they merely the result of some habit of the tissues acquired as the result of previous infection? We believe this is not the case, but that they indicate the presence of spirochaetes. The best evidence for this belief is obtained from consideration of gummatous conditions of the skin. We know that treatment causes gummata to disappear, but we also know that the chance of subsequent relapse is considerable. But gummata are the consequence of local spirochaetosis. Here, then, the persistent Wassermann reaction is clearly associated with the continued presence of spirochaetes. In the case of disease of the skin the evidence is more obvious, because we can actually observe what happens, but consideration of facts goes to show that the above statement is equally applicable to old-standing disease of other parts of the body. The spirochaetes have acquired some property enabling them to withstand remedies capable of destroying them at an earlier period of infection. This indifference of chronic infection to remedy is common to infective processes in general, and in this syphilis only obeys a recognized pathological law.

Syphilis is but one process, whether it involve skin, mucous membrane, nerve, or other tissue, and the phenomena which go to make different diseases are largely the result of mechanical interference with function. The principles upon which treatment is based vary in accordance with the duration of infection. When infection is recent—that is, in primary and secondary syphilis—two objects are in view: cure of disease and prevention of communication to others, for at this period the disease is contagious. Therefore a severe and lengthy course of treatment should be undertaken. On the other hand, in old-standing disease only symptoms are treated, because the disease is now very difficult to cure and is no longer communicable. Therefore the form of treatment may be shorter, and repeated from time to time as circumstances demand.

In forming a comparative estimate of the value of salvarsan and mercury certain considerations should be borne in mind. In the early stages salvarsan should be used to bring the disease within the scope of mercury, which finishes the cure. Salvarsan rapidly brings about the negative phase, which is maintained by mercury. This may be interpreted as follows: Salvarsan destroys the majority of, sometimes all, the spirochaetes, and mercury kills any which may have chanced to escape. But the amount of salvarsan must be adequate. As is shown in Table III, six injections are often insufficient. Nor are small doses satisfactory; not only is the favourable effect on the Wassermann reaction often wanting under their use, but when they are employed the clinical manifestations after a period of improvement may become active again, even under treatment. The "ten" series seems largely free from these objections, and although lesser amounts have succeeded in many cases, the standard of treatment should depend upon what the average, not the favourable exception, requires.

In primary and secondary stages, then, treatment should commence with the series of ten intravenous injections of N.A.B. already outlined. There appears to be an advantage in giving mercury at the same time, but the evidence in favour of this is not conclusive (see Table IV). On the

other hand, if mercury be withheld during the period of arsenical medication ded for improving the condition of the thereby diminishing the chance of subsequent mercurial gingivitis, a point of practical importance, since such an occurrence may seriously interfere with subsequent treatment.

When the salvarsan course is concluded mercury is administered by the intramuscular route for three months. The condition of the Wassermann reaction is then determined. If positive, the course is repeated from the beginning. If negative, mercury, either in the form of injections or pills, is continued until two years have been completed from the commencement of treatment with suitable rests, the Wassermann reaction being investigated every three months.

Such a course is doubtless severe and prolonged. But with ordinary care and modification, if any condition demanding this arise, it can be carried out without harming or even inconveniencing the patient. When the serious results of failure are put in the balance against it, it would appear to be entirely justified. Nor should the consequence of delaying cure be forgotten. As time passes the disease becomes more fixed; therefore, if failure result from any form of treatment, the time that has passed in carrying this out may have allowed the disease to merge into an incurable state.

In the late stages in our series ten intravenous injections of N.A.B. and then three months' intramuscular mercury were given. What may subsequently be done depends upon the clinical progress of the case. In this connexion it should be remembered that in disease of the nervous system there is often a considerable latent period, up to three or four months, before improvement becomes evident. Repetition of this course is generally necessary, and this would be expected from what has already been said in reference to the Wassermann reaction.

Finally it may be added, that even in late stages of the disease active forms of medication, such as salvarsan or mercury by inunction or injection, are preferable to other methods.

SUPRAPUBIC DRAINAGE OF THE BLADDER: THE DE PEZZER TUBE.

BY

G. S. MOTHERSILL, AND CLIFFORD MORSON,
M.D., C.M. MCGILL, O.B.E., F.R.C.S.,
ST. PETER'S HOSPITAL FOR URINARY DISEASES.

For a considerable period acute retention of urine has been relieved by puncturing the bladder with trocar and cannula. More recently a number of operations have been devised to facilitate suprapubic drainage and prevent any leakage into the pre-vesical space or upon the external abdominal wall. In certain suitable cases the insertion of the self-retaining tube invented by M. De Pezzar fulfils its purpose of draining the bladder from above the pubes without leakage or discomfort.

The bladder should be distended with at least 16 oz. of boric lotion at body temperature. An incision of about three-quarters of an inch is made just above the pubes. The sheath of the rectus is then cut; with the tip of the finger the fibres are separated and the bladder wall felt beneath. A trocar and cannula, the latter fitting a No. 28 De Pezzar tube, are then plunged through the bladder wall. The trocar is removed; the tube, guided by a stilette, is passed through the cannula into the bladder. The cannula is withdrawn and then the stilette, leaving the tube in the bladder. The end of the tube is mushroom-shaped and plugs the orifice securely, automatically flattening out with the rise of urine; moreover, the hole in the bladder is exactly equal to the size of tube, so that leakage is impossible.

After the wound has healed, usually about forty eight hours later, a wooden stopper is inserted into the distal end of the tube and the patient is able to walk about in comfort without fear of wetting his clothes. A rubber garter round the thigh holds the tube in position. So simple and practical is this device that when the patient desires to micturate he can slip the tube from under the garter and remove the wooden stopper, thus relieving nature by the artificial means as easily as by the natural.

In order to keep the urine sweet and the tube free from mucus and phosphates, the patient should be provided with a glass syringe and instructed to wash out the bladder morning and evening with pot. permang. 1 in 8,000. Acid sodium phosphate gr. xv-xxx four times daily should be given to keep the urine acid.

The tube should be removed about once a month and replaced by a new one. This is easily done with a stilette, which straightens out the proximal end, so that it can be inserted into the bladder.

This method of drainage can only be adopted when a good distension is to be obtained and no previous operation has been performed on the bladder; under such conditions there is no danger of wounding the peritoneum when handling the trocar and cannula. Haemorrhage from the bladder wall need not be feared owing to the pressure of the tube.

When haematuria is present the operation is contra-indicated because the De Pezzer tube is readily blocked by clots.

The operation is most successfully used for cases requiring suprapubic drainage of the bladder owing to deficient excretion of urea, prior to prostatectomy. As local anaesthesia is usually sufficient, the patient undergoes a minimum of shock. Well does the urologist know that the shock of a preliminary cystotomy in cases of threatened renal failure in consequence of an enlargement of the prostate will often cause death. So simple a procedure as the insertion of the De Pezzer tube reduces the shock, and, should the kidneys recover their full function, it permits the removal of the prostate without the difficulty caused by the scarring of the abdominal wall.

In cases of carcinoma of the prostate patients find the utmost relief from this method of bladder drainage; they carry on their work and experience no discomfort apart from washing out their bladders.

ANTIMONY IN LEPROSY.

BY

F. G. CAWSTON, M.D. CANTAB.,

TRIPURAN, NATAL.

THE beneficial effects of various preparations of antimony in the treatment of lepers show that they are not confined to the colloidal preparations of the drug. I have recently had the opportunity of seeing a number of leper patients who have been treated with intravenous injections of a 2 per cent. solution of tartar emetic, whilst others have received the antimony in the form of antimonial wine in a cough mixture. One patient who suffered from muscular contraction associated with anaesthetic leprosy experienced such relief from one intravenous injection of tartar emetic that he asked for more injections to be given him. A similar request was made by some female lepers whose legs were covered with extensive ulcers requiring constant dressings. Not only did the ulcers appear to be cleaning up as a result of the intravenous injection, but the patients had experienced relief. The cost of dressings at this leper institution, which contains about 750 lepers, is about £3,000 a year.

An even more striking effect of the drug was seen in a large number of leper patients requiring cough mixture. To the usual expectorant mixture containing squills was added *vin. antimonialis mxxv* to *mxx*, i.d.s. This was used as the stock mixture for leper patients, and was rather pleasant to take. Several of the patients found such relief that they continued to take the mixture containing *vin. antimonialis mxx* for some time after the cough had disappeared. From what has been observed at this asylum it would appear that the use of antimony is particularly indicated in "chest" cases.

The sodium preparation of antimony would appear to give equally promising results. At the Campbell Medical School in Calcutta Dr. Upendra Nath Brahmachari reports that some cases of leprosy seem to have much benefited under treatment with antimony given in the form of tartar emetic in 2 to 5 c.cm. doses of a 2 per cent. solution twice a week. In one case the patient had ankle-drop with marked patches of anaesthesia and leprotic nodules.

Spontaneous disappearance of the active signs of leprosy occasionally occurs in leper patients. I have recently seen such an arrest in a patient who was a partial cripple; but as a rule these spontaneous improvements are gradual, the improvement taking several weeks before all signs of active disease disappear. In the case of Sital, reported in the BRITISH MEDICAL JOURNAL for December 4th, 1920, p. 855, all the ulcers dried up in nine days or after five intra-

muscular injections of Oppenheimer's colloidal preparation of antimony, and, although the patient has been kept under careful observation by his district surgeon since his discharge from hospital, there has been no recurrence of the active signs of leprosy for five months. One must bear in mind, however, that, in view of the possible infectivity of insects with *Bacillus leprae*, exposure to fresh infection is not unlikely when leper patients are allowed to return to their homes. In their *Manual of Tropical Medicine*, 1919, p. 1650, Castellani and Chalmers state: "The difficulty of cultivating the germ on ordinary media is very suggestive of its being accustomed to live solely in animal tissues; while the abundance of the bacilli in the skin is also suggestive of that being the natural method of leaving the body."

It is to be regretted that a pathological laboratory is not attached to each leper asylum. Without such facilities at the institution itself, the means of ascertaining the cause of the spread of the infection and of determining the effect of treatment are very limited.

The healing of the ulcers under treatment with preparations of antimony is probably due to the bactericidal action of the drug; I have noticed a similar improvement in treating by intravenous injections of antimony patients who were suffering from a cloudy condition of the urine due to the presence of *B. coli* or the gonococcus. The immediate improvement that occurs after only one or more intravenous injections in such patients indicates a further way in which antimony may prove of value in the treatment of leper patients, many of whom develop a chronic cystitis, probably associated with paralysis of the bladder and *B. coli* infection. In such cases intramuscular injections of a colloidal preparation of manganous might well be combined with the antimony treatment, as I have sometimes recommended in the treatment of bilharzia cases.¹

In view of the gradual breaking down of the shells of the bilharzia ova during a course of treatment with antimony, the rapid improvement of leper patients may also be due to the action of the drug on the capsule of the bacillus. In the *Medical Journal of South Africa* for July, 1917, Drs. A. J. Orenstein and Watkins-Pitchford confirm the observations of Sir Leonard Rogers as to the value of intravenous injections of tartar emetic in the destruction of crescents in subtertian malaria. In their series of cases the danger of unskilled administration of tartar emetic injections is well emphasized.

Though several other preparations of antimony are much less toxic than tartar emetic and less liable to give rise to local reaction, oscol stibium, which is now being used in at least four different leper asylums in South Africa alone, must be used with as great caution as any other preparation of antimony. Injected into the muscle, this preparation gives rise to practically no local reaction or discomfort, unlike colloidal antimonial (Crookes), which often causes pyrexia and local swelling. Intravenously oscol stibium can be injected up to 12 c.cm. at least without toxic symptoms, provided the dose is gradually increased from an initial intravenous injection of 1 c.cm. In cases of leprosy oral administration of the drug may be combined with intramuscular injections, if so desired. Although I have not seen any very great advantage from intravenous injections of oscol stibium over the intramuscular injections, the best results would appear to have been obtained where the drug has been pushed until toxic symptoms, such as diarrhoea, have shown themselves. This is likely to occur after a total of 20 c.cm. has been given intramuscularly over a period of ten days.

If, however, the drug is injected outside the lumen of the vein selected for an intravenous injection or if it is injected into the deep tissues outside the muscle chosen for an intramuscular injection, a painful swelling gradually forms and a large abscess supervenes. Though one does not see the same painful swelling that occurs when a solution of tartar emetic is unskillfully injected, the abscess will have to be opened, and such mistakes should be most carefully avoided, especially in emaciated leper patients.

DR. E. STEINACH, professor of physiology in the University of Vienna, has been invited to the University of Stockholm, where he will continue his researches on the interstitial glands.

ACUTE RETENTION OF URINE COMPLICATED BY PERFORATION OF A DUODENAL ULCER.

By G. A. EWART, F.R.C.S.,

ASSISTANT SURGEON, ST. GEORGE'S HOSPITAL.

THE case described below presents several interesting points. It seems especially worthy of record because it affords an example of strain being the actual cause of rupture of a duodenal ulcer. An interesting question arises as to what is the best line of treatment of retention of urine under such circumstances. If I had again to deal with such complications, I would empty the bladder prior to opening the abdomen. This done, I would again do a suprapubic cystostomy on account of the general gravity of the condition and the marked urinary infection—providing ample prevesical drainage—rather than attempt any form of external urethrotomy.

Clinical History of the Case.

The patient was a man, 34 years of age, who for the past few years had had increasing difficulty in micturition, and for the past two months had noticed that his urine was very thick and offensive. There was also a history of somewhat indefinite indigestion, without, however, any vomiting, hæmatemesis, or melæna.

On March 25th, 1920, the patient, being unable to pass water, consulted a doctor. An attempt at catheterization proved unsuccessful, and, as it led to considerable hæmorrhage from the urethra, was abandoned. The patient was sent home and advised to take a hot bath, which failed to afford any relief.

At 12.30 a.m. on the morning of March 26th, when violently straining to pass water, the patient was seized with an agonizing pain in the upper abdomen which felt as if "something had given way." When eventually the patient was able to attract attention, and medical aid was summoned, the practitioner called in discovered the patient in a collapsed condition, and almost unable to give any account of himself. The abdomen was found to be rigid and tender all over. A hypodermic injection of morphine gr. 1.5 was given, which afforded some relief. On being called to see the patient I found him in great pain, but obviously somewhat recovered from his shock.

On examination it was found that the abdomen was distended, universally rigid, and tender, the liver dullness being absent. Palpation of the bladder was impossible owing to the rigidity of the overlying muscles, but on percussion it was estimated that it reached fully an inch above the umbilicus. On consideration I came to the conclusion that in addition to retention of urine the patient was suffering from the perforation of a gastric or duodenal ulcer. He was accordingly moved at once to a nursing home. On trying to pass a catheter an impermeable stricture was found lying immediately in front of the triangular ligament. Under these circumstances it was decided to open the abdomen at once, and to deal with the bladder condition at the end of the operation.

First Operation.

A general anaesthetic was given, and a small incision was made through the lower right rectus segment, with the idea of confirming the diagnosis, and for future drainage. On opening the abdomen, free gas and a fair amount of turbid fluid was discovered, the intestines were injected, and the bladder was seen to reach above the umbilicus. No attempt was made to reach above the umbilicus. The abdomen was next opened by a second fluid and the appendix. The abdomen was next opened by a second incision over the right upper rectus segment. The stomach and intestines generally were found greatly distended and the latter loaded with faecal matter. On further investigation, gas and fluid were found welling up from the region of the second part of the duodenum, where an indurated perforated ulcer could be felt. At this juncture the condition of the patient was so bad, and the difficulties of manipulation caused by the distension of the intestines and bladder so great, that it was deemed inadvisable to make any prolonged attempt at closing the perforation—under the most favourable conditions. A large drainage tube was therefore passed into Douglas's pouch, and another through the lower incision into the peritoneum, the abdominal cavity was closed. A suprapubic incision was next made and the bladder opened. A drainage tube was introduced and fixed in the bladder by means of a soft catgut stitch, and the suprapubic wound was partially closed. The urine was found to be phosphatic and very foul-smelling.

The patient, whose condition improved slightly when the abdomen was closed, was put back to bed in the Fowler position. Rectal salines and eserine sulphate gr. 1/50 were given every four hours. The morning after the operation the patient's condition was fair, considering the gravity of the case; but towards evening vomiting started, and for the next three days there was hiccough, absolute constipation, and gradually increasing distension.

On the fourth day the bowels were eventually opened after the administration of eserine sulphate, calomel, pituitrin, and various enemata, and the condition of the patient greatly improved. All drainage tubes discharged freely, the urine being

collected from the suprapubic wound in a Hamilton-Irving apparatus. From this point onwards the abdominal condition progressed favourably, and the upper incision healed without the formation of a duodenal fistula. On the eleventh day after the operation the stitches were removed. This was at once followed by the opening up of the suprapubic wound, which discharged a large quantity of pus, the drainage of the pre-vesical space having evidently proved unsatisfactory. On account of the discomfort caused by the escape of urine over the excoriated skin it was decided to deal with the urethral stricture at once.

Second Operation.

Accordingly on the twelfth day after the first operation a general anaesthetic was again given. At this second operation a No. 2 (French size) bougie after considerable difficulty was passed into the bladder. This bougie was withdrawn, and an attempt made to pass the guide of Thomson Walker's urethrotome. This was, however, found impossible owing to the tip of the instrument always catching in a small crypt, or false passage. The bougie was again passed, and the guide of the urethrotome tied to it with a short length of silk. The distal end of the bougie was then caught with forceps in the bladder, through the suprapubic wound, and the guide pulled through into position. The urethrotome was attached, passed into the bladder, and the stricture divided. A No. 14 (English) metal sound was then passed, following this a No. 12 (English) gum-elastic catheter was tied into the urethra, and finally a large drainage tube was placed in the pre-vesical space.

The vesical condition gradually improved under treatment. Three weeks after the second operation, the suprapubic wound being dry and the urine free from gross infection, the patient was allowed to get up. Subsequently a No. 12 (English) sound was passed at intervals. It is gratifying to be able to add that the patient has had an uninterrupted convalescence.

Notes by E. B. TURNER, F.R.C.S.

On being called to this case, which I then saw for the first time, at 1.30 a.m., I found the patient exceedingly collapsed and suffering intense pain. The only history I could obtain at that time was one of retention of urine, becoming acute in the afternoon, and an attempt at catheterism, which failed. After this failure the patient was advised to return home and sit in a hot bath. This was done, without relief. Soon after, when straining hard, on attempting to pass water, he felt "something give way" in the abdomen, and was at once in acute agony. I found the bladder tense and distended, the abdominal walls retracted, tenderness in the epigastric region, a small weak and flickering pulse. The patient was sweating profusely, and his expression was "pinched" and anxious. I came to the conclusion that probably a duodenal ulcer had given way, and that operation as soon as possible was necessary. The bachelor flat in which the patient was living was quite unfitted for a laparotomy, and his collapsed condition precluded immediate removal. Under these circumstances I decided to break the rule which I have always observed, not to give morphine in early abdominal cases lest the symptoms be masked, and I injected that drug for two reasons: first, that by relieving the pain he might become less collapsed, and second, that if there were a perforation the paralysis of the intestinal muscles and consequent distension of the bowel might to some extent plug the perforation and hinder further leakage. At 7.30 a.m. I found him better and much less collapsed. No other change. I got Mr. Ewart to see the case, and the subsequent developments are recorded above.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CALCIUM IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

For the last two years I have been giving calcium lactate to a majority of the 94 patients in the Ayrshire Sanatorium, and I am convinced of the benefit accruing. After considering certain facts as to calcium metabolism, and bearing in mind certain clinical manifestations of tuberculosis, I came to the conclusion that if calcium could be absorbed it might prove of great value in the treatment of tuberculosis.

The female loses a great deal of calcium with the menstrual blood; hence in cases of excessive ovarian activity calcium may become deficient. In many girls and young women, and in some women at the menopause

who are found to be also suffering from pulmonary tuberculosis, one of the distressing symptoms is menorrhagia; this condition can almost invariably be benefited by the retention of calcium. Calcium largely ceases to be retained, the retained calcium being used during lactation calcium is largely secreted in the milk, and this is probably the chief reason why lactation has such a prejudicial effect on tuberculous women. The high content of calcium in milk may be one of the reasons for milk holding such an important position in the dietary of the tuberculous; and therefore when milk is difficult to obtain it might be well to give children calcium. The reproductive organs seem largely responsible for calcium waste, and even in males sexual excesses are accompanied with calcium loss. I have found calcium useful in treating young adult males, and it would probably be useful in the treatment of neurasthenia.

The effects observed during the administration are as follows: Fall in temperature, cessation of night sweats (rare in a sanatorium), increase of energy, cessation of menorrhagia, retrogressive changes in the lesion, and benefit to anaemic conditions.

The drug has for the most part been given as a powder of 15 grains of the lactate every night during alternate weeks; it is quite easily taken in this way, though in a few cases it has been given in solution.

I should like to acknowledge the assistance I have received in this investigation from the works of Dr. W. Blair Bell of Liverpool.

EDWARD E. PREST, M.A., M.D.,
Medical Superintendent of the Ayrshire Sanatorium.

THE CEREBRO-SPINAL FLUID IN ENCEPHALITIS LETHARGICA.

DRS. DEXTER and MORLEY (BRITISH MEDICAL JOURNAL, February 5th, 1921, p. 191) relate an interesting case of this disease, in which 10 grains of hexamine was administered intravenously. They remark: "The indications seem to point to hexamine being of value." The patient, however, died. The following case is almost identical with that related—with the exception of laryngeal spasm—and this case seemed to be so hopeless that no treatment whatever was adopted beyond cleansing the mouth and general attention. The patient, however, recovered.

C. M., aged 25 years, after a mild febrile malaise lasting five days, became drowsy and complained of headache. He was restless, refused food, and was somnolent. The following morning and throughout that day the condition remained the same, but the following night he became wildly delirious, and had to be forcibly restrained on several occasions. On the third morning he was completely unconscious; there was

squint or ocular paralysis was present, no rash, cyanosis, or sweating. There was incontinence of urine and of faeces but no distension of the bladder. The urine was normal. Kneckerks were markedly increased; Kernig's sign was slightly positive, Babinski's absent, and there was no ankle-clonus; *tache cérébrale* and abdominal reflexes were present. The spinal fluid was reported on examination by a pathologist, to be in all respects normal (after thirty-six hours' unconsciousness).

For the three following days the patient remained completely unconscious. There was mild irregular fever, and on the sixth morning consciousness gradually returned and the patient regained all his normal functions. Recovery, which took place within the next few days, was uneventful.

The fact that the cerebro-spinal fluid was normal in the early stage seems to be in accordance with the explanation offered (JOURNAL, February 19th, 1921, p. 277) in the case of four fatal cases where the *post-mortem* examination showed no histological signs characteristic of encephalitis lethargica: "The probable explanation of the negative results of examination of the brains of the fatal cases is that the course of the disease was so rapid that there was not time for the characteristic changes to appear in the central nervous system." It is, however, a matter of surprise that not only were microscopic changes absent from the brain, but that the cerebro-spinal count should remain normal for at least thirty-six hours after the supervention of complete unconsciousness, and would suggest the correctness of the clinical diagnosis to be

doubtful. Since Professor MacIntosh produced a fatal lethargic illness in a monkey by means of intracerebral and intraperitoneal injection of a filtered emulsion of cerebral tissue, which did not show any histological changes but nevertheless came from a fatal case of encephalitis lethargica, the examination of the cerebro-spinal fluid in the early stages of the disease appears likely to be without any diagnostic utility.

Southsea.

R. HAMER HODGES, M.B. Lond.

TRANSVERSE CERVICAL LACERATION.

A CASE very similar to those recorded by V. Heiss, and reported in the BRITISH MEDICAL JOURNAL of February 19th, 1921, in the Obstetrics and Gynaecology section of the *Epitome of Current Medical Literature*, occurred in my own practice.

On June 11th, 1918, I was sent for by a midwife to render assistance owing to "delayed labour." On examination of the patient, who was a multipara, I found that there was an obstruction to the passage of the head along the vaginal canal, caused by the protrusion through a transverse laceration of the cervix of an elongated bag of waters. The os externum was fully dilated, and the bag of waters normally presenting there had already ruptured, but the secondary bag almost completely filled the vaginal canal, thus preventing the passage of the head. On puncturing this the head rapidly came down, and the child was born within a few minutes. The cord was divided, but when the placenta was expelled it came through the tear, so that the cord had to be returned to the cervical canal before it could be delivered. The tear was stitched up and healed completely.

Reports of Societies.

ERADICATION OF TUBERCULOSIS IN MAN AND ANIMALS.

A COMBINED meeting of the Royal Society of Medicine and the Central Branch of the National Veterinary Medical Association was held, under the chairmanship of Sir JOHN BRAND-STON, on March 14th, to discuss "The eradication of tuberculosis in man and animals." The meeting was consequent upon a previous one held on February 3rd, when the more general subject of "Diseases of animals communicable to man" was the subject of an address by Professor Hobday (BRITISH MEDICAL JOURNAL, March 5th, 1921, page 351).

Bovine Tuberculosis.

Sir JOHN McFADYEAN, in opening, said that no one could accuse veterinary surgeons of neglecting the subject of communicable diseases. To a certain extent it had become almost threadbare, and some aspects were not always presented in quite the right perspective. It was true that the diseases of animals which were transmissible to man formed a considerable list, but, apart from tuberculosis, the cases of actual transmission of these diseases in this country were about as frequent as the occurrence of deaths from lightning in summer. If all the cases occurring in this country of transmitted disease were divided equally among all the veterinary surgeons, each surgeon would only have to do with one case in three years, or, in certain of the diseases, one in ten years. Where, then, was the proposed specialist in transmissible diseases to find his material? Tuberculosis, however, was in a different category altogether. It was a disease met with in all the domesticated species, mammalian and avian, though it was now generally agreed that the avian was a distinct disease, and was transmitted rarely, if ever, to human beings. For veterinary surgeons the question almost entirely was that of bovine tuberculosis; only a very small proportion of cases of tuberculosis met with in veterinary practice were distributed among other species. Bovine tuberculosis was an independent disease. The eradication of tuberculosis from the human race, and from all species of domesticated animals other than bovine, would, as far as one could see, still leave the incidence of bovine tuberculosis absolutely unaffected. On the other hand, the eradication of tuberculosis from cattle would

reduce almost to vanishing point the cases of tuberculosis met with in other domesticated species, and would appreciably reduce the incidence of tuberculosis in man. It was impossible to say what was the percentage of tuberculosis among young bovine animals up to the age of 2 years; slaughterhouse statistics and records of tuberculin testing on a sufficient scale were lacking. But there was evidence to show that the incidence was not high in young animals. It rose with age, and became serious only in animals over 2 years old. Among adult cattle the proportion affected was not less than 30 per cent.; he believed it to be higher. The eradication of tuberculosis from the cattle of this country was only possible if it could be carried out regardless of cost. It would involve the compulsory tuberculin testing of all cattle and the slaughter of the animals which reacted. That would mean the slaughter of from 750,000 to a million cows or heifers. No Government would find the money to compensate for such a slaughter, and even if it did take place the result would be so to reduce the milk supply as to drive up the price to an impossible figure. If instead of slaughtering all the affected animals they were placed in isolation such isolation would have to be permanent, otherwise the disease would not be eradicated, and it would extend from animals known to be affected to animals which had been put aside provisionally. But the owners of valuable pedigree herds might do a great deal towards the eradication of tuberculosis from the herd. Most of them were wealthy men, and had facilities which made eradication a possible policy. The Research Institute in Animal Pathology at the Royal Veterinary College had recently made an offer to the owners of any pedigree herds in this country to lend free assistance, including the supply of tuberculin, and some few very valuable herds had already been placed in the hands of the Institute. If wholesale measures of eradication were impossible, a more moderate measure to prevent the infection of human beings might be taken by reviving the Tuberculosis Order, which was introduced in 1913 and suspended on the outbreak of the war, to cut off the supply of milk from cows with tuberculosis of the udder and from other cows that presumably were passing tubercle bacilli. The infection through meat had no doubt been immensely exaggerated in the past; milk was the chief avenue of infection, and accordingly he proposed:

That the Fellows of the Royal Society of Medicine and the Central Branch of the National Veterinary Medical Association, assembled in joint meeting, are of opinion that the prevalence of tuberculosis among cattle in this country continues to be a serious menace to the health of human beings, and that to counteract this danger the reintroduction of the Tuberculosis Order, which was suspended in 1914, is urgently required.

The Milk Problem.

Professor LYLE CUMMINS (Cardiff), who seconded the motion, referred to the great amount of patient research being carried on by Dr. Stanley Griffiths and other workers, and he had no doubt that in the course of time much more would be known about the actual importance of bovine infection to man. It could be said for certain that bovine infection gave rise frequently, in children at any rate, to meningitis. A large amount of abdominal tuberculosis was due to the same cause. But, taking the whole pool of human tuberculosis in England, what really counted was phthisis, and in this connexion he recalled the interesting light thrown on phthisis by Dr. Brownlee in his recent statistical investigation, which showed that throughout Great Britain there were two types of mortality—a young adult type and a middle-aged type; and that while the young adult type led to a preponderance of deaths in certain areas, chiefly great scattered areas, it was the middle aged type of death chiefly which obtained in London and other great aggregations of population. The young adult type appeared not to be correlated in any way with milk, whereas the distribution of infected milk appeared to be definitely linked up with the middle-aged type of death. This circumstance did suggest that, although death eventually occurred, the total period of the disease was prolonged in the class of cases in which milk infection might be concerned, so that there must be some influence as a whole favourable to the people where the tuberculosis terminated in the middle-aged type of mortality as compared with the people who died rapidly

of the young-adult type. Some of that prolongation of the effects of tuberculous infection might possibly be due to a partial vaccination by a bovine strain. He knew that this was dangerous ground, but such a vaccination was very plausible and seemed to cover a great many of the facts. On the other hand, he would regard the advocacy of such vaccination as entirely unjustifiable, because this vaccination, even if it existed, could not be controlled. He could not free his mind from feeling that it did exist, and played a very important part in the great diminution of fatal phthisis which had taken place in recent years; but to advocate it was a different thing, for the knowledge of it was not yet established, and, even if it were, it would have to be admitted that milk as a vaccine could not be controlled as regards dose. The only policy, therefore, was to better the milk supply and diminish infection. The means of transportation and distribution of milk were extremely uneconomic. This essential nutrient was sent over the country in very dilute form. The volume of milk in proportion to its nourishing qualities was large. It was a matter for the physiologist to tell them whether, without depriving children of necessary vitamins, the bulk of milk might be diminished by drying processes, and yet the risk of producing deficiency disease be negligible. This voluminous and difficult material was liable always to contamination by other germs in transit, and if it could be diminished in volume, without losing any physiological essential, a purer milk supply would be assured. Here again, however, our knowledge was not yet complete.

A Plea for Comparative Pathology.

Sir CLIFFORD ALLBUTT said that he would be only wasting the time of the meeting if he were to enter upon the large field of tuberculosis in the endeavour to illustrate or enlarge that subject. Moreover, those present had heard technical addresses, and would hear yet others, dealing with these matters in an intimate way which he, on this occasion, did not propose to follow. He would take another line—a paradoxical line—by asking: What was the good which tuberculosis had done for the human race? Had not tuberculosis brought certain benefits to mankind? He remembered in his early days, when he began practice in Yorkshire, that the Yorkshire dales—those long valleys of the Wharfe and the Swale and the Don—were full of enteric fever, which was endemic in those places. It was looked upon either as a kind of visitation from God or as something in the atmosphere, in any case wholly outside human interference. So things went on until the appearance of the excellent work which was done upon the enteric bacillus, and thereby some notion of the way in which disease arrived and might be met got driven into the minds of the people. Before that time—and often, he regretted to say, since that time—the farmsteads in those valleys were centres of stench, and vermin, and disease, and one might as well have talked to one of his own bullocks as to the farmer on the way in which disease arose in those places and how it might be counteracted. The same was true of the squire; he was just as stubborn as the rest. And in that respect the enteric fever brought with it this benefit, that it did have the effect of informing the people as to the causation of disease. It was useful to consider in what respect tuberculosis had done something of the same kind. Koch's discovery of the tubercle bacillus in 1882 was like a stone cast into a stagnant pool. People began to realize in what way disease was bred amongst them—that it was due to a living virus which it was for them to discover and counteract. In that way a great piece of education was carried right among the people by tuberculosis. The thing was taught even to the babes and sucklings—to such innocents, for example, as the butcher and the milkman. Even these people were obliged to become, in a sense, scientific. Only recently, to take another example, the world had been made aware of the wonderful results obtained in the case of glanders by the veterinary schools in the war. Glanders was diminished—he might almost say obliterated—and the work with mallein was seen by every stable boy. That was the first lesson. These schoolmasters chastized us with scorpions, but they also instructed us. The second lesson was that if a successful campaign against these diseases was to be undertaken it must be a long and slow and laborious business. That was what the public soon

now would not see. The public would bestow a relatively small sum for investigation and ask for results in three months. Tuberculosis was teaching the public, however, that the investigation of any one of these diseases, or even parts of any one of them, must be long, slow, and extremely expensive. In the growing of crops it was necessary first to clear the ground, and then to plough and harrow, which took a long time; and even after the seed had been cast it lay apparently dead for months before the blade appeared. Not less patient must be the investigation of disease. It was a long and costly process, and the public must learn that means had to be provided for its continuance, while the men who were engaged upon this enormously difficult question must also recognize that it would take a long time, and they must work with faith and hope, sure that the results would come some day, though they could not say when. The third lesson was this: that if these great questions were to be understood—and they were confining themselves to the question of immediate pathology, of tuberculosis among other diseases—there must be a combination of forces. The large principles of disease would never be determined until there was a system of comparative pathology, with establishments of various kinds for its study on a large and sufficient scale. At present the work was being done, though with very great success, in departments which were almost isolated. Good work had been done alike by the entomologists, and in the veterinary schools and in human medicine, but all were working in their independent ways. So far as he knew, pathology was the only subject which had hitherto declined to call—or at any rate had been supine in calling—the comparative method to its aid. Anatomy could not live without comparative anatomy. Law made use largely of comparative history; the study of religion, of philology—wherever one looked, the same comparative method was followed. None of these subjects could have attained its present position without comparative study. The establishment of the study of comparative pathology, and the linking together of the several departments, would greatly aid and encourage investigation, and would counteract the tendency to extreme specialism; there must be specialism, of course, but it need not involve isolation.

Sir Clifford Allbutt went on to say that he was sanguine enough to believe that, with the presence of distinguished veterinarians at the Royal Society of Medicine that evening, they had the beginning of a comparative pathology. They had heard what Sir John McFadyen had said; they had recently had placed in their hands a new edition of the work on pathology by Major-General Smith, and they knew the admirable work done by Professor Hobday and others, as exemplified in the *Journal of Comparative Pathology* and elsewhere. Mr. Scott of Bridgewater and others were working hard at the establishment of a systematic study of pathology, embracing more than their own subjects. On his (the medical) side he was afraid the links were few; one of the strongest was the chairman of the evening (Sir John Bland-Sutton). As Professor Stanley Gardiner had remarked the other day, millions of the best of our race owed their lives to the labours of forgotten men of science who laid the foundations of our knowledge of the generations of insects and flat worms, the modes of life of lice and ticks, and the physiology of such lowly creatures as the amoeba, leading up to the parasites of malaria, typhus, dysentery, and so on. All that knowledge thus acquired would bear its best fruit in the field of comparative pathology. Who was not astonished to read in the newspapers recently that even herrings depended on sun spots? The whole doctrine of evolution was comparatively recent and had not yet come into pathology as it ought to have done. He was thankful that the veterinary profession had come to their support that evening. While there could, of course, be no fusion, co-operation in common work was feasible, and this should obtain, not merely between human and veterinary medicine, but between entomologists also, and workers in the whole field of animals and plants. That must be largely the work of the universities. He was not entitled to speak for any other university than his own, but at Cambridge they would never think of establishing a veterinary school. The practical work must be learned in special large centres. He did not know what might be the position in the northern universities, but neither

Oxford nor Cambridge was so placed as to be able to have—even if it ought to have, which he did not believe—a veterinary school. It was, however, the business of the universities to establish schools of comparative pathology on those broader and more abstract lines, while the actual work for the professions might continue to be done in the large centres. Veterinarians had their own school, and had, and always would have, their one portal. But it was the business of the universities to link up, if possible, all these various practical fields, and to teach the application of certain broad scientific principles. It was these three lessons which, he ventured to think, tuberculosis had helped to teach mankind, and to that extent it had benefited the race. He was very glad to hear the other day that a committee for comparative pathology had been started, and that Sir David Prain was to be the chairman. That showed, at any rate, a desire that it should be on the broadest lines of comparative work, which included work on plants, for they must remember that when they were speaking of the pathology of enteric fever and similar diseases they were speaking of plants and of unicellular plants, which had so vast an influence over the destinies of mankind.

Dr. A. C. ISMAN said that an immense amount of patient and careful work had been done since Koch's discovery to establish the extent to which the bovine type of bacillus infected man, and which type, human or bovine, was the more important in human disease. On taking cultures from all types of tuberculous disease in man it had been found that the bovine infections for all ages worked out at 18.7 per cent. of the total number of cases. But on analyzing these forms of tuberculous infection in man great differences were found. In phthisis, taking all ages, the percentage of bovine infection was only 1.4, while cultures made from tuberculous glands in the neck in young children during the first five years of life showed the bovine infection in 85.7 per cent., and between the ages of 5 and 10 in 65 per cent. The bovine infection, therefore, was a reality, and great precautions must be taken about the consumption of infected foodstuffs. Unhappily, in the case of tuberculous infection, there was not, as yet, any certain means of diagnosing the disease at an early stage. Some test was wanted whereby the disease could be diagnosed before bacilli appeared in the sputum.

Dr. HULLIDAY SUMNERLAND argued for agreement upon certain general principles. After Koch's discovery, right up to the present time, nine people out of ten when asked what was the cause of tuberculosis would reply, "The tubercle bacillus." Philosophically, that was wrong. Tuberculosis was the result of the bacillus on the one hand and of a lack of resistance of the body on the other. The fighting bulls of Spain were free from tuberculosis because they led a life in the open. Tuberculosis was an expression of an imperfect civilization. Apart from the discovery of a definite specific, like "60S" for syphilis, all their efforts would be only partially successful until the resistance of the race was improved and man was made to lead a healthy life. The idea that any good would be got from tuberculous milk as a means of vaccination seemed dangerous. It might be uttered in a medical meeting without doing any injury, but it would be taken up by dairy farmers and agricultural papers and used as an argument against doing anything in the matter of tuberculous milk. If there was anything in this vaccination, let all children be vaccinated with cultures of tubercle bacilli, but first let the results of protective inoculation both of cattle and guinea-pigs be called for; so far these results had failed to warrant the application of that theory to man. He thought it dangerous to rely upon laboratory diagnosis in medicine. While nothing was perfect, they had at present in clinical methods of percussio and auscultatio, verified by x-ray examination and the tuberculin test, a good working technique whereby tuberculosis might be diagnosed at least two years before the bacillus appeared in the sputum.

Professor F. HOBDAY said that workers in human and veterinary medicine covered much ground in common, and by working in unison better results would be obtained than if each side kept within a watertight compartment.

Sir JOHN MCFADYEN, in reply to the discussion, said that the incidence of tuberculosis at different ages in man could be explained without assuming that milk from tuberculous cows was an important factor at all. He denied

that Spanish bulls of the ring were free from tuberculosis, and he knew that tuberculosis might occur to a somewhat serious degree among ranch cattle which had never been under a roof.

The resolution calling for the reintroduction of the Tuberculosis Order was carried unanimously.

THE NON-OPERATIVE TREATMENT OF SURGICAL TUBERCULOSIS.

At the meeting of the Medical Society of London on March 14th, with Sir WILLIAM HALE-WHITE, the President, in the chair, a discussion took place on the non-operative treatment of surgical tuberculosis. The opening paper was read by Sir HENRY GAUVAIN, medical superintendent of the Lord Mayor Treloar Cripples' Hospital and College, Alton, Hants. He said that he would confine himself to tuberculous disease of the bones, joints, and glands, in which conditions non-operative treatment might now be usually adopted with confidence and a reasonable assurance of success. In certain other non-pulmonary tuberculous lesions—for instance of the kidney—operative interference still had an essential field, but in such situations as the meninges of the brain treatment of any sort remained almost futile. Operative treatment of an active tuberculous lesion was based on a false pathology, except when the lesion occurred in a situation where its presence was incompatible with life. Launelougue showed that the progressive extension of a tuberculous abscess towards the skin was not a mechanical phenomenon, but was the result of primary infection and subsequent excentric destruction of tissues by tuberculous elements advancing in the manner of a neoplasm. Hence was evolved a radical treatment which had arrived at the total extirpation of tuberculous tissues, but this practice, possible and efficacious with small tuberculous foci, exposed the patient to serious danger when applied to extensive bony lesions. The mortality, both immediate and indirect, after major operations was appallingly high, and in the survivors, especially growing children, the extensive mutilations gave deplorable orthopaedic results.

To the "tuberculous" theory the conservative surgeon opposed a theory based on the defensive resources of the patient. A tuberculous lesion provoked a reaction, there was the formation of a zone of resistance about the focus of the disease by the formation of fibrous tissue which encysted, limited, and tended to prevent the progress of invasion. Thus the issue was the result of two opposing forces—the disease which attacked the organism and the reaction which this attack provoked. It appeared reasonable to reinforce this natural defence and diminish the virulence of the attack of the bacillus, limiting in this way its progress. To this day there was too great a tendency to concentrate unduly on the local lesion, and to disregard the fact that the patient himself had contracted a general disease, of which any particular lesion or lesions were merely local manifestations.

The title "non-operative treatment" of surgical tuberculosis conveyed no suggestion as to what the treatment, if non-operative, might be. Treatment, where operation was avoided in these conditions, was usually termed conservative, but that term again was open to criticism. He defined conservative treatment in surgical tuberculosis as the adoption of all measures tending to improve the patient's general health, to increase his powers of resistance to tuberculous disease, and to preserve or restore the part or parts attacked, in contradistinction to radical treatment, which aimed at the cure of the disease by the removal of the local lesion. Such a definition was the very antithesis to lack of treatment; it necessitated very active, numerous, and complicated methods being employed, and implied that surgical procedures were by no means necessarily excluded. Chronic disease, which of necessity involved lengthy treatment, had for too long been regarded from the purely pathological point of view, the intellectual and industrial aspect of the problem having been ignored. This state of affairs should have been remedied long ago. All child patients should be educated, and manual instruction should play a large part in the scheme; adolescents should be trained in work suited to their limitations, and adults occupied. To assist in carrying out that part of the work, on the educational side fourteen trained teachers,

and on the technical five trained instructors, were employed at Alton. Sir Henry Gauvain advocated the establishment of properly equipped "preventoria" where such children could have preventive treatment under the best climatic, hygienic, dietetic, and educational conditions, and under skilled supervision. Such a preventorium was in contemplation at Alton.

A detailed description of conservative treatment would include consideration of general treatment, involving climatic, hygienic, dietetic, drug, educational, and other methods; and local treatment, which was concerned with the correction or prevention of deformity and was largely orthopaedic in character, but was subject to those limitations which the fact that the patient was tuberculous enjoined. Under the latter heading might also be included surgical measures, which had still a place, such as the aspiration of tuberculous abscesses of bony origin. Adjuvant methods of treatment, including heliotherapy, balneotherapy, chemotherapy, vaccine treatment, and the therapeutic employment of x rays and other electrical agents, represented perhaps the most interesting advances made in the non-operative treatment of surgical tuberculosis. Auxiliary methods were of importance for the patient's general well-being, and comprised attention to the teeth, skin, throat, nose, ears, and eyes. Included also under auxiliary methods was a branch institution where chronic cases not requiring any special treatment might be detained indefinitely, and thus give room at the hospital for more acute patients urgently needing specialized care. In regard to after-care, all patients who had suffered from surgical tuberculosis should have the continued advantage of occasional skilled supervision, and no special hospital for the treatment of these conditions could be considered complete unless it possessed an out-patient department where discharged patients might be periodically examined, advised, and assisted. Not only was medical help required, but advice in the choice of occupation and assistance in obtaining suitable employment should be forthcoming. Lastly, the speaker's own experience was that it was fallacious to suppose that adults did not respond well to conservative treatment, though operative aid might more often be called for in those cases.

Sir ANTHONY BOWLBY said that there was a period when the surgeon set out by operation to eradicate the tubercle bacillus; after a very considerable experience of surgery he thought he could say that this was a thing the surgeon was unable to do. Here and there a surgical lesion might be removed; but what was now appreciated was that whilst the surgeon could not kill the tubercle the patient could, only the patient required perseverance and encouragement. He had been convinced, as a result of post-mortem investigation, that it was of no use trying to eradicate tubercle by local operation, because, on examining patients after death, it was invariably found that they had tubercle in some other part of the body. The growth of tubercle in bone acted as a solvent on the bone salts, and as a consequence a very considerable amount of bone was gradually dissolved and the fibrous stroma of which the bone was composed was ultimately removed. The patient himself did what the surgeon had often tried to do, but whereas the patient actually did remove the tuberculous material, the surgeon by his intervention took away a good deal of bone which was quite capable of recovering. It was not sufficiently appreciated that a great amount of tuberculous bone could be got away without external operation at all. Nevertheless the living surgeon was not altogether out of court. He had to act, in to remove the dead material. In a great many cases, when the process had ceased, there was left behind a good deal of material, either caseous or purulent material, or purulent fluid. The surgeon, however, did not require to remove the former, but the latter he could remove by aspiration. Tuberculous disease of the knee was sometimes better treated by operation, whereas tuberculous disease of the hip was in no way well treated by operation, and when the two conditions were compared it was easy to realize that the surgeon might be able to remove the whole of the tuberculous tissues of a knee, whereas the so-called excision of a hip seldom removed the whole disease. At the present time it was not sufficiently appreciated how much was required for the treatment of this class of patient. People were content to say that the patient should be treated out of doors, and so on, but, as Sir Henry Gauvain had rightly

said, the question was not one of convalescence but of treatment. And it was of no use allowing a child with a tuberculous hip simply to lie outside in the sun without appliances or any other form of special treatment. A great deal of incomplete treatment was done in these cases. Sir Henry Gauvain had demonstrated at Alton how much more than merely passive treatment was necessary.

Mr. T. H. KELLOCK said that when surgeons used to operate in cases of tubercle, except in amputations possibly, all that they did was to remove the debris, the result of the disease, and they could not hope by any operation for tubercle to cure the child. Even locally the disease was too far spread for them to hope that by excising the hip-joint or the knee they were going to remove the whole of the tuberculosis. Mr. Kellock urged the value of iodine and its preparations, which killed tubercle if thoroughly brought into contact with the organism. The application might be constitutional through the agency of the blood, and local at the seat of the disease. If a patient were given sufficient potassium iodide the disease might be, if not cured, at least brought to a standstill. Given clean tubercle, without suppuration, potassium iodide should be pushed in very large doses over a long period. In local treatment the application of the iodine was even more important. In tuberculous abscess the iodine in liquid or gaseous form must be brought into close contact with the whole of the walls. An abscess should be aspirated, and the contents replaced by an equivalent, or almost equivalent, quantity of some germicide. Personally, he always used a strong solution of iodine and potassium iodide, and, by combining the local and the constitutional treatment, a very large proportion of clean tubercle could be satisfactorily dealt with.

Dr. Gordon PUGH described various methods of fixation in spinal disease of children, including a special appliance which he used at Carshalton. Mr. W. H. TRETHOWAN referred to the peculiar difficulties of the out-patient department, and the necessity for standardized treatment in hospital. He praised plaster fixation, which he thought far superior to the Thomas splint. Mr. GILFING BALL also spoke of the difficulty of out-patient treatment, and agreed with Mr. Trethowan in his criticism of the Thomas splint for spinal disease. In his experience it was very seldom that tuberculous disease of the hip-joint completely recovered. The cases were nearly always left with a certain amount of stiffness and deformity. Mr. P. B. RORN said that in closed tuberculosis treated without operation, under proper conditions, and in good surroundings, the prognosis was excellent. He quoted statistics from an institution in Switzerland indicating that 80 or 90 per cent. of cases were curable, and in an average time of fifteen months. In open tuberculosis the prognosis was very doubtful.

Sir HENRY GAUVAIN was precluded by the lateness of the hour from replying, but he commented on the fact that every speaker, without exception, now approved the non-operative treatment of tuberculosis.

EXOPHTHALMIC GOITRE.

THE discussion on exophthalmic goitre, which had occupied the Clinical Section of the Royal Society of Medicine, combined with the Sections of Medicine and Surgery, for two evenings (BRITISH MEDICAL JOURNAL, February 19th and March 5th), was brought to a close on March 11th.

Mr. C. A. JOLL, in reopening the discussion, said that in the true disease the danger of the operation and the degree of benefit likely to follow depended very largely on the length of time during which the disease had been present. He advocated the ligation of the superior thyroid vessels in very mild early cases, which he had occasionally seen cured by this procedure, and as a preliminary step in grave and advanced cases. The operation was simple and very suitable for local anaesthesia, and a striking improvement often followed. It was generally necessary to resect a part of the gland three to six months later, and this could be done at that stage with less risk than would be involved in immediate resection. Mr. Joll confessed himself unable to understand those who claimed that it was necessary in operating for exophthalmic goitre to remove every scrap of gland tissue in the neighbourhood of the recurrent nerve. If a small

portion of the gland were recurrent nerve paralysis did not occur, that the incidence of this disease was very high where this precaution was taken. He had often examined this little gland, and in no case had he seen hypertrophy. The solution to the problem of the disease seemed to him to lie in more comprehensive resection, and haemorrhage during operation.

Dr. LEONARD WILLIAMS stated his conviction that there was no more justification for operating on the gland than for operating on the kidneys in a case of diabetes. The worst symptoms of the disease—cardiac, and, following upon that, mental and nervous—were due not to the thyroid, but to the thymus, which had been too little considered. The thymus gland was enlarged in over 85 per cent. of the cases. He was not in the least anxious to take from the thyroid the part of the villain of the piece and give it to the thymus, but if a gland was to be attacked at all it should be the thymus.

Dr. C. M. WILSON said that since 1912 there had been practically no advance on the subject, and medical men were as far from agreement now as they were then; and that seemed to him a remarkable state of affairs, the more so because it had arisen, not around some difficult question of causation, but around the question of results. The terms used when speaking of the disease did not succeed in conveying to others the type of case intended or its severity, and that difficulty might be overcome by expressing in figures or curves on charts the character of any one case at any one time. One of the reasons for their backwardness in solving the problem was because they had not all got the same standard. There were too many advocates of different procedures, making too many comparative statements.

Dr. KINNIE WILSON was disappointed that so little had been heard in the discussion about the pathology of a disease treated in so many different ways. He agreed with Dr. Leonard Williams that exophthalmic goitre was not a disease of the thyroid. He would regard it as essentially a neuro-glandular disease. It was impossible to dissociate the nervous aspect of exophthalmic goitre from any of its other aspects.

Dr. MARTIN BERRY gave an account of some cases in which x-ray treatment was successfully applied. He believed that in no case of exophthalmic goitre was x-ray treatment contraindicated, except, possibly, a case in which nervous dyspnoea was present, due to actual pressure on the trachea.

Dr. HECTOR MACKENZIE, the original opener of the discussion, said that allusions had been made to his "conversion" to surgical treatment, but the fact was simply that in earlier years, although he had occasional good reports of operations, and had always been of opinion that surgical treatment in certain cases was probably the best treatment for the disease, he was disheartened by the total mortality; but since 1915, when he was first introduced to Mr. T. P. Dunhill's treatment with local anaesthesia, he had found the results of operation as good as they had formerly been had under a different procedure. Of the cases on which Mr. Dunhill had operated for him, not one had been lost, and all had benefited. The chief point which came out of the whole discussion was the surgical advance which had been made, and the fact that the operation now, by expert surgeons, was comparatively safe. He disagreed with those surgeons who had advocated strongly the ligation of the arteries. This operation might be looked upon as comparatively safe, but he had never seen any really satisfactory result from ligation of the arteries alone. If operation was going to be undertaken, it was not worth while wasting time tying arteries when far better results could be got by thyroidectomy. Dr. Mackenzie went on to analyse some of the statistics which had been presented by the x-ray advocates, and maintained that they were not as convincing as might appear at first sight; many of the cases reported to be benefited by x-rays were not marked cases of the disease. In conclusion, the outlook for patients with exophthalmic goitre was very much brighter now than at any previous time. Surgery practised on the lines of prudence would help to restore many to health, and would save an increasing number from drifting into a

Every effort should, however, be made to cure the disease by medical means, and if the undertaking medical treatment must be made but after as well as before it.

Mr. T. P. DUNHILL, who also replied, said that in cases in which ligation of the arteries could be done easily it was not necessary, and in the cases in which it might be regarded as quite necessary it was dangerous. When it was necessary for this to be done it was almost as easy and safe to remove part of the lobe. The discussion had suggested to him that there should be only one person in charge of the case, and he the physician, and that so long as the physician was piloting the patient back to health there was no need to bring in the surgeon. But when the physician found that the case was not going as it should it became a matter for the exercise of a dual intelligence, and it must be left to the surgeon, of course, to decide as to the best time to operate, the nature of the anaesthesia, and the extent of the gland to be removed.

OCULAR PALSIES.

The Sections of Neurology and Ophthalmology of the Royal Society of Medicine, Dr. JAMES TAYLOR presiding, combined in a discussion, on March 10th and 11th, on the subject of ocular palsies, accompanied by a demonstration of cases. The discussion suffered to some extent from the extreme complexity of the subject, and from the fact that most speakers went on lines of their own, each describing a different type of palsy.

The subject was introduced by Dr. GORDON HOLMES and Mr. LESLIE PATON. The former gave a careful exposition, fully illustrated, concerning mainly anatomical investigations into the nervous and muscular structure involved. Mr. Paton sketched the various categories into which oculomotor paralysis might be divided. His grouping was: (1) Paralysis of central and cerebral origin, comprising three subgroups: (a) supranuclear lesions, (b) infranuclear lesions, (c) nuclear and nerve-root lesions; (2) paralysis of extracerebral origin—that is, of nerve trunks—again comprising two groups: (a) intracranial and (b) intraorbital; (3) paralysis of muscular origin. Nuclear ophthalmoplegias or ophthalmoplegias proper could be subdivided into acute and chronic types. Good examples of the infective type of acute ophthalmoplegias were found in lethargic encephalitis, influenza, and syphilis, but in a very definite proportion of acute ophthalmoplegias no infective agent could be found. The most important form in chronic progressive ophthalmoplegia was that occurring in tabes and general paralysis of the insane. Besides these, there were certain ophthalmoplegias of congenital origin and others which were of a distinct familial type.

Mr. BISHOP HARMAN commented on the comparative rarity of these cases. In a consecutive series of 5,000 patients he found only 27 cases of ocular palsy, 17 of whom were males and 10 females. Paresis due to injury headed the list with 7 cases, syphilis came next with 5, and general vascular disease or degeneration with the same number. Two cases due to exposure were likely to be a bone of contention between the neurologist, who was not inclined to admit such a cause, and the ophthalmic surgeon, who credited it. In one of these there were undoubted manifestations of inflammation over the affected muscle, and both cases were cured with notable rapidity. He agreed that, apart from the cases of paralysis due to direct injury to the bones of the orbit and his two cases due to exposure, the occurrence of such a paralysis was a sign of serious general disease, but his cases afforded no evidence that life was thereby shortened.

Dr. KINNIER WILSON laid stress upon the difficulty of determining the exact etiological factor, but thought that unilateral cranial polyneuritis had to be regarded as a distinct clinical possibility. Mr. J. GRAY CLEGG described a case of ophthalmoplegia in Graves's disease, and Mr. FOSTER MOORE also dealt with the condition in Graves's disease, and said that it seemed probable that when deficient movement of the eyes occurred in this disease it was due to impairment of the function of the muscles, while marked exophthalmos would introduce a mechanical factor contributing to the same result. Dr. JAMES COLLIER described a case in which there was bilateral palsy of the sixth nerve following spinal anaesthesia. Mr. M. L. HINE

spoke particularly of the group of chronic nuclear palsies and reviewed the literature. Dr. WILFRED HARRIS raised the question as to whether a rheumatic neuritis of the motor branches of the third or sixth nerve in the orbit could be fairly diagnosed. The PRESIDENT expressed his scepticism about paralysis of the ocular muscles of so called rheumatic origin. He had been watching for a good many years cases of seventh-nerve paralysis and had never yet seen sixth-nerve paralysis associated with it.

Dr. GORDON HOLMES, in summing up the discussion, said that his experience of ocular palsies had been considerable, especially since he had been on the staff at Moorfields, and he was always conscious of the difficulty of deciding what any palsy might be due to. It was usually only by means of associated disease that a presumptive diagnosis could be made. In all groups of ocular palsies there was a considerable paucity of careful histological work. No doubt muscular weakness was due to muscular conditions in a certain number of cases, but his experience was that in a considerable proportion of patients with Graves's disease with ocular palsy there was relatively little proptosis.

PATHOLOGY OF INFLUENZA.

At a meeting of the Pathological Section of the Liverpool Medical Institution, held on February 10th, with the President, Dr. J. E. GEMMELL, in the chair, the adjourned discussion on Dr. ADAMI's paper on "The pathology of influenza" (BRITISH MEDICAL JOURNAL, January 8th, 1921, p. 48) was opened by Dr. R. J. M. BUCHANAN. Dr. Buchanan said that in the epidemic of 1918, from the U.S.A. troops about 450 cases of the disease were admitted to three of our auxiliary hospitals to which he was consulting physician. The outbreak was serious, and it soon became evident that the cases could be divided clinically into four groups: (1) The mild catarrhal type, (2) the pneumonic type, (3) cases with physical signs of bronchiolitis, (4) cases of profound toxæmia, with little or no respiratory phenomena, in whom coma vigil was the rule, and who, with few exceptions, died. His clinical observations led him to the conclusion that in that epidemic they had to deal with a triple or multiple infection process. He briefly described the history of the previous epidemics, and showed that the same division into groups was seen even in the 1889-92 epidemics. He thought this similarity in classification in different epidemics supported the theory of multiple infection, and in support of this he quoted Washbourne, Lister, Gocher, Gillespie, Cole, and Sutton and Sevier.

Professor ERNEST GLYNN quoted some experiences of the influenza epidemic among the American soldiers in Liverpool: direct films from the sputa of 13 cases showed pneumococci and influenza group in 5, influenza group in 2; blood cultures from 70 cases showed pneumococci in 9, pneumococci and streptococci in 2, influenza group in 2; 22 post-influenza empyemas showed pneumococci in 9, streptococci in 8, pneumococci and streptococci in 1, pneumonia and *Staphylococcus aureus* in 2, streptococci group in 1, while 1 was sterile. He quoted several cases in which the bacilli of the influenza group were numerous in the trachea and bronchi, but pneumococci scanty, whereas in the pneumonic lung alveoli the reverse obtained. A mixed influenzal pneumococcal and streptococcal vaccine which he had made was extensively used for treatment of the American troops, but he had no reliable data as to its value. As "influenzal pneumonia" was often accompanied by septicaemia, vaccines seemed inadvisable on theoretical grounds.

Dr. E. CROXIN LOWE, by means of a series of lantern slides and sections, pointed out the well recognized importance of the post-nasal space and accessory sinuses as the focus of primary infection in influenza. He showed that while in the simple pyrexial cases the intensely influenzal mucosa of those areas gave rise to frequent epistaxis, etc., and was associated with a toxæmia, in other cases which developed later the severe fulminating type of influenza, the condition was due to a generalized bacteriæmia, originating in the infection of the congested pharyngeal veins and extravasated blood in the submucosa of this region. This was carried probably often in the form of minute infective emboli, travelling by the normal anatomical route, and would be arrested in the terminal

arterioles of the pulmonary artery, which were situated around the terminal bronchioles. In this way he considered, as Dr. Herbert French had suggested elsewhere, that the rapid and earliest lung infection took place, giving rise to a peribronchiolitis of haemic origin, which would account for the pathological appearances so constantly found present in these more rapidly fatal cases. The protective functions of the ciliated lining epithelium having been thus damaged allowed of a later infection by direct extension from the upper air passages along the bronchial tract. He pointed out that from this point of view the three important factors in treatment were regular local hygiene of the post-nasal space, prophylactic vaccination against the three organisms principally concerned—namely, *B. influenzae*, streptococci, and pneumococci—while in the actual treatment of the septicaemic type of case the prompt, early, and adequate administration of curative streptococcal or pneumococcal serums should biologically be the right treatment; generally 50 to 100 c.cm. of serum, given intravenously and twice daily, would be required.

Dr. A. GORDON GILLAN said that when on service with the British Expeditionary Force in the spring of 1916 he observed an outbreak of influenza of a mild type without any respiratory complications, which was chiefly classified as P.C.O., or trench fever. Early in 1917 he noted cases of influenza complicated with pneumonia and other respiratory affections, but in 1918, when officer in charge of the Military Hospital, Gibraltar, two severe outbreaks of influenza occurred; the first, in June, was in several cases accompanied by respiratory complications, but in no instance with a fatal termination; the second, in October, was much more virulent, and showed signs of marked toxæmia. In this latter epidemic the respiratory type was much more prevalent, especially in the form of lobar pneumonia, often accompanied by general bronchitis and most severe cyanosis. In 355 cases, 77 developed pulmonary complications, and of these 18 terminated fatally. It was noticeable that no soldier affected in June contracted the disease in October. In the sputa which were examined the bacillus of influenza and the pneumococcus were found.

At a meeting of the Sheffield Medico-Chirurgical Society, held on March 8rd, with the President, Dr. F. J. SADLER, in the chair, Sir D'ARCY POWER read a paper on the palliative treatment of aneurysms by wiring. He showed Colt's apparatus for the rapid and aseptic introduction of wire into aneurysms, and pointed out various points of practical importance in its use. He then gave details of the more recent cases of thoracic and abdominal aneurysm in which he had employed this method of treatment and the subsequent history of the patients whose cases had been recorded in the *Proceedings* of the Royal Society of Medicine in 1912. One of the cases was illustrated by a very complete series of x-ray photographs showing the wires in position and the changes undergone by the aneurysm during a period of two years. He arrived at the general conclusion that in the majority of cases there was evidence of cure, as the patients were alive and at work ten and more years after the wire had been introduced. He also appended an interesting table of cases compiled by Mr. G. H. Colt, showing the duration of life from the first recorded symptoms to the time of death in 133 men and 8 women suffering from thoracic or abdominal aneurysms. The President, Professor A. J. HALL, Professor A. M. CONNELL, Dr. A. E. BARNES, and others took part in the discussion which followed.

THE London County Council has decided to grant to the four whole-time London coroners who receive a gross salary of £1,500 a temporary addition of £300 a year, to continue until such time as the Council obtains parliamentary powers to pay coroners fixed salaries or until March 31st, 1922, whichever be the earlier date. The payment is to be conditional on each coroner submitting quarterly a certified statement as to his out-of-pocket disbursements. Out of his gross salary a coroner has to pay for the services of a deputy and of a clerical assistant, as well as for office accommodation and travelling. In the pre-war period such expenditure was computed at 25 per cent. of the total income. From figures which the coroners have recently furnished, their present out-of-pocket expenses average £400 a year.

Rebielus.

"PHENOMENA OF MATERIALIZATION."

William Crookes, Oliver Lodge, Camille Flammarion, Charles Richet, Lombroso, Morselli, Flournoy, Zöllner, Ostwald: such is the constellation of stars which shine in the firmament of spiritistic or mediumistic phenomena. Respect for the eminence of these men induces us to deal at some length with the volume entitled *Phenomena of Materialization*, a translation into English of a book written by Baron von SCHRENCK NOTZING, "practising physician" in Munich; it is a weighty tome of 340 pages, which by its endless repetitions produces a feeling akin to the hypnotic trance. Moreover, we regard it as a duty to examine and criticize the beliefs, observations, and theorizings of the human mind, so far as time and space allow; especially when a belief has reached such a stage that thousands of mankind are deriving consolation from their faith in it. When its professors allege a scientific basis for their faith, and physiology and psychology are dragged in to support it, the duty of the medical profession to inquire into the origin and methods of the cult becomes even more insistent.

The expression "materialization phenomena" is applied to the alleged production of forms and materials of organic or even inorganic matter by a so-called medium, who, it is assumed, has been deprived of the possibility of having concealed the materials about her person or in her surroundings. The manifestations are supposed to emanate from the medium—from her skin, her eyes, her mouth, or other orifices of her body. The emanations may take the form of threads, white, grey, or black, of clouds or mists, of ill-defined solid masses, of materials resembling muslin, wool, paper, or other mundane substances; hands, arms, or heads may be produced, and occasionally fully formed phantoms of distinct character and definite features and forms. In mediumistic jargon such manifestations are described as "teleplastic phenomena," as distinguished from the "telekinetic" class, which comprises the spiritists' table-turnings, levitations, raps, and "direct" writing.

In his preface Baron von Schrenck Notzing confesses that hitherto the observations of mediumistic phenomena have not fulfilled the requirements of exact scientific method, but the translator asserts that in the present work the reader has "a full scientific account of a set of strange occurrences observed under the strictest conditions of control, and as yet quite unexplained." As we have not witnessed any of the scenes we do not presume to express an opinion on the reality or otherwise of the phenomena described. But the author and his translator lay claim to the adoption of an exact scientific method, and it is with this claim that we propose to deal. Let us take first the attitude of Baron von Schrenck Notzing towards his mediums and their friends.

The medium chiefly employed was called Era C. who seems to have been 23 years of age when the sittings began in Paris in 1909, at the house of her "protectress," Mme. Bisson. The medium had had four or five years' previous experience in spiritualistic circles. At all the sittings recorded in the book Mme. Bisson appears to have been present; at several sittings Mme. Bisson was alone with the medium, and some of the most remarkable phenomena seem to have occurred for the first time at these *séances*. Our first criticism of the author as a scientific person is in this matter of Mme. Bisson. He is very angry with people who have hinted that possibly Mme. Bisson acted in collusion with the medium. "If some servants assert that Mme. Bisson's mere presence at the sittings constitutes a source of error, this shows a deplorable lack of understanding of the complicated mechanism of the mediumistic occurrences." He speaks of the "unjustifiable and insulting insinuation against this lady," and thinks that he has disposed of the criticism by stating that Mme. Bisson, "in the spirit of a purely scientific research, repeatedly allowed herself to be examined" by him. Yet on many occasions, and "during the frequent incidents of

¹ *Phenomena of Materialization. A Contribution to the Investigation of Mediumistic Teleplastics.* By Baron von Schrenck Notzing, Practising Physician in Munich. Translated by L. E. Fournier d'Albe, D.Sc. (Lond. and Birm.). London: Regan Paul, Trench, Trubner, and Co., Ltd.; New York: E. P. Dutton and Co. 1920. (Double cr. 8vo, pp. xii + 340; 225 figures. 35s. net.)

the sittings which would leave any other experimenter helpless. Mme. Bisson always finds the right means to restore the disturbed psychical and physical equilibrium of the medium." The right means apparently do not exclude entrance into the cabinet occupied by the medium. He goes on to say: "Besides, with what motive could Mme. Bisson, living in Paris, try to deceive a foreign savant for four years?" Because Mme. Bisson housed and fed the medium for three and a half years, "there cannot be the slightest doubt that Mme. Bisson has conducted the four years' investigation out of a pure interest in the subject, in the scientific exploration of the mediumistic problem." The fact that the lady has published her own observations "ouches for the authoress's bona fides"; and, again, "The imputation of fraudulent assistance is thus deprived of any reasonable basis."

With regard to mediums, the Baron admits the possibility of fraud in certain manifestations. Thus he says that "the person under test may, if the effort does not succeed at once, or if the forces available do not suffice, easily be led to assist, to some extent unconsciously, with the muscles." In both Eusapia Paladino and in Era C. the violent muscular action suggested the pains of childbirth, and are described as "mediumistic labour." "In combination with a vivid desire for success they easily lead to an unconscious mechanical execution of the task by the limbs." A medium named Mrs. d'Esperance was, the author says, regarded as an honest and credible person, and while she was believed to be sleeping in a cabinet her shadow friend "Yolande" was seized. On this Mrs. d'Esperance says: "The man who had seized her said it was I. This assertion appeared to me so extraordinary and incomprehensible that I could have laughed, if my utter helplessness and weakness had not rendered me incapable of thinking or even of moving." On this the Baron remarks: "In consequence of this shock this lady of unimpeachable character broke down completely and became seriously ill." This sympathetic attempt to defend the lady may be chivalrous, but is it scientific? In describing how the spirit "Mary," produced by Florence Cook, Sir William Crookes's medium, was seized and found to be the medium herself in a flannel dress, and corsets, the Baron does not even consider the possibility of fraud. He suggests "transfiguration," "transmutation," or pseudo-materialization as the explanation. We believe we are correct in saying that the earlier manifestations by Eusapia Paladino were so palpably unreliable that the Society for Psychical Research refused to investigate them farther. When, fifteen years later, the medium was examined again, a committee of the same society reported that, although some of the results were still as before, there were others that could not be explained. Would it, we may ask, be scientific to assert that, because some of the tricks of a conjurer are beyond our comprehension, these tricks cannot be due to deception of our senses? Surely the scientific inference is that all the effects may be produced in a like manner, but that the means at our disposal do not allow us in all cases to perceive the deception. The Baron, however, will have none of this explanation. Everything that he cannot see through must be produced by some power of which we know nothing. If it is pointed out to him that the curtains of the cabinet in which the medium has been concealed are studded with pinholes, it does not make him sceptical in the true sense of the word. He does not institute a scientific inquiry into the way in which the pinholes occurred; he sets about giving some ingenious explanation which is merely a figment of his imagination. The great difficulty experienced by our learned men with . . . is that the mediums take care that . . . of scientific investigation shall not be applied to their performances. Thus the Baron is continually afraid that an attempt to remove a portion of the materialization in the case of Era C. would lead to a serious effect on her health, or might even cause her death. So far as we can ascertain from the text, the only ground for his belief is that on one occasion an unsuccessful attempt to capture a portion of brown substance from the shoulder of the lady led to an outburst which would seem to have been of an hysterical character. We think he might have been reassured by the fact that the capture of Mrs. d'Esperance in the guise of "Yolande" did not lead to death, but merely to the discontinuance for a

long time of the sittings—not, perhaps, an undesirable result. As a matter of fact some men of science seem to throw away the whole of their scientific equipment and training when they become interested in spiritistic phenomena. The Baron urges the necessity for the combination of an extreme degree of scientific scepticism with personal benevolence to the medium. It seems to us that a benevolence which for four years tolerated what appear to be deceptions growing in audacity with practice up to the production of portraits which look to us like drawings on paper, must in the end have considerably diluted the spirit of scepticism. "If," says the Baron, "we consider it a priori impossible to protect ourselves against prestidigitation and other fraud practised by the mediums, we thereby declare the human senses to be incapable of scientific determinations of any kind." To which we reply that if a priori you assume the existence of "teleplasma," and then accept conditions of investigation which practically preclude you from checking the impression of one sense by the impressions of other senses, you have in effect rendered yourself incapable of any scientific determination at all. To sprinkle a book with apologies for the "martyrdom of the medium" because even some measure of control has been attempted surely prejudices the position, and must render nugatory any claim to the scientific spirit.

The Baron's attitude to the manifested material is curiously unscientific. Thus, in one place Era's head is covered with a white cloth. "A critic," says the Baron, "would at once have the impression that Era had put a handkerchief over her head, but . . ." and an irrelevant detail is dragged in with complete disregard to scientific investigation. The description of this sitting ends with the statement that "the medium was obviously anxious to mask herself with her teleplastic productions." Is it scientific to describe what might have been a handkerchief as a "teleplastic"? . . . all events, until it has been proved not to . . . We lean, however, that the interest of the highest possible advancement of the phenomenon is greater than the constant diversion of the medium's attention towards the control, as such control hinders the rational development of the phenomena and reduces the efficiency! This view of the pernicious effect of control doubtless accounts for the fact that the Baron made no strenuous efforts to clear up doubts which arose in his mind when he noticed on one occasion that a flat lifeless structure resembling a lady's glove had replaced the hand of the medium which was supposed to be on her knee. When the medium had reached the stage of producing pictures of faces, the Baron argues that they could not have been ordinary photographs. He fails, however, to bring into juxtaposition with this inference the fact that Mme. Bisson had a studio and was something of a sculptor. With regard to one of the pictures which showed numerous rectangular creases, as of paper unfolded, the author remarks that "anyone who does not realize the rigorous precautions taken must necessarily assume that a packet was fraudulently introduced." But the Baron amiably remarks: "So long as no such trick is actually performed under the same conditions . . . the discussion of the hypothesis 'of conjuring' seems superfluous." On another occasion the discovery on the floor of some small white particles, giving the impression of small balls of paper crushed with a shoe, is discussed as not seeming to have any connexion with the "phenomena." During most of the sances the medium is stated to have been in a hypnotic trance. This may be so; but it seems curious that while still in such a state of trance the medium should be able to come forward at the end of a séance, take off her tights, and ask for a "gynaecological" examination! However, this is a matter which we must leave to those experienced in hypnotism.

It seems to us that Baron von Schrenck Notzing effectually puts himself out of court as a scientific observer. Had he been content to refrain from all allusion to the martyrdom of mediums; had he not made clear from the outset his belief in teleplasma; had he merely recorded strictly the impression on his sense of vision of the manifestations even to the dreary length of this book; had he not tried to invent explanations for such things as the pinholes in the curtain and the paper-like apparitions; had he tried to

baroque methods for discovering the origin of the pinholes and the paper creases—had all these things happened, it might have been possible to treat his book with some respect. As it is, the production is a reproach to any man calling himself a scientist, for it neglects every condition of true scientific investigation. Instead of inquiry we have assumption; instead of impartial statement of observation we have a prejudiced attempt to fit the phenomena into a belief. When one of the investigators present at some sances ventured to state that everything was trickery, the Baron tersely remarks, "On account of this negative attitude Dr. Specht was not invited to further sittings."

Our object in dealing at such length with this book is to protest against the assumption of scientific method when no real trace of such method exists. Baron von Schuenck Notzing compares the present position of mediumistic investigation with the position in the distant past of astrology in relation to astronomy and of alchemy in relation to chemistry. But he cannot have it both ways. Scientific method has advanced considerably since the days of astrology and of alchemy. If the Baron's science has not advanced beyond the stage of astrology and alchemy, he should not lay claim to scientific method, which is something far different from the method of the astrologer and the alchemist. We recall again the names of the eminent men of science with which we began. It is excusable that an imaginative novelist permit himself to swallow any tale of the marvellous that may be presented to him. But that men of eminence in the scientific world should delude themselves into supposing that their observations of mediums resemble in the remotest degree the methods of science is deplorable. Whether mediumistic powers exist or not, the investigation of those pinholes in the black curtain should certainly precede the elaboration of "teleplastic hypotheses."

SURGERY.

HEY GROVES'S *Synopsis of Surgery*² is so well known that it needs no introduction when, as a new edition, it makes its bow for the fifth time. This alone is sufficient proof that there is a need for a book of the kind, and if one must have a "cram" book, then this is just about as good as it is possible to have. We believe its popularity to be deserved. The previous edition was reprinted three times during the war, and the author has taken advantage of a new edition to incorporate in the text some of the more important lessons the war taught. Knowing Mr. Hey Groves's predilections as we do, it does not surprise us that the chief additions have been made to the section on fractures. The section dealing with blood transfusion is good, the choice of donors and technique being well covered in a very condensed but lucid form. In a book of this type any surgeon particularly interested in a special subject will easily be able to find fault. It is not intended to be a book for specialists, but on the whole we believe that the information which it gives the student is sound. A few line drawings are added to the new edition, and the surface anatomy figures have been partly coloured.

Mr. IVOR BACK and Mr. TUDOR EDWARDS contribute the book on *Surgery*³ to the "Students' Synopsis Series" of Messrs. J. and A. Churchill. The work is intended to help the student to revise his work and not to supplant his textbook. It is addressed to the less industrious student, and it is possible that he may find it useful.

Dr. ARCHIBALD McDONALD, of the Johns Hopkins University, is to be congratulated on his *Essentials of Surgery*⁴—a volume intended for probationers and nurses, and in most respects a thoroughly good book. The whole ground is well covered, and the descriptions of the various diseases which come within the purview of the surgeon are clear and concise. The nurse whose privilege it is to listen to a course of lectures based on this manual will be fortunate. At the end of each chapter is a list of suggestions for

illustrating the chief points. The book evidently does these things for us, for we note that after the text we are advised to demonstrate and serious layers "on anatomic animal." The method of teaching selected cases and case histories is to be employed widely. The only drawback, extremely "dry" appearance, due entirely to the type on the page and the kind. There is a valuable glossary at the end.

SYPHILOLOGY.

In the second edition of Dr. LLOYD THOMPSON'S *Syphilis*,⁵ the subject has been brought thoroughly up to date. It has, moreover, been treated in a comprehensive manner, for, as the author states in his preface:

"Syphilis is no longer to be considered a genito-urinary disease, nor a dermatological disease, nor a disease belonging exclusively to any speciality, but is to be thought of as a disease requiring knowledge in all fields of medicine."

The question of visceral syphilis, which did not receive much notice in the previous edition, has been amplified, and an excellent bibliography of the literature of the subject is appended for the use of those requiring further information. In order to render the work as practicable as possible, special attention has been given to diagnosis and treatment. The chapter on laboratory diagnosis has been enlarged, for laboratory aid is more important for successful treatment in syphilis than in any other disease. We regret that the description of the technique employed in the examination of venereal sores for the presence of the *Treponema pallidum* has not been rendered still clearer by the addition of diagrams and micro-photographs. Although illustrations are given of the organism of syphilis demonstrated in the tissues by means of various staining methods, there are no plates to assist the reader in distinguishing the *Treponema pallidum* from similar organisms under dark ground illumination. Chapter VII contains a full description of complement-fixation tests and other aids to diagnosis. Since writing his previous edition the author has apparently lost faith in the luetin reaction.

Chapter IX deals with the disease from the public health point of view. In the author's opinion education should not stop at the teaching of the dangers of venereal disease, but should include dissemination of knowledge of methods of personal prophylaxis.

"Free prophylactic treatment for both men and women should be advertised in all cities, where it may be administered, but instructions for prophylaxis and prescriptions for the necessary materials be furnished."

With the objections of the moralists against such an arrangement he has little patience, believing that the fact that the disease is as likely to affect the innocent as the guilty is sufficient justification for adopting any methods of prevention likely to meet with success. Useful sections are included on the important subjects of standards of cure, and of syphilis and marriage. In the paragraphs dealing with the latter the dictum is laid down that no permission to marry should be given unless the Wassermann reaction is negative. The complete absence of clinical symptoms over an extended period is, in the author's opinion, insufficient justification for marriage with a positive Wassermann reaction.

Dr. Thompson is an advocate of intrathecal medication in all cases of neuro syphilis. The technique he employs is a modified Ogilvie method, the injections being given at intervals of seven to ten days.

"The intraspinal treatments should be continued until the spinal fluid becomes negative, or, in the case of paretics, for eight or ten injections if no objective or subjective improvement is noted. . . . If intraspinal treatments do not relieve cerebral symptoms, intracranial, either subdural or intraventricular injections, should be given a trial. No case of syphilis, from the chance to paresis, should be given up until all means of treatment are exhausted."

² *A Synopsis of Surgery* By E. W. Hey Groves, M.S. M.D., B.Sc. Lond., F.R.C.S. Eng. Fifth edition. Bristol: John Wright and Sons, Ltd. 1920. (Pp. 810 pp. 623; 13 plates, 21 figures. 15s. 6d. net.)

³ *Surgery* By Ivor Back, M.A., M.B., B.C. Camb., F.R.C.S. Eng., and Tudor Edwards, M.A., M.C. Camb., F.R.C.S. Eng. Students' Synopsis Series. London: J. and A. Churchill. 1920. (Pp. 483. 15s. net.)

⁴ *Essentials of Surgery*. By Archibald McDonald. Philadelphia: J. B. Lippincott Co. 1920. (Pp. 483. 15s. net.)

⁵ *Syphilis* By Lloyd Thompson, Ph.D., M.D. Second edition, thoroughly revised. 1920. Philadelphia and New York: Lea and Febiger. (Med. 8vo, pp. 225; 81 figs., 7 plates.)

the sittings. It includes with chapters on congenital syphilis. Helpless it is a remarkably complete work, and one in which practical matters, rather than points of academic or historical interest, have been emphasized.

NOTES ON BOOKS.

WILLIAM SUTHERLAND, whose interesting biography has been attractively sketched by the Professor of Physiology in the University of Melbourne, Dr. W. A. OSBORNE,⁶ was an independent worker in the realm of advanced physics and never held any professorial chair. The great majority of his sixty-nine contributions to scientific literature, given in an appendix, are on physical problems, and many of these appeared in the *Philosophical Magazine*; but there are some on physiological subjects, such as the rate of the propagation of the nerve impulse, the chemistry of globulin, and the heat coagulation of protein. In addition, he did much to popularize recent science by writing in the lay press, and thereby advocated wise reforms in many directions, such as education, the position of women, abatement of the dust and smoke nuisances, and the beautification of Melbourne and the Yarra. Unfortunately he did not live to see the electrification of Melbourne's big suburban traffic, of which scheme he has more claim than any politician to be called the father, nor the utilization for power of the huge deposits of Victorian brown coal which his mental vision clearly foresaw. Possessed of an encyclopaedic knowledge, he was characteristically modest and honest; thus he refused all honours, and when approached for his assent to be nominated for the Royal Society, he sent the rather disconcerting reply that the proceedings and transactions of the Society were available in Melbourne, and that he was unaware of any other advantage attaching to the Fellowship. In fact he somewhat resembled Tyndall, and was usually much sunburnt from exposure in the bush, in which he delighted. He chose a small income and an independent position, and after his sudden death his biographer comes to this conclusion: "Among the saints of science high place will assuredly be found for William Sutherland."

Dr. R. S. CARROLL'S *The Soul in Suffering*⁷ contains five-and-twenty chapters written, as the author tells us in the preface, "with a constructively sympathetic understanding of the soul-need which comes to the suffering." Here the reader will find lay sermons, the commonplaces of consolation, set out with a magniloquence of philosophical and otiose verbiage, reinforced with quotation, analogy, and inextinguishable optimism. The book will doubtless find many readers, and should prove more helpful to sufferers than even the blessed word Mesopotamia.

⁶ William Sutherland: *A Biography*. By W. A. Osborne. Melbourne: Lothian Book Publishing Co. 1920. (Cr. 8vo, pp. 101; 4 illustrations. 7s. 6d.)

⁷ *The Soul in Suffering. A Practical Application of Spiritual Truths*. By Robert S. Carroll, M.D., Medical Director, Highland Hospital, Asheville, North Carolina. New York: The Macmillan Company. (Post 8vo, pp. 211. 8s. 6d. net.)

ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

THE Council of the Association of Certifying Factory Surgeons has recently drawn the attention of the Chief Inspector of Factories to two matters which are considered to be of considerable importance to certifying surgeons.

The first is the circumstance that, in connexion with the two last annual reports, they have not been asked to include any particulars respecting the allowing of conditional employment (Section 64 (5) F. and W. Act, 1901), but have simply been required to give details respecting "rejections." Section 122 (6) F. and W. Act, 1901, requires a record of all young persons ascertained by medical examination to be physically defective, and of the action taken by the certifying surgeon with respect to such. The word "results" is used, and as this signifies more than rejections, it is held that a return confined to these cannot cover the obligation. The system of conditional certificates, in spite of its imperfections, is regarded as having greatly extended the usefulness of the certifying surgeon, and as being of proved benefit to large numbers of young people on commencing their industrial career. Apart, therefore, from the strict legal requirement, it is

considered of public interest that a full record of the "results" of factory medical examinations should be available. It has been pointed out that the action taken by the certifying surgeon, as a result of the defects found, depends, as a rule, more on the nature of the industry and its capacity for providing suitable alternative employment than on the nature of the bodily disease or infirmity *per se*, so that any particular defective may be totally rejected at one factory and certified conditionally at another; that the bulk of defectives may be regarded as of one class, dealt with in two different ways according to varying circumstances; that the incomplete return at present asked for cannot possibly give any idea of the discrimination exercised in dealing with these young people, and is therefore unfair to the surgeon as well as misleading to the public. Whilst the former publication in the Chief Inspector's annual reports of a complete summary of conditions attached to certificates of fitness is regarded as having undoubtedly served a useful educative purpose, in view of the labour entailed in compiling the table, the association does not press for its renewal. On the other hand, the Council suggests that a full classification of all those found affected with disease or bodily infirmity should be published under two divisions—namely, (1) rejections and (2) certified conditionally.

The second point is what the Association of Certifying Factory Surgeons considers to be the incomplete and unsatisfactory methods adopted in the effort to secure adequate first-aid treatment of the injured in those factories and workshops where provision for such is obligatory. The Council is convinced that no arrangements can be considered efficient unless placed under some system of regular medical supervision. It is the opinion that a satisfactory control of first-aid and ambulance arrangements could be readily obtained by making it an obligation upon the employer to obtain from the certifying surgeon—every three months in the case of works employing 500 hands or over, and every six months where under 500 are employed—a certificate to the effect that the provision made is suitable and sufficient. The Chief Inspector has been asked to consider the advisability of authorizing a medical representative of the department to discuss this matter with expert representatives of the association with a view to some practical scheme being evolved.

NOTE-TAKING IN GENERAL PRACTICE.

[FROM A CORRESPONDENT.]

IN reply to one who had expressed some dissatisfaction with the opportunities offered by general practice for the study of disease, and envy of the opportunities of the specialist, Sir William Gowers wrote:

"Cases which come under the notice of the physician and are instructive in detail are very few compared with the immense number which are seen only by practitioners, and the opportunities these present are wholly lost for want of a little careful note-taking and the knowledge of what to observe. Moreover, practitioners have the opportunity of doing what no one else can—following up cases and observing their course. This is of extreme importance after careful record."

This opinion is worth as much to-day as it was when given twenty-five years ago, for no one will dispute that careful note-taking is essential for both the science and the practice of medicine; it is valuable not only to help the attendant's memory, but to save his time. How much quicker to learn, how much more accurate, a patient's medical history that was recorded at the moment by the medical man in attendance at previous illnesses, than what can be dragged out or sifted from what pours out of a patient's memory of his past miseries.

And what is the time occupied in taking these notes? No more than that required to make the necessary careful inquiries; and the busier one is the more need is there to take notes, because with the rush of patients it is more difficult to remember the details of each case and because when one has previous notes to refer to less time need be taken in catechizing the patient. If there is not time to take notes, there is not time to see patients properly, and something is at fault either with the method or the means.

The Value of Records.

Any medical man who has kept the simplest notes of his cases must realize their value to himself, and conversely, how often must many have longed for such a record however brief!

It is suggested that notes such as the busy general practitioner can take will themselves be valueless, because it is not possible to name accurately most illnesses, that they will merely be notes of signs or symptoms and not interpretations of them, but surely this will be their true value. Clinical notes that are statements of fact must have greater scientific value than mere opinions: they will be of value not for adding up in rows, but for reference, research, and discussion. Even the interpretations of these signs and symptoms, under the heading diagnosis, will be of value if we realize that the term used represents not a disease but a condition.

It should be realized that the value of a clinical history often lies in the collection of many small details rather than in the record of any one big event; one small detail may be sufficient to make the evidence complete. Without the correction supplied by such records of fact, ill-founded opinions are apt to grow in a man's mind and to prejudice his views. The making of a note, however simple, if one has in mind at the time that the object of that note is future reference and help for one's self or someone else, must tend to make one think more and take more care; true it is often by no means an easy matter to find words in which to express symptoms and opinions, but the habit of doing it frequently and having to do it carefully should in time develop a better practice.

The special value of a general practitioner's record lies in the fact that he alone can see the whole of a disease from the very beginning, knows the conditions that existed before the beginning, and knows the life-history of the patient; he sees those beginnings of disease that, contrary to expectation, do not develop beyond a certain stage; he sees those diseases that are not fatal, though according to precedent they should be, and those conditions that develop into serious and fatal diseases when they are not expected to.

Note-taking and Research.

There are two types of clinical research, and the note-taking required for each is different. There is that advanced and detailed research such as is carried on at the St. Andrews Institute for Clinical Research under the direction of Sir James Mackenzie, which requires specially apt and trained observers. The other is that which may be conducted by the general practitioner.

In a report of the Medical Research Council (BRITISH MEDICAL JOURNAL, January 15th, 1921, p. 91) occur these words:

"There are many problems in medical science which can best be studied, and some indeed which can only be fully studied, the Council believes, by men engaged in professional practice, who are in a position to follow the signs and results of disease and the effects of given treatment in suitable cases from their earliest to their latest phases. Studies, however, of this kind can only be successful if the professional man has some leisure and if he has access at need to laboratory and other resources, like those of a well-equipped hospital."

If these words do not apply to the family doctor, I do not know to whom they can. True the last sentence is not appropriate to the average general practitioner of to-day, but the Ministry of Health, or at any rate its Medical Consultative Council, has by its interim report shown the way and the desire to provide this opportunity for the general practitioner.

However, though much investigation can only take place in the conditions pertaining to an institution, it is important that disease should be studied in what one may call its natural surroundings, otherwise we cannot estimate properly the influence of these surroundings, and unless we know how this influence affects cause and progress, we cannot hope to find the means for prevention and cure.

This general practitioner type of investigation is of great, though varying, value; a medical man must, from his training, be competent to take notes, but practice and experience, interest and appreciation, will increase the value of his work. Whatever he may have been taught in hospital by his clinical lecturers, he yet must learn for himself the methods best suited to his practice, and he may learn much by comparing, when opportunity offers, the methods adopted by others.

The last thing wanted is a stereotyped method; that system and method will be the best which has gradually developed by a process of evolution and selection. Though in note-taking all depends on the "how," it will always be of prime importance to select the essential and the potentially useful. Facts must always be of more value than opinions, though the latter will often be worth much; the difficulty is to differentiate the opinion that is the result of long and careful observation and deduction from that which is founded on prejudice, inaccurate observation, and insufficient knowledge.

A mere statement of an incapacitating cause such as will do for a certificate of inability to work is not likely by itself to be of much value as a clinical note; the ideal clinical note will, if possible, contain something to indicate the pathological condition, the part affected, and the cause. For instance, "indigestion" by itself will not be very valuable, but "epigastric pain two hours after food," may be useful. Compare "rheumatism" with "arthritis, left knee, traumatic," or "arthritis, right wrist, wasting muscles hand and forearm, carious teeth."

The note-taking habit will surely be an incentive to all sorts of investigations, and it is very likely to stimulate particular interest in one or more special subjects, leading the way to that ideal specialism which is the outcome of special aptitude, interest, and opportunity, in a practitioner experienced in all branches of his work. Those specially interested in any particular part or parts of their work might with advantage keep a small subject index.

Fields for Investigation.

Records as to the results of some treatment would often do much to prove its use or uselessness and to prevent those generalizations which are so frequent and harmful, and exaggerated deductions from a few failures or a few successes. How useful, for instance, would be a record of every case of thyroid disease—the early history, heredity, water supply, progress and result of various treatments; every general practitioner in some neighbourhoods would in a few years have a wonderfully interesting collection, and if he and his neighbours would one day collate and compare these notes and deductions, they could hardly fail to draw up a valuable report. Or supposing that the carefully recorded life-histories of a large number of cases of cerebral haemorrhage were examined, how interesting and possibly surprising might be the findings as regards their relation to heredity, diet, dental defects, blood pressure, kidney disease, surroundings, and occupation. What opportunities there would be for learning more of the early history of phthisis, or the after-history of the so-called pre-tuberculous patient. Again, statistics of a sort might well be considered, such as the duration of incapacity from certain diseases and accidents, and the effect of surroundings on that duration of incapacity.

A medical man who notes the signs, symptoms, and treatment of his cases and their sequels at intervals during the patient's life, will accumulate a mass of facts for consideration and discussion with other men who have done the same, and with men who have made special study of particular diseases. It would not only add interest to work, but greatly increase its value, if this were done more or less systematically.

The members of a medical society or of a Division of the British Medical Association, might arrange a series of subjects of general interest which they would discuss at given dates—say in two, three, or four years' time, or even at longer intervals—one or two subjects being chosen for each year. Or such a scheme might be widened in its area and applied not to one or two medical societies only, but to the whole of England; and at suitable intervals, after consideration at various local meetings, these subjects might be discussed centrally at the Royal Society of Medicine, or the annual meeting of the British Medical Association.

There are all sorts of questions having local interest that might be considered, not only the life-history, causes and treatment of different diseases, but the incidence of disease as affected by occupation, general conditions, heredity, etc. Such consideration, based, of course, on the records made by those taking part, would take place first by individuals and then by groups. This would add much interest to the medical man's life, raising what may be mere drudgery to a delightful occupation; no doubt we might have to wash much gravel to find a few diamonds, but the reward is worth the work.

Sir John Lubbock wrote: "The most important secrets of Nature are often hidden away in unexplored places; many valuable substances have been discovered in the refuse of manufactories." Twenty thousand medical men in daily practice: what an enormous amount of clinical evidence and experience they must have! We need give all our thought, not to preventing its preservation, but to devising means to make the best use of it.

At the Third International Labour Congress, to be held at Geneva in April, the following medical subjects will be discussed: Protection against accidents, sickness, and old age; disinfection of wool contaminated by anthrax bacilli; prohibition of the use of white lead in the painting industry; prohibition of the employment of persons under 18 as firemen or stokers, and obligatory medical examination of children working on board ship.

SATURDAY, MARCH 19TH, 1921.

THE NEW EPIDEMIOLOGY.

WE recently summarized the report of the Ministry of Health upon the pandemic of influenza, and it may interest some of our readers if we attempt to characterize certain ways of thinking which parts of the report illustrate.

A few years ago Dr. Hamer, more in anger perhaps than in sorrow, identified epidemiology with the Sleeping Beauty and bacteriologists with the authors of the spell. This, no doubt, was to go a little too far; the Sleeping Beauty has never been actually comatose; Dr. Charles Creighton was applying stimulants even before Dr. Hamer took the case into his very efficient hands. Yet it is at least certain that, down to a very recent date, the bacteriologist's views upon the etiology and prophylaxis of epidemic diseases were regarded in all the "best circles" as of much greater importance than the views of any other medical or non-medical investigators. Even now a considerable majority of medical men and nearly all laymen are realists. They demand to be shown something on a plate—a Petri plate—and to be told "this is the germ which causes the disease." The next step is either to exterminate the germ or devise an antidote. This step having been taken, the epidemic disease—by definition due to the germ—is, or ought to be, of only historical interest.

But orthodoxy has now to reckon with heretics. As generally happens, the heretics won their first successes through the mistakes of the orthodox and in virtue of their own audacity. On the one hand bacteriological realists drew too many bills on futurity which were not honoured on presentation, and again they did not always *seem* (as Dr. Hamer was never weary of pointing out) to agree perfectly one with another. On the other hand, they ruffled the feelings of a small but pugnacious group of statisticians, who, having acquired a technique at least as mysterious, and therefore awe-inspiring, as that of the immunologist, declined to be snubbed. The consequence is that a "new" epidemiology if still schismatic has at least some chance of acquiring orthodoxy. At first blush this new faith is not attractive; it is so easy to parody. The outraged realist proclaims that one of the "new" epidemiologists believes influenza to be not only influenza but everything else, and holds that a sufficient answer to criticism is to invoke the name of Sydenham with rapture; that another sees life as a monomolecular reaction and disease as terms of a Fourier expansion; while a third, emulating Hudibras and able to

"Resolve by sines and tangents straight,
If bread or butter wanted weight;
And wisely tell what hour o' th' day
The clock does strike, by Algebra."

is still not quite sure that anything has been added to knowledge (except by statisticians) since Galen.

But it would not need the author of *The Elephant in the Moon* to handle the orthodox school at least as severely. While, as we have surmised, the opportunity of the "new" epidemiologists was afforded them by the over-confidence of the old epidemiologists, it is due to something more than they maintain, and

seem likely to extend, their ground. They all, whether they deal in terms of medical history, of physical chemistry, or of coefficients of correlation, agree in two fundamentals. The first is that it takes something more than a bacillus to bring into being an epidemic disease. The second is that those other factors, whether inherent in the structure of man or implicit in his environment, are capable of measurement and their conjoined effects capable of prediction. It is an easy thing to sneer at the man who loves to pore over the books of those who died in ignorance of our modern lights. It is easy to rail at the attempt to number and count the phenomena of life and to laugh at presumption which will essay to foretell the succession of diseases:

"How do they call him? The sagacious Swede
Who finds by figures how the chances prove,
Why one comes rather than another thing."

But it has been by these means that all other sciences have developed, and we cannot doubt that in this way also knowledge of epidemiology will pass from a crude empiricism into a branch of exact science. No grosser mistake can be made than to confuse the familiar with the known. The relation between poverty and disease is familiar, but it is not known. For these and many other reasons, the attempt of the "new" epidemiologists to collect materials for the compilation of an exact natural history of disease, not narrowly restricting their field nor inquiring too particularly as to the specific differentiae of the disease, is, we believe, well directed. To resume the task of Sydenham armed with the tools which more accurate means of collecting and analysing data provide, is not a work of supererogation.

FINE ADJUSTMENTS.

IN his Association lecture to the Edinburgh Branch, published this week, Dr. Haldane recurred to a doctrine a particular application of which he had briefly discussed in a lecture printed in our columns of July 19th, 1919. In that lecture, dealing with the causes, symptoms, consequences, and prevention of anoxaemia—a condition in which the supply of oxygen to the tissues is insufficient—he marvelled at the extraordinary fineness of the adjustment determining the degree of activity of the respiratory centre. As he then pointed out, the haemoglobin in human arterial blood is nearly saturated with oxygen; in addition to this chemically combined oxygen a very small amount is present in free solution in the blood, and as the blood passes round the circulation this free oxygen is continuously given up to the tissues and replenished at the expense of the oxyhaemoglobin, the latter recovering its full complement in the lungs. In order that the normal state shall be maintained, the respiratory centre must be in a state to respond to its normal stimuli, the breathing must produce sufficient ventilation of the lung, the alveolar epithelium must be in good order, the circulation must be effective, and the haemoglobin normal. Investigations made during the war showed that irregular distribution of air in the alveoli, owing either to shallow breathing or to irregular obstruction of bronchi, was an important cause of anoxaemia; though some alveoli are over-ventilated, others are under-ventilated, and the net result is that the mixed arterial blood is insufficiently saturated with oxygen. The anoxaemia, not only of bronchitis, of emphysema, and of cardiac disorders, but, it would appear, of pneumonia also, is mainly due to this irregular distribution of air in the lungs, a fact which accounts for the

striking effects of the continuous administration of oxygen in the manner described in the earlier lecture. It explains also how it comes about that on the occurrence of the crisis in pneumonia the rapid shallow breathing ceases, though the consolidation remains. It might have been supposed that arterial anoxaemia must result from a large amount of venous blood passing through the consolidated lung without being oxygenated, but, as the clinical observation last mentioned indicates, and as Professor Meakins has shown by x-ray photographs of injected lungs in pneumonia, the circulation in the consolidated parts is almost entirely blocked.

The main topic of Dr. Haldane's Edinburgh lecture, however, was, as has been said, the quite extraordinary accuracy of the adjustments in the living body. He illustrated this further by a relation of some recent observations on the regulation of the renal excretion. The kidneys like the lungs regulate the composition of the blood. When a large quantity of water is ingested the response of the kidneys is so immediate that if the body is already fully supplied with water, only an extremely small dilution of the blood is produced—a dilution so small that special methods of great delicacy must be used for its detection. By withholding water the excretion of urine is diminished, and the body weight may thus be reduced by several pounds; when water is again taken freely the body weight rises, but so soon as the normal is reached any more water ingested is promptly excreted. There is thus a well defined normal threshold for water in the blood beyond which it is excreted; the use of the word "threshold" to express the stage or level at which some change occurs is happy and its application to the ratio of water in the blood picturesque. A threshold may be raised or lowered by disease, and the modern treatment of diabetes depends largely upon the recognition of the fact that the threshold for sugar which has been lowered may, by suitable dietetic treatment, again be raised. So also in respect of the maintenance of the alkalinity of the blood there is a very well defined threshold below which acid urine is excreted, while above it the urine is alkaline. It is easy to see how ideas of this order will help to an understanding of what is happening in disease, and, it may be hoped, to more effective treatment.

Some of the observations on the regulation of blood composition related by Dr. Haldane have not hitherto been published, and they will, we believe, be read with great interest. He and Dr. Douglas devised a method of investigating the gases of the mixed venous blood returning to the heart in man; by its use they found that during complete rest mixed venous blood is not only very steady as regards its gas content, but considerably less venous than has hitherto been supposed. They found also that the rate of the general circulation is faster than formerly calculated, so that a volume of blood equal to that in the whole body passes through the heart about every thirty-five seconds, or nearly two gallons in a minute. The manner in which the amounts of oxygen and carbon dioxide present in the general venous blood are maintained at constant levels is another striking example of accurate regulation.

We are so familiar with the fact that it is the nature of a living organism when deranged to return to the normal that we have ceased to wonder. If we see it in the striking adjustment which immediately takes place on over-exertion we see its slower operation in disease; it is, in truth, the *vis medicatrix naturae*. The investigations Dr. Haldane describes help us to understand how this healing force acts, and therefore how Medicine can hope to remove

obstructions out of its way, but they do not explain what that force is. We cannot now attempt to follow Dr. Haldane in the speculations lightly referred to in his lecture and more fully set out in his recent book.

LORD MOULTON OF BANK.

LORD MOULTON, known far and wide when Mr. Fletcher Moulton as a great patent lawyer, died in his sleep after a busy day on March 8th, in his 77th year. He became a judge of the Court of Appeal in 1906, and Lord of Appeal in Ordinary in 1912, in which year he received a life peerage; for his services during the war he received the K.C.B. in 1915, and the G.B.E. in 1917. He was a Fellow of the Royal Society, and the distinction was not merely complimentary. We are indebted to Sir Walter Fletcher, F.R.S., Secretary of the Medical Research Council, for the following estimate of Lord Moulton's great service to science: The biographical notices of Lord Moulton of Bank which have recently appeared in the press have hardly done justice to his scientific abilities, and have almost wholly failed to recognize his personal contributions to the *welfare and progress of medical science*. No doubt this is to be explained in large part by his sudden and wholly unexpected death, which allowed little time to current journalism for the examination of the public and private work he did in scientific fields outside his long and distinguished professional career during peace, and apart from his special services to the country during the war as Director-General of Explosives Supply. Yet the lustre of his more familiar achievements at the Bar, on the Bench, and in the Ministry of Munitions, should not be allowed to obscure the brilliance of the service he gave at every opportunity to the best interests of British medical science. He followed with close interest all the chief developments in the growing branches of physiology and pathology that contribute to medicine, not in vague and desultory admiration, but in steady pursuit and appreciation by a mind subtle, highly trained, and well stored. For the intellectual pleasures thus received he repaid the general cause of medical research by numerous and willing services of his own. Any science must gain if it has the steady sympathy of a man filled with expert knowledge of its methods, its results and its needs, who occupies a high public position. Few public and powerful men have even elementary knowledge of any natural science, and fewer know the roads by which all sciences advance. Lord Moulton in unnumbered ways was able to help the medical sciences by his advocacy and his influence, and to enlarge the general appreciation of them. He gave direct help besides to many special medical causes. He was much concerned, for instance, in the development of the inoculation department at St. Mary's Hospital, and Sir Almroth Wright has acknowledged his debt to Lord Moulton for some at least of the "phylactic" terminology now current in the study of the protective responses of the body to invasion. In particular it will be remembered how valuable and widely effective was the evidence given by Lord Moulton before the Royal Commission upon animal experiments—perhaps one of his most brilliant pieces of pleading. In this he irresistibly exposed the essential cruelty of those who, by opposing animal experiments, were impeding the diminution of the total sum of animal and human suffering. It was largely in recognition of his many services to medical science that he received his honorary doctorate at Cambridge on the occasion of the opening of the new School of Physiology by H.R.H. Prince Arthur of Connaught in 1914. In 1913 Lord Moulton was appointed to be the first Chairman of the Medical Research Committee (now Council), and he held that office until 1916, when he was led to retire by his increased duties in the Ministry of Munitions. He maintained up to the last the keenest

personal interest in the work of the Council. During the first critical year of its existence the Committee held weekly meetings in his house, and under his guidance laid down the broad principles upon which that new venture in the relations of science to the State was to be guided. It is well known that he brought to this work by no means only the general authority and support of the lay chairmanship commonly expected from an eminent man set to preside over a committee of experts. His familiarity not only with the content of scientific knowledge, but also with the daily realities of the laboratory and of the ward, greatly enriched and steadily guided his influence. This may perhaps be traced especially in the success with which that early committee approached certain vital problems that seem now in retrospect to be less formidable, perhaps, than they were at that time and until the war had brought home to the country the place and power of which research work should have been possessed long before. Among these may be mentioned the problems of obtaining reasonable security of tenure for scientific workers, and Ministerial approval for it, when the only available funds had nominally only an annual sanction; or, again, of widening the scope of reference to "medical research" so as to include that work in primary sciences for which much of pathology waits in need, and from which strictly utilitarian results in the long run may be expected with more confidence than from direct frontal attacks upon particular morbid processes by *ad hoc* research. For all these services of his to medical science, though they were but the parerga of a crowded and laborious life, the medical profession must always lie in heavy debt to Lord Moulton. Personal dues of affection and regard are owed to him by many individual members of the profession and by many scientific workers, who drew encouragement and inspiration from the subtle play of his critical insight, given freely in private talk or emerging with easy opulence among the catholic charms of his remarkable conversational powers, never shown more effectively than in the circles he delighted in drawing together to enjoy his genial and unmeditated hospitality.

AIR AMBULANCES.

IN the JOURNAL of December 13th, 1919 (p. 785), we recorded the views of the famous French surgeon, M. Tuffier, on the value of aeroplanes in military surgery, arising from his experiences on a professional visit to see a wounded French general in Southern Morocco. The patient had been brought by aeroplane for surgical treatment from a distant outpost over the middle Atlas mountains and over regions occupied by hostile tribes to a hospital in a large military station. In the south of Algeria and Morocco and in the Sahara the French army, owing to the conditions of the country and the nature of the military operations, had been led to make considerable use of aeroplanes for the transport of the wounded also. M. Tuffier was shown a machine specially constructed for conveying two wounded men, but it was not found very satisfactory, owing chiefly to the difficulty of lifting the patients in and out of the fuselage. The French military authorities have been giving careful study to the designing of special aeroplanes for transporting wounded, which would be of particular value in such frontier operations as those in their African territories. The Canadian Army Medical Corps also made some experiments in designing a similar aeroplane, but we have not seen a report of their result. Nearly three years ago the Medical Department of the United States Army undertook to prepare plans for the construction of air ambulances. Messrs. Vickers, Ltd., have now, we learn, constructed an aeroplane ambulance, modified from the "Vickers Vimy Commercial" type of aeroplane, which seems to be a great advance on anything that has previously been achieved. This machine is capable of carrying a crew of two, two attendants (for

instance, one doctor and one nurse), and four stretcher cases or eight sitting cases, at a speed of 109 miles an hour for five hours, without a stop. Two Napier "Lion" engines of 450 horse-power each are installed, and all parts of the aeroplane, other than the fuselage, are interchangeable with the ordinary service type "Vimy." The two pilots are accommodated side by side in the pilots' cockpit in the nose of the aeroplane. The stretchers are fitted on one side of the cabin so that there is adequate clearance space, and the stretcher racks can be folded up out of the way when seating accommodation is required. Medical equipment up to 105 lb., stores to 200 lb., and a water tank for medical purposes holding 165 lb., are also carried, as well as the engine necessities. A wireless equipment is provided; there are special cooling arrangements for tropical climates, and adequate lavatory accommodation is provided. Under the pilot's seat in the front of the cabin there is a door which allows of the loading and unloading of the stretchers, so that the possibility of congestion, and turning of corners and similar rough treatment of the patients, is eliminated, while further door space is provided for rapid evacuation in case of emergency. The lessons of the "side-shows" of the great war must not be forgotten, and in the military reorganization of our African colonies, Mesopotamia, and India there is a wide field for the employment of ambulance aeroplanes, which could effect large economies by cutting down the number of outlying military hospitals at present necessary. The excellent photographs of the Vickers aeroplane ambulance that we have seen suggest that it provides a most comfortable, even luxurious, mode of transport for the wounded.

TRYPANOSOMIASIS RESEARCH.

DIFFERENCES of opinion which existed with regard to the means which could be taken to check the spread of trypanosomiasis in Africa led the Colonial Office to appoint a Departmental Committee, which reported in May, 1914. The Committee agreed that the proposed experiment of removing wild animals from a selected area might produce valuable information, both as regards the habits and the extent of the infectivity of the fly, and the degree of infection of man or stock derived from wild animals. The Committee, however, laid more stress on the need for further investigation. The outbreak of the war prevented any action being taken on this report, but the increase of sleeping sickness in certain of the French equatorial colonies and also in the Belgian Congo led the French Société de Pathologie Exotique to appoint a committee under the presidency of M. Laveran. The report of this committee, which was adopted by the French Colonial Minister, attached particular importance to the administration of atoxyl, with the object of destroying the flagellates in the blood of all infected cases. This, it was recognized, would involve a large personnel in all infested districts to detect and treat the infected. Though the extermination of *Glossina* was regarded as impossible, it was thought that something could be done to remove the natives from areas chiefly frequented by the fly and to protect them against bites. At home the Secretary of State for the Colonies applied to the Imperial Bureau of Entomology, which appointed a special *Glossina* Subcommittee. The report of this committee begins by observing that the tsetse flies of the *Glossina morsitans* group range over very wide areas of tropical Africa. In Southern Rhodesia, where the fly-belts are comparatively small, their extent has been estimated at 9,000 square miles. In Northern Rhodesia it would, it is said, be difficult to find a continuous area of fifty square miles free from *G. morsitans*, except on the plateaus. Probably more than a fifth of Nyasaland is infested by tsetse flies, and the fly-belts cover nearly half Tanganyika territory. The need for more knowledge of the habits and life-histories of the flies and of the factors which favour their increase or inhibit their spread is insisted upon; even in

respect of *G. morsitans* there are many important gaps in knowledge, while practically nothing is known about *G. pallidipes* and *G. longipalpis*. Of the methods suggested for the eradication of the tsetse flies, the five principal are: wholesale destruction of the larger mammals; the clearing of all small trees and undergrowth; the continuous capture and destruction of the flies on a large scale; the eradication of natural breeding places, and the provision of artificial ones from which the pupae would be regularly collected, the flies emerging from them being killed and any parasites released in order that they might be bred on a large scale. All these proposals are condemned on the ground that it is impracticable to carry them out effectively over large stretches of country, though they might be effective in limited areas, as seems to be proved by experience in the island of Principe in the Gulf of Guinea. The report emphasises the necessity for further study of the bionomics of the insects and more thorough surveys of the areas. The report was discussed at two meetings of the Royal Society of Tropical Medicine last autumn. Professor Warrington Yorke, who introduced the discussion, criticized it from several points of view; while he held as strongly as the subcommittee that further investigation was necessary, he pleaded for concentration of effort, urging that the work of entomological, medical, and veterinary research into the trypanosomiasis problem should be combined under one central organization in Africa, and be supported by contributions from all African states interested. Professor Yorke maintained that the personnel of an investigation commission should be large enough to ensure continuity of work, and that it should have sufficient funds to allow of the employment of adequate native labour for investigations on a sufficiently large scale, especially as to the dependence of fly and trypanosomiasis on game. Professor Yorke's views came in for a good deal of criticism during the discussion. Dr. Guy Marshall, one of the members of the subcommittee, maintained that it would be better to establish experiment stations in a number of different parts of Africa rather than to concentrate all efforts in one place; there were at least four species of flies of major importance, and the life-histories of each required further elucidation, as did also the influence of varying local conditions on them. Dr. Marshall also defended the committee for looking at the matter mainly from the entomological standard. The conclusion that the subject must be studied from every point of view, the medical being as important as the entomological, would seem to be the chief outcome of the discussion.

HYDROCEPHALUS IN ACHONDROPLASIA.

THE large head of the achondroplasiac has been long recognized as characteristic, forming a vivid contrast with the short arms and legs and stunted stature which complete the picture. Post-mortem examinations of the skull have revealed a tri-basal synostosis, resulting in shortening of the cranial base, with consequent brachycephaly and recession of the bridge of the nose. This smallness of the cranial base does not in itself account for the largeness of the head. Dr. W. E. Dandy¹ points out that the enlargement of the cranial capsule is not relative but absolute, the heads of these people being of the hydrocephalic type. He notes that whilst accounts of the architecture of the skull in these cases are not lacking, practically no attention has been paid to the condition of the enclosed brain. It has, however, been noted previously that the intellect of these persons is inversely proportional to the circumference of the skull. Jansen,² whose work on achondroplasia is well known in this country, has actually noted hydrocephalus in two cases. Dandy's interest in the subject was stimulated by a

patient in the Johns Hopkins Hospital who presented the anomalous picture of a cranium larger than normal but a defective mentality. As almost the only thing which can cause the head to enlarge, and at the same time reduce the mental capacity, is hydrocephalus, Dandy set about obtaining a ventriculogram. He withdrew a quantity of cerebro-spinal fluid by a puncture of the posterior horn of the lateral ventricle, and injected an equal amount of air. Radiography demonstrated an enormously distended ventricle, the picture being one pathognomonic of hydrocephalus. Mental impairment is not universal in achondroplasia, at least in its earlier stages. It is difficult to understand precisely why hydrocephalus should develop in this affection. Dandy inclines to the view that the crowding of the base of the brain causes narrowing of the arachnoid cisternae, or that there may be a kinking of the iter. He admits that this is pure hypothesis, and we must await further investigations.

"AESTHESIOSCOPIA ABDOMINALIS."

A SCANDINAVIAN worker, Dr. T. B. Wernöe, has described a method for detecting areas of hyperaesthesia in the skin of the abdominal wall.¹ The method depends on the observation that when warm skin is cooled it becomes paler owing to reflex vaso-constriction; in the presence of hyperaesthesia this reflex is exaggerated, and an area of hyperaesthesia exposed to the air becomes paler than the neighbouring parts. The difference is not very marked in bright illumination; but if the abdomen is turned away from the light and a little time is allowed for the reaction to develop and for the observer's eye to become accustomed to the dim illumination, the difference between hyperaesthetic and normal areas will be sharply defined. Compared with pinprick methods of testing for hyperaesthesia, this method has, it is said, the advantages of greater rapidity, accuracy, and objectivity. The author reproduces figures showing the shape, size, and distribution of the areas of hyperaesthesia mapped out by his method, and he regards it as applicable to intrathoracic conditions, such as pericarditis, as well as to abdominal and pelvic conditions. Hairly and pigmented skin does not show the reaction well, nor does skin which is much exposed to the air. The author records a fatal case of traumatic ileo-caecal invagination in which the site of the intestinal obstruction was clearly indicated by aesthesiopia.

INDUSTRIAL WELFARE AND RESEARCH.

A YEAR or two ago a number of business men, who were faced continually with the effects of growing unrest and discontent in industry, came to the conclusion that the prevailing spirit was due largely to the lack of the old personal touch between employer and worker. It seemed to them that the industrial welfare movement provided both a valuable means whereby this link of friendship could be restored and a method of removing many of the causes of the trouble by showing to employer and worker alike their many common interests. In order to extend this movement the Industrial Welfare Society was formed, and its policy has been warmly approved by many hundreds of firms in which a better feeling between the workers and employers has been created. The growth of this society has been continuous, but in order to obtain the larger financial support necessary an appeal had to be made to the wider public. A conference on industrial welfare was therefore held at the Mansion House on March 2nd, and speeches were made by the Duke of York, Sir Charles Wakefield, and others. Before, however, there could be recaptured for modern industrial concerns the spirit of co-operation and fellowship that existed in the days of the old craft guilds between master and apprentice, there must be properly conducted research into the practical application of science to the human

¹ W. E. Dandy, *Proc. Roy. Soc. Med.*, 1920, 13, 100.
² *Nature and its Causes*, 1918, 10, 100.

conditions of modern industry. For this purpose has been founded a National Institute of Industrial Psychology, and the first meeting of its Council was held on March 3rd. The chairman, Mr. H. J. Welch, referred to the three branches of the proposed work of the institute—vocational guidance and selection, fatigue research, and movement study—the purpose of all three being the elimination of human waste and friction. The application of scientific knowledge to the human factor in work should not only increase production at low cost, but also add to the happiness and contentment of mankind. Mr. Welch explained that the main object of the new institute was to combine scientific research with practical work in commerce and industry; it was not established for profit, and all the fees received would be used to further these aims. Dr. C. S. Myers, F.R.S., Director of the Psychological Laboratory, Cambridge, who has been one of the moving spirits in the foundation of the institute, emphasized the necessity for careful research. An executive committee of the institute was thereafter formed, and also a scientific committee, including representative psychologists and physiologists. The office of the institute is at 329, High Holborn, W.C.

YELLOW FEVER IN NORTHERN PERU.

THE series of investigations into the etiology of yellow fever undertaken by Noguchi in South America, which has resulted in the description of *Leptospira icteroides* as the causal agent, has now been extended to Northern Peru by Noguchi and Kligler.¹ The *Leptospira icteroides* was first isolated by Noguchi from cases of yellow fever at Guayaquil in Ecuador, and subsequently from a case at Merida in Mexico; these strains were shown to be morphologically and serologically identical. Peru, which has suffered many visitations by yellow fever, was again invaded in June, 1919, and this outbreak had not disappeared entirely when Noguchi and Kligler arrived in March, 1920. The mortality was estimated at about 10 per cent., which is much lower than the 50 per cent. mortality in Guayaquil and Merida. Fourteen typical cases of yellow fever were studied in Northern Peru, nine in March, 1920, at Payta, where the laboratory facilities were very imperfect, and five in April and May at Morropon and Piura. A typical leptospira infection, together with the demonstration of the organism in experimentally infected guinea-pigs, was obtained in four, and in the majority of instances indications, such as fever, haemorrhagic areas in the lungs, and occasionally a suggestion of jaundice in the inoculated guinea-pigs, were observed; in a few cases only were the results entirely negative. The leptospira isolated from the Morropon cases of yellow fever was morphologically and culturally identical with the Guayaquil and Merida strains of *Leptospira icteroides*, and was shown by immunity tests to be indistinguishable from the Guayaquil strain. Study of the immunology of the Peruvian strains proved that the serum of patients convalescent from yellow fever at Payta, Morropon, and Piura gave a positive Pfeiffer reaction with leptospira strains isolated in Guayaquil and Merida, and in the majority of instances protected guinea-pigs from these strains. The virulence of the Morropon strains was approximately the same as that of those from Guayaquil and Merida. Suitable quantities of the anti-icteroid immune serum prepared with the Guayaquil strains administered to guinea-pigs inoculated with 2,000 to 20,000 minimal lethal doses of infective material prevented infection or death, according as the serum was given during the incubation period or after fever had appeared. Guinea-pigs from Payta were much more resistant to infection with leptospira than were guinea-pigs recently imported from New York. It was found that rabbit serum that had undergone long journeys in a tropical climate deteriorated as a culture medium for

Leptospira icteroides, and that failure to obtain a growth in such serum occurred, whereas a growth was obtained with fresh rabbit serum; but the Peruvian strains had a tendency to degenerate early in culture.

ARTIFICIAL LIMBS.

DR. GABRIEL BIDOT, who is known as an orthopaedic surgeon and an advocate of a system of artificial muscles for the instrumental treatment of paralysed and weakened limbs, has contributed a short paper to the Medical Society of the Paris Hospitals on the improvement of artificial limbs.¹ He complains that the limbs at present supplied are defective owing to their weight, the practical absence of support and of a proper seat for the tuberosity of the ischium. The result of the last two defects is that the stump is forced into the socket in an attempt to get support. Dr. Bidot does not say what the weight of any French limb is or should be, nor does he mention any average weight for any type of limb. It is therefore impossible to make comparisons between the limbs he criticizes and those of the Ministry of Pensions in this country. From such evidence as is available we are inclined to the opinion that our own official limbs are superior to the French, and probably to those of all the other belligerent nations. Although Dr. Bidot adversely criticizes willow-wood and raw hide sockets, he does not recommend any substitute, but he advocates the use of artificial muscles for the control of prostheses in a manner similar to that which he has recommended in his pamphlet on instrumental orthopaedics.

THE Senate of the University of London, on March 16th, adopted a resolution to continue the physiological laboratory at South Kensington until the end of the current triennium—that is, until the end of 1923.

A DINNER of congratulation to Professor Sherrington on his election to the presidency of the Royal Society was given by the Physiological Society on March 11th at the Café Royal, London. Professor Sir E. Sharpey-Schafer, who presided, proposed the toast of the guest, and his speech and Professor Sherrington's reply were the only speeches.

PRESENTATION TO DR. J. A. MACDONALD.

THE following further subscriptions have been received from February 6th, to 28th, 1921, in response to the appeal published in the JOURNAL of July 24th, 1920 (p. 129), towards a presentation to Dr. J. A. Macdonald on the occasion of his retirement from the office of Chairman of Council of the British Medical Association which he had held for ten years. Subscriptions of any amount not exceeding five guineas should be made payable to "The Macdonald Presentation," and sent to the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2.

Medical Notes in Parliament.

Criminal Law Amendment: The Bishop of London's Bill.

IN the House of Lords, on March 9th, the Bishop of London moved the second reading of a Criminal Law Amendment Bill based on that which he introduced last year. The earlier measure, a bill brought forward by Earl Sandhurst for the Government, and another by Earl Beauchamp, were referred to a Joint Committee of Lords and Commons under the chairmanship of Lord Muir Mackenzie. The report of this Committee, which contained recommendations to the Government, was published during the recess. The Bishop of London's new bill contains six clauses. Clause 1 lays down that it shall be no defence to a charge of indecent assault on a child or young person under the age of 16 that he or she consented. Clause 2 proposes to raise the age, in the sections of the criminal law relating to carnal knowledge of a girl from 16 to 17, and to repeal the subsection which makes "reasonable cause to believe that a girl was 17 years of age" a defence. It further proposes that the period within which complaint may be made shall be extended from six months to twelve. Clause 4 would heavily increase the fines and terms of imprisonment for brothel keepers. To relieve the bill of controversial matters the bishop left out of it any proposals to deal with the communication of venereal disease, the compulsory detention of young girls in homes, the prevention of prostitution in flats, and the former clause for the protection of boys. He explained that the reason why he now asked for the age of consent to be raised only from 16 to 17, and not to 18, was that Lord Muir Mackenzie's committee did not favour raising the age. Moreover, he thought that raising the age one year, with repeal of the subsection allowing reasonable belief as a defence, would mark a great advance. The bishop quoted from a report as to the conditions of London not yet published by the County Council. This showed that in the clinics of London (and only about one tenth of the cases went to these clinics) there were 27,364 new cases in 1919, and 293,066 attendances. In the London Hospital clinic the numbers had increased from 658 new patients in 1918 to 1,452 new cases in 1920. These medical authorities reported in their careful summary that a large percentage of the patients was quite young—from 16 to 20 years of age. They said that seduction and desertion operated powerfully as a cause of prostitution. Referring to the proposals put forward by the Society for the Prevention of Venereal Disease for the distribution of packets and allowing chemists to sell preventives, etc., the bishop said he agreed with the late Lord Downham when he said that if this sort of thing really came to England it would be the beginning of the end. Coming to the work of the National Council for Combating Venereal Diseases, the bishop thought that its progress must necessarily be very partial and slow. In answer to the argument for license! attention Flexner's work on *Prostitution* proved that in every capital in Europe increased in almost exact proportion system was introduced.

Lord Onslow (for the Government) stated that, in view of the differences of opinion in the Joint Committee on the Government's bill of last year, it would not be reintroduced. The bill now presented by the Bishop of London omitted the most highly controversial matters, and the Government regarded it sympathetically, and would, if it progressed without material change, consider whether time could be found for it in another place. As for the age of consent, the Government bill proposed to leave it at 16; but the Home Secretary considered that the balance of opinion, in view of the further arguments, was for raising the age to 17.

Lord Phillimore, after reminding the House that he had sixteen years' experience as a judge of assize, gave his reasons for holding that if the subsection as to reasonable cause to believe were taken away the age should not be raised to 17, but ought to be reduced to 15. If the subsection were retained, the age might, he thought, be raised to 17. The Earl of Malmesbury, speaking as a member of the Joint Committee, held that the age should, with the removal of the subsection, be kept at 16. Lord Coleridge, recalling, like Lord Phillimore, assize experience, thought that if the raising of the age to 17 were accompanied by removal of the reasonable belief ground of defence, Parliament would be going beyond public opinion. Viscount Cave said he would rather have the clean cut—retain the age of 16, and abolish the particular defence, than raise the age and leave the defence standing. He said this with twenty years' experience as chairman of quarter sessions, and from what he had learned from London magistrates when he was at the Home Office. Lord Gorrell supported the bill as it stood, emphasizing the amount of support it had behind it from organizations.

Lord Dawson of Penn concurred with other peers as to the gravity of the evils, but feared that in some respects the bill would not succeed in removing the evils they greatly desired to remove. He did not say that the bill was not a good one; but as to Clause 1—consent no defence in indecent assault cases—at instinct which was based on nature and the sexual instinct which was unnatural and perverted. He took it that this clause was mainly directed against the older offenders—men on too heavily; but the clause seemed to him to include the possibility of bringing into its meshes the young, and possibly

the boy of 18 accused of an offence against a girl of 15 or 16. It seemed to him that such offences were on an entirely different footing. That was the natural instinct which overflowed at an age when restraint was deficient. Such young people did not require the dock. They rather required education, uplifting and moral suasion. He suggested that some proviso should put them on a different footing from the older offenders. On the question of the age of consent for carnal knowledge from 16 to 17, Lord Dawson assumed that when the Legislature raised it to 16, the view was taken that the young person of 16 was too immature to be what he might call "a conscious sexual instigating agent." But after 16, the changes taking place in a girl were often very rapid, very capricious, and very marked. It was quite easy to select five or six girls at the age of 17 who could represent by appearance any age from 15 to 21. It was the fact, therefore, that after 16 the girl was apt to develop very quickly and with that development became a conscious sexual agent. That was where his difficulty lay in raising the age. He was anxious to give all the protection that could be granted; but the moment the girl became a conscious and often an intentional instigating agent it seemed to him extremely difficult to throw the whole blame for sexual misdoing upon the man. The girl became jointly to blame with the man with whom she offended. It was a curious fact that the large body of public opinion which was constantly maintaining that there should be an equal standard of responsibility for the two sexes—a view with which he had considerable sympathy—should now be willing to protect the girl at the expense of the man. Example after example could be quoted where the girl could be the prime offender, and vice versa. It did not seem right to him to throw the whole onus on the man. He wished it to be clearly understood, however, that he was not concerned with the older man. The older man of 25 had developed a certain amount of stability and was quite capable of forming just opinions. There was another point of view which made one hesitate about placing responsibility for sexual intercourse exclusively on the male. Certain physical realities of life seemed to have been almost entirely ignored by many earnest social reformers. Coming down to consider the elemental things of life, it would be agreed, as to the instincts that moved men and women in sex matters, that the first outstanding instinct of the male was pursuit. It might be checked in civilized society by moral and religious ideas; but it was elemental. The instinct of the female was resistance and reserve, followed, it was true, by surrender; but, broadly speaking, she had the reserve, the resistance. That physical instinct was the basis of woman's modesty. Of all the forces that existed anywhere for sexual morality the most potent individual force was woman's modesty. The second point he wished to bring out, viewing the matter from the point of view of physical realities, was that the desire of the woman was much more conditional than it was with the man. The average woman had to love before she had passion, or, at any rate, she had slowly to develop a strong liking for an individual before that passion was aroused. She had none of the promiscuous qualities of the male, and unconsciously or consciously her sexual instinct was associated with the conception of maternity. She was therefore much more protected by Nature than the male. The ordinary girl of between 16 and 17, if reasonably brought up, had a much greater natural defence than the male. That raised a doubt in his mind as to throwing the whole responsibility on the male. Either the age must be left as it was or both male and female must be made responsible before the law for illicit sexual intercourse. With regard to brothels, he entirely agreed that the heaviest possible penalties should be put on the proprietors of places where proprietors farmed the earnings of women who resorted to them or where such women lived or resorted. But he had an apprehension whether, if legislation were too repressive, so that small hotels conducted in an orderly manner were brought within the law, the base of promiscuous intercourse might not thereby be further widened—driven into places, and even into the homes. For that reason caution was an attitude of no action. Many provisions in the bill could be supported with confidence. But he did not believe that the problem of promiscuous intercourse was going to be met by legislation. It was going to be met by social reform and betterment; by encouraging the idea of garden grounds for the people, and the better remedies, it seemed to him, the return to the larger family, and the frank recognition that if people were going to marry they must have control over the output of their offspring.

Lord Muir Mackenzie said that the bill—as far as it went—coincided with the recommendations of the Joint Committee, except in raising the age of consent to 17. The Committee agreed on the age of 16 and to get rid of the defence of "reasonable cause."

The bill was read a second time. The measure was taken in Committee in the House of Lords on March 15th. The Bishop of London announced that, having regard to the discussion on the second reading of the measure, he was willing to accept an amendment, standing in the name of Lord Muir Mackenzie, which would retain the age of 16, but provide that reasonable cause to believe that a girl was over 16 years of age should not constitute a defence. He believed that by getting rid of that ground of defence there would be a great gain of protection for young girls; and, if the

measure passed through their Chamber as an agreed bill, there would be a greater possibility of its being accepted in another place. Lord Muir Mackenzie afterwards moved to substitute for Clause 2:

"Reasonable cause to believe that a girl was of or above the age of 16 years shall not be a defence to a charge under sections 5 and 6 of the Criminal Law Amendment Act."

This was accepted. The Lord Chancellor moved a new clause repealing the present law under which proceedings under the Incest Act are held in camera. This also was agreed to.

The Increase of Cancer.—In reply to Mr. Gilbert, on March 9th, Dr. Addison said that an extensive research into the causes of cancer had for some time past been undertaken by the Imperial Cancer Research Fund, and the Medical Research Council was facilitating research into the possibilities of radiotherapy and had been the means of providing a substantial quantity of active radium salts for the purpose. Cancer research funds were relatively well supported from voluntary sources, and he did not think that the issues were sufficiently clear for him to recommend grants in aid of the cost of the treatment of this disease at the present time.

Malaria Cases in Great Britain.—Captain Elliot asked, on March 9th, whether, in consequence of the number of men in this country who still suffer from malaria contracted abroad during the war and of the abundance of mosquitos present in many parts of England, malaria was now occurring in the civil population. Dr. Addison replied that the action taken was fully described in two separately issued reports on malaria contracted in England relating to 1917 and 1918 respectively, and in the annual report of the chief medical officer for 1919-20. The policy of prevention was based primarily on securing the early detection of all cases and carriers of malaria and arranging that the cases were thoroughly treated with quinine, thus removing, or greatly lessening the risk of infection if they were bitten by mosquitos which could spread the infection. Efforts were made at the same time to protect all such cases and carriers against mosquito bites as far as possible. Special supervision for these purposes had been arranged in the Isle of Sheppey, where most of the infection arising in England had occurred. The measures taken had greatly lessened the risk of spread. The total number of locally contracted cases reported among the civil population in England was only 32 in 1920, as compared with 93 in the previous year.

Lunacy Act Terms.—Dr. Addison stated, on March 10th, that he was in sympathy with the spirit of the resolution passed by the Committee of Visitors to the Isle of Ely and Borough of Cambridge Mental Hospital, that the terms "pauper lunatic" and "pauper lunatic asylum" should be discontinued, and that the terms "patient" and "mental hospital" should be substituted. The change, however, would require considerable amendment of the Lunacy Act, and he feared that words substituted would tend to acquire the same associations.

The Dental Bill.—Dr. Addison stated, on March 10th, that he hoped to confer shortly with the various representative organizations concerned with a view to the introduction of the Dental Bill as an agreed measure, but he was not at present in a position to name any date for the introduction.

Tuberculosis Treatment.—Dr. Addison assured Sir Arthur Holbrook, on March 9th, that the question of adequate and permanent representation for the members of the Insurance Committees upon the new Committees to be appointed on the transfer of tuberculosis treatment to County and Borough Councils was being borne in mind by him in regard to coming legislation.

Ministry of Pensions Expenditure: The Medical Services.—In answer to Lieut. Commander Kenworthy, on March 7th, Mr. Macpherson replied that the expected total annual cost of administration of the Ministry of Pensions for the current year approximated to £6,500,000; of that amount £3,000,000 related to general administration, £2,300,000 to medical services, and £1,240,000 to local war pensions committees. The number of persons (excluding widows, children, and dependants) in receipt of pensions on August 1st, 1920, was 1,117,000, and on February 1st, 1921, it was 1,060,000, and the respective annual costs thereof £61,598,000 and £60,484,000. The annual expenditure incurred in respect of medical boards was £1,712,000, the cost in salaries and fees to medical officers being £994,000. There were 564 whole-time medical officers employed on August 1st, 1920 (215 being engaged in institutions), and 592 employed on February 1st, 1921, of whom 257 were engaged in institutions. The number of disabled men who were in receipt of pensions on August 1st, 1920, and had now ceased to draw pensions by reason of death, being settled by gratuity or a final weekly allowance in lieu of pensions, and of their disability having become less than 20 per cent., was 103,000. The number of 20 per cent. and 30 per cent. pensions in payment at February 1st, 1921, was 390,000 and 245,000 respectively. Lieut. Commander Kenworthy also inquired what parliamentary authority there was for the constitution of medical boards composed of three medical men. Mr. Macpherson, in reply, referred to the agitation which led to the formation of such boards.

Pensions Appeal Statistics.—Mr. Macpherson, at the instance of Mr. Cape, stated, on March 8th, that the number of appeals heard by the pensions appeal tribunals between February 28th, 1920, and February 28th, 1921, was 14,487; of this number 4,334 were allowed and 10,103 were rejected.

Health of Soldiers at Cologne.—Lieut.-Colonel Buckler asked the Secretary for War, on March 8th, whether his attention had been called to the grave allegations concerning the Army of the Rhine made by the Rev. W. Talbot Hindley, a chaplain of the Territorial Force; and, in particular, whether there was anything to justify the statements that the conditions of life in Cologne made a death-trap for our soldiers, that 95 per cent. of one unit had been through hospital, and that there was a cemetery largely filled with suicides and victims of venereal disease. Sir L. Worthington-Evans said that the Army Council was in communication with the reverend gentleman concerning these. There was no justification whatever for the statements attributed to him. During the period from January 1st, 1920, to January 31st, 1921, the monthly average of admissions for venereal disease was 1.4 per cent. of the total strength; there were 85 deaths from all causes, but none from venereal disease; 5 were due to wounds self-inflicted.

Dangerous Drugs in India.—Mr. Montagu informed Mr. Gilbert, on March 9th, that in India the regulation of the traffic in and use of dangerous drugs is controlled by a variety of local and Imperial Acts. It is believed that the law and practice in India in respect of such drugs are entirely in accord with the provisions of the Hague Convention. Some time ago, however, the Government of India was requested to look into the matter and to effect such amendments, if any, as might be required.

Insurance Committees and Medical Record Cards.—Replying to Mr. Bartley Dennis, on March 9th, Dr. Addison said that he had received representations as to the new medical record cards from only four Insurance Committees. In three cases the representations were on matters of detail, and in the fourth the Committee had resolved that the keeping of the records was desirable for securing a proper medical service. The Chairman of the National Association of Insurance Committees had written that the Executive Committee of that body held that the keeping of the records was unquestionably in the interests of the insured persons.

Termination of Sanatorium Benefit.—Dr. Addison, in answer to Mr. Wignall on March 8th, said that the date fixed for the termination of sanatorium benefit in England and Wales was April 30th next, and he was hoping to introduce shortly a bill dealing with the arrangements to be made for the treatment of tuberculosis after that date.

Wellhouse Hospital, Barnet.—In answer to Lieut.-Colonel Fremantle, on March 9th, Dr. Addison stated that a loan of £40,000 was sanctioned for the erection of Wellhouse Infirmary, Barnet, and £38,505 were raised by the guardians. The infirmary was opened only recently, and no figures of the running costs, or of the amounts recovered from persons relieved in the infirmary, had yet been returned. The clerk to the guardians reported that the staff numbered 36, and there were also two consultants.

Whole-time Medical Officer for Bromley.—Asked by Lieut.-Colonel James, on March 2nd, as to the proposed appointment of a whole-time instead of a part-time medical officer for Bromley, Dr. Addison said that the whole-time public health staff employed by the Bromley Borough Council consisted of two health visitors acting under the general supervision of the Medical Officer of Health. There were in addition certain officers employed on the school medical service. The appointment of a medical officer of health rested with the Borough Council, and the proposal to employ a whole-time medical officer of health came from them. In addition to performing the duties of medical officer of health, whoever was appointed would act as supervising school medical officer and be in charge of the maternity and child welfare of the borough. He was advised that the proposed arrangement would be economically useful, and did not see his way to withhold general approval of it.

Clinical Thermometers.—Mr. Kiley asked, on March 7th, whether a manufacturer of clinical thermometers was liable to be sent to prison in selling his products accompanied by a certificate that they had been tested unless the goods were sent to a Government department to be again tested. Sir P. Lloyd-Greame said that a seller had to comply with the Order in Council made during the war under the Defence of the Realm Act.

Glamorganshire County Asylums.—Dr. Addison, in reply to Mr. Stanton, on March 3rd, said he was advised by the Board of Control that an expression used by Mr. A. B. Marriott at the Merthyr Tydvil Board of Guardians on the previous Saturday, namely, that the patients at the Glamorganshire asylums were herded together, was not justified by the facts. The reports on the institutions which had been received did, however, indicate certain defects, and he was having the matter further investigated.

Answers in Brief.

The agreement for the supply by the Government of India of opium to the Government of Hong Kong has been renewed for a further period of five years, with certain modifications. Under the new agreement, which has effect from January 1st, Hong Kong will be supplied with ten chests of opium per month at a fixed price. No obligation rests on the Government of Hong Kong to take any prescribed minimum quantity.

Grants amounting to £1,000,000 will be made during the current financial year to local authorities on maternity and in the £ on the total sums voted by Parliament for the supply services of the country.

South Australia.

[FROM OUR SPECIAL CORRESPONDENT.]

MEDICAL LEGISLATION.

THE session of Parliament which has just closed has seen the enactment of several laws affecting, more or less, the medical profession. First and foremost the Venereal Diseases Act brings the State into line with the sister States of the Commonwealth. It provides for the treatment of patients either by a private practitioner or in a public institution until they have received a certificate of "cure" or of "freedom from venereal disease"; it prohibits any but medical practitioners treating such cases; it requires the practitioner to notify the Inspector-General of Hospitals of the case, without divulging the name or address unless the patient ceases to attend the doctor or institution, in which case his name and address is to be furnished. It provides for the education, by means of suitable literature, of the person infected, for the warning of the other party if marriage be contemplated, and it penalizes the individual who knowingly communicates any such diseases either in matrimonial or illicit intercourse. Another sweeping prohibition is that which forbids an infected person to work in any shop, factory, hotel or steamer, etc., in any capacity which involves the handling of food. There is a clause also which prohibits the obnoxious advertisements common even in respectable lay newspapers. Treatment is to be compulsory, and therefore, as a natural corollary, free treatment is to be provided; female sufferers may demand examination by a medical woman, if there be such a one, willing to act, and resident within twenty miles. The Act positively bristles with penalties, chiefly directed against medical practitioners, and ranging from a modest fine of £5 up to five years' imprisonment, with or without a mulct of £500. In considering the bill legislators seem to have been governed by the optimistic opinion of certain specialists, who asserted that these diseases might be exterminated; so they might, but we heard the same thing about tuberculosis five-and-twenty years ago. So far as the Act insists upon adequate treatment it is good, but the general opinion is that it will be found unworkable, and that it will be impossible to maintain the idea of secrecy; great and unnecessary hardships will, it is thought, be inflicted. What employer would take back the grocer's assistant or the restaurant waitress who has suddenly to vacate a position? It is asked whether the tests as to the existence of these diseases, and still more as to their cure, are absolutely trustworthy: whether, indeed, the correct principles of treatment of either syphilis or gonorrhoea are yet standardized. The almost universal prevalence of syphilis in some form was roundly asserted, and legislators were frightened by the statistics, and, withal, so innocent that one of them even thought that a doctor could determine freedom from venereal disease "in young girls" by a cursory examination consisting of lifting up an eyelid. Labour members especially were afraid that doctors would be bribed to give false certificates unless the fines were heavy.

THE OPTICIANS ACT.

The opticians have now obtained their wish. There is to be a "Board of Optical Registration"; it will consist of three competent opticians and two registered medical practitioners, and a majority of its members will be nominees of the Government. As, however, there is a suspicion that the Board may be boycotted by the doctors, provision is made for the whole Board to be composed of opticians. Paid examiners are to be appointed to examine budding opticians who aspire to practise optometry and to be registered as opticians. They are not to call themselves oculists, nor to use mydriatics, nor to prescribe for eye diseases. Another duty of the Board is to license spectacle sellers, but such vendors shall not aspire to practise optometry. Woe to the hawk who "peddles, barters," etc., spectacles. Master Moses Primrose will run no risk in future of being taken in by the itinerant vendor. The eye specialists opposed this Act on the grounds that the opticians who prescribe spectacles often overlook diseases of the fundus. Doubtless this is sometimes true, but the evil is probably exaggerated, and with the limitations prescribed by the Act it is difficult to see what

greater harm will be done by registering them: doubtless also a tendency will grow to create a close guild of opticians.

Nurses' REGISTRATION ACT.

The examination and registration of South Australian nurses has hitherto been conducted chiefly by the Australian Trained Nurses' Association, which has its headquarters in Sydney, but probably in future this function will be taken over by the newly-appointed Nurses' Board of South Australia. There are to be three classes: ordinary nurses, mental nurses, and midwives. With respect to the latter the Board has power, in order to prevent the spread of diseases, to inhibit a nurse, registered or unregistered, from practising as a midwife, and after the expiration of a year no woman will be allowed to act as a midwife who is unregistered, emergencies excepted, such as a confinement occurring more than five miles from the nearest doctor or midwife. The other provisions of the Act do not call for comment.

Scotland.

WINTER CLINICAL MEETING OF THE EDINBURGH BRANCH.

THE winter clinical meeting of the Edinburgh and some other Scottish Branches of the British Medical Association was held in the Royal Infirmary, Edinburgh, on March 4th, and was in every respect most successful. The museum of pathological and other specimens, which was open all day in the pathological department, was visited by a large number of members. From 10 a.m. until 3.15 p.m. a number of demonstrations were given in the wards and special departments on, for instance, "Modern methods of treatment of syphilis and gonorrhoea," by Mr. D. Lees; "The colloid gold test for cerebro-spinal fluid in general paralysis of the insane and other disorders," by Miss Wilson; "The therapeutic uses of radium," by Dr. Dawson Turner; "Cases illustrating a new method of treatment by tuberculin," by Sir Robert Philip, and others by Dr. J. V. Paterson and Dr. A. H. H. Sinclair, Dr. Hope Fowler and Dr. A. McKendrick, Dr. Chalmers Watson and Dr. Lipschitz, and Dr. Norman Walker. At the clinical demonstration in the evening the large surgical theatre of the infirmary was almost filled. Dr. J. J. Graham Brown, president of the Branch, was in the chair, and a large number of interesting cases were shown by members of the medical and surgical staffs of the Infirmary. At 5 p.m. an address was given by Dr. J. S. Haldane, F.R.S., of Oxford, on "Some recent advances in the physiology of respiration, circulation, and renal excretion," which was listened to with very evident appreciation; the address is published in this issue of the JOURNAL (p. 409). In the evening a dinner was held in the Caledonian Station Hotel, which proved to be a most enjoyable function, although the number present was rather less than last year. Among the guests, besides the Chairman of the Scottish Committee and the Scottish Secretary of the Association, were Sir Robert Philip, President of the Royal College of Physicians of Edinburgh, Dr. George Mackay, President of the Royal College of Surgeons of Edinburgh, one of the Presidents of the Royal Medical Society, and one representative resident from the Royal Infirmary. The honorary secretary of the Edinburgh Branch, Dr. John Stevens, must be congratulated on the continued success of the annual winter clinical meeting.

Ireland.

THE DUBLIN ASSOCIATED HOSPITALS.

THE accounts of the fête held at Ballsbridge last October were presented to a council meeting of the Dublin Associated Hospitals Fund at the Royal College of Physicians on March 10th. The gross receipts amounted to £19,684; after paying expenses, the net balance was £15,655. The Lord Chancellor (Sir James Campbell), who presided, said that the result might be regarded as satisfactory, although some hospitals might have done better. Sir Patrick Dun's Hospital headed the list with £2,305, the Meath Hospital came next with £1,986, Stevens's Hospital third with

£1,632, and the Royal City of Dublin Hospital fourth with £1,527. Changes had been made in the administration of the hospitals in Dublin which he hoped would relieve the public to a large extent of the perpetual appeals for assistance. Arrangements had been made for a better system for paying patients and for obtaining contributions from the poorest; in the future the county councils would bear a fair share of the expenses incurred by the hospitals in treating the inhabitants of their districts. Most of the county councils had admitted the claims of the hospitals in a generous spirit. Sir Henry McLaughlin, the honorary organizer of the fête, said that the general position of the Fund was unsatisfactory. The total amount of the collection over and above the balance from the fête was £19,200; of this about £10,000 had been raised in country districts; about £9,000 had been subscribed by Dublin citizens. Plans which they had for a winter campaign had to be given up owing to the curfew orders. Professor James Craig, President of the Royal College of Physicians, proposed the following resolution, which was carried: "That the effort being made to remove the debts from the Dublin hospitals is worthy of the consideration of the business and commercial interests of the city." He said that, if the hospitals were not supported, either the hospitals must close or they must come under State or municipal control, either jointly or separately. If the latter alternative came, it followed that the hospitals would probably be under different management. There would be democratic control, and democratic control, he believed, would in this case be a mistake. He hoped the business and commercial men would see to it that the Dublin hospitals did not come under either State or municipal control.

Correspondence.

X-RAY RADIATION AND CANCER.

SIR.—The letters of Dr. Hernaman-Johnson and Dr. Mitchell require an answer, as they preach a pernicious doctrine. They seek to substitute a new and untried method, claiming to be based on certain animal experiments, for a treatment that has been worked at for years, the limitations of which are known, a treatment which has given steadily improving results as the doses and the penetration of the rays have been increased. The Erlangen method is a development on lines along which I have been striving to advance for many years, but have been prevented by inadequate apparatus. Whether one treatment will ever be sufficient to destroy a carcinoma is doubtful. The Erlangen school use two in carcinoma of the cervix, only they say that one is for the cervix and the other for the parametrium. I have not yet had an opportunity of investigating this treatment on the spot, but the theory is sound, though it is almost certain that the results will not be as good as is claimed. The method is bound to be a dangerous one, as great accuracy is necessary in the directing of the beams of x rays.

I for one will assert that x -ray treatment of carcinoma of bone—though one rarely gets a chance of treating this condition—has immeasurably improved in the last few years, together with the radiation treatment of all other deep-seated malignant growths.

Why should the experiments be ignored which show that radiation of a malignant growth will, if sufficient, prevent its implantation into another animal, and, if enough, but not too much, radiation has been given, will immunize the animal in which it is implanted? The experiments mentioned in the paper by Professor Russ and his colleagues were irradiation of the whole animal at a considerable distance from the tube, so far that to get a similar result on the much bigger human being the x -ray source would have to be at the other end of a long room. It is even possible that our radiations of a comparatively small section of the body, may have a similar effect to these doses on the whole body of the small and easily penetrated rat. The experimenters with small doses have never claimed more than that in a larger proportion of the irradiated animals than in the controls the growth did not "take." In a quite considerable percentage the growth did "take."

I see many cases where insufficient irradiation has failed or has even apparently stimulated a growth and yet

which, when large doses are employed, show marked and rapid improvement.

The treatment has its limitations; not all types of growth are suitable. At the same time it is not all growths which are stimulated by insufficient irradiation, but I have seen a few cases in which this has apparently occurred—only a few, as I take care to give large enough doses.

As to combining radiation treatment with surgery, the proper method is first of all to give a thorough irradiation to prevent implantation of cancer cells, taking care not to injure the skin; next to excise the growth as thoroughly as if no radiation had been used, and then to do prophylactic treatment.

I am convinced that the future in radiation treatment of malignant disease lies in more penetration and bigger doses.—I am, etc.,

London, W., March 14th.

N. S. FINZI.

SIR.—Dr. William Mitchell asks whether the statement so often made "that weak doses (of x rays) stimulate malignant growth" is one of the "myths" that are constantly copied from one writer by another or whether there is any evidence, experimental or otherwise, to prove it.

I think I may be in part responsible for the statement, for in my Hunterian Lecture on x -ray cancer and the conditions that precede its onset, delivered in 1909, I brought forward the results of experiments on rats and rabbits that appeared to afford unmistakable evidence of "stimulation" of small doses of x rays upon normal

It obviously would be a matter of extreme difficulty to furnish experimental evidence of any value in regard to a similar effect upon malignant epithelium owing to the impossibility of setting up a fair standard of control. But it is noteworthy that the epitheliomas of the skin of x -ray operators, which constitute the only known examples of the experimental production of cancer in man, would appear in the majority of cases to have been occasioned by oft-repeated casual doses, resulting from lack of protection and not by a massive and at once injurious dose.

It is also, I think, worth remembering that the effective dosage delivered by any stream of x rays must at some point in its passage through the tissues become a small one, dependent, of course, upon the various technical details concerned in its production, and upon the degree of absorption by the tissues through which the stream is passing.—I am, etc.,

London, W., March 14th.

Cecil Rowntree.

SIR.—In the discussion of this important matter, it is necessary to avoid misconception. Dr. William Mitchell, in your issue of March 12th, makes the following statement: "I have seen it too often to have any doubt on the subject that operation for mammary carcinoma, of even the most favourable type, and done in the most thorough manner by the most capable surgeons, is followed in a large percentage of cases [the italics are mine] by rapid dissemination, which I am sure could have been averted by pre-operative treatment" (that is, x -ray radiation). Dr. Mitchell's experience must have been singularly unfortunate, and I venture to think unique. Every surgeon has probably met with early cases of cancer which appeared very favourable for radical operation; yet the operation proved a disappointment, and rapid dissemination supervened. But, apart from Dr. Mitchell's unfortunate experience, to imagine that this occurs in a large percentage of cases would surely be a gross misconception of fact. It is surely and fortunately quite a rare event. Whether in these cases a pre-operative course of x -ray radiation would have prevented its occurrence is difficult if not impossible to prove.

My objection to the pre-operative x -ray radiation of cancer is that it keeps the patient dallying with his disease, encouraging him in his natural desire to avoid operation by a seeming or real improvement in his condition, losing time which may mean him losing his life. When the certainty of cancer exists the sooner it is removed the better, and I should require much more convincing proof than the *ipse dixit* of the radiologist that he was sure that rapid dissemination could be prevented by a

course of pre-operative x-ray radiation before advising a patient to postpone operation for operable cancer a single day. On the other hand, I have for many years past advised my patients to undergo a course of post-operative x-ray radiation. There are these clinical facts about cancer: In some cases where the local origin is quite insignificant there is a great tendency to rapid and wide dissemination, and that quite apart from any operative procedure whatever. In other cases where the local origin is extensive the disease seems to expend itself locally, and the tendency to dissemination is much less. That is, so far as I know, one of the mysteries of this mysterious disease. That is why it is always worth while to remove cancer, however extensive, provided there is a reasonable chance of getting the palpable disease away. The most apparently hopeless case of carcinoma of the breast, from the point of view of prognosis, that I have ever operated upon—a young woman with a large and rapidly growing medullary carcinoma filling the breast, and secondary glands as large as walnuts in both the axillary and supraclavicular regions, advised, and apparently justifiably advised, against operation by a very eminent London surgeon—sent to me by Dr. H. W. Jeans of Portsmouth, is alive and well now, ten years after operation. In this case, wishing to give her every loophole possible in an apparently forlorn hope, I removed both her ovaries as well. Whether this had anything to do with the result of the operation I do not know. But the next case in which I tried it had a very rapid recurrence. The vagaries and uncertainties of this mysterious disease are untold, and conclusions and generalizations are apt to be consequently fallacious.—I am, etc.,

CHARLES P. CHILDE, B.A., F.R.C.S.

Portsmouth, March 14th.

CHRONIC RETENTION OF URINE ARISING FROM PROSTATIC DISORDER.

SIR,—I doubt whether Mr. Herbert T. Herring has told quite the whole story in his interesting paper (March 12th, p. 376). How does he account for the increased frequency of micturition which is a marked symptom of enlarged prostate long before there is anything like 10 oz. of residual urine? I believe the symptom is common before there is any residual urine at all. A majority of men over 60 pass water two or three times each night, which means that they can only hold some 5 or 6 oz. with comfort. It is not overflow from a distended bladder, for a catheter shows little if any residual urine. He says "prostatic resistance is generally augmented by enlargement." Why, then, does the subject of commencing enlargement pass water more frequently? He ought to have to wait until the "tonal bladder pressure" is sufficient to overcome the increased prostatic resistance.

One practical question for the practitioner is, When ought he to insist on passing a catheter? Should he insist if the urine is normal but passed only 3 or 4 oz. at a time, or should he wait until there are some signs of retention? The passage of a catheter is not devoid of danger.

Mr. Herring's treatment seems to me a bit risky. It might be done in hospital, but it would be dangerous in private practice, and a terrible ordeal for both patient and medical attendant. If the catheter is left to the patient "a breakdown in the technique adopted with regard to the preparation and passing of the catheter" is almost certain. The timing of the catheter would be difficult, for the secretion of urine is extremely irregular. Some nights a patient will secrete 20 oz., and on others as little as 4 oz. Most patients would prefer an operation, even a dangerous and tedious one.

If the practitioner succeeds in so increasing the muscular strength of the bladder as to overcome the increased prostatic resistance, surely he is dangerously near the production of back-pressure with fatal results to the kidneys?—I am, etc.,

O. CLAYTON-JONES, M.B. Oxon.

Silverton, nr. Exeter, March 14th.

THE DROOPING SHOULDER SIGN OF PHTHISIS.

SIR,—Let me reply briefly to the little discussion of the paper entitled as above. The first participator says I mention Krönig, but not his "isthmus of resonance." Hardly necessary, perhaps, for that is by way of being a

classic sign, and every recent textbook, British or other, has it.

The second gives a British book in which, he states, the drooping shoulder phenomenon is fully described. I fear I cannot agree. There is no mention of *unilateral* drooping. What is described is sinking of both shoulders due to the long familiar fact that the *thorax paralyticus* has a position of expiration. Nothing is said of one scapula lying lower than its fellow, nothing of this asymmetry being probably due to the atrophic trapezius allowing it to sag; nothing of the probability of such atrophy being an end-stage of Pottenger's muscular spasm and subsequent pulpy degeneration; nothing of the smaller nipple on the affected side confirming the theory of nervous origin of the atrophy by pointing to a possible trophic influence. As there are four lines on lowering of the nipple I do not think the author can have read Krönig's untranslated little masterpiece in the *Deutsche Klinik*, or his ready mind would have appreciated the precedence given there to the *drooping* scapula over the lowered nipple. In this exegesis I am confirmed by his own entry into the discussion. He talks only of lowering of the external end of the clavicle, which he now associates with advanced or extensive disease, citing Walsho to the same effect. Thus it might now possibly be unilateral, although we are left in the dark as to that; but there is nothing even implicit to be gathered as to a connexion with muscular atrophy. In truth, changes in thoracic conformation from advanced lung disease are another thing altogether: witness the frequency of shoulder drooping with clinically early lesions or with the hilius affection of children. Since the bibliography of his book has not a single reference to a German or Austrian paper in the original, while, on the other hand, nearly a third of the articles in it are by Scotsmen, one of them mentioned repeatedly, my withers are not sore under his strictures as to authors and nationalities proper to quote. For my part, I cited the chief relevant writers—Krönig, whom we have heard about; Bandler and Roepke, the English translation of whose book is on every tuberculosis officer's shelf; Schröder and Blumenfeld, authors of the fullest work on phthisio-therapeutics in existence; and the American Pottenger, whom my third critic also cites. To *approfondir* a subject one must forget geography, and that mendacious goddess Politics.

The fourth one, I fear, with every wish for an amicable summing up, I must characterize as another confuser of *thorax paralyticus* with a unilateral phenomenon; as is surely plainly apparent. Even if he were not, two words are a smallish basis for a priority claim. We are not all as easily satisfied as M. Jourdain was when they told him "Bel Men" meant such a lot of things.

The "drooping shoulder" seems always to excite interest. Readers might therefore care to turn up *Tubercle* for July, 1920, where I have traced the analogy with muscular spasm and atrophy in osseo-articular tubercle, and in some cases of scrofula.—I am, etc.,

Barnsley, March 14th.

W. C. RIVERS.

THE CURE OF HAEMORRHOIDS WITHOUT OPERATION.

SIR,—I fear I must ask you to allow me to trespass upon your space again in order to reply to Dr. Lyth's letter in the *JOURNAL* of March 12th. I do not know whether to take his opening remark, in which he accuses me of being a physician and not a surgeon, as a compliment or the reverse, but it is typical of the inaccuracy of observation which he shows all through his letter.

Dr. Lyth admits that my views as to the essential differences between external and internal haemorrhoids are assumed by most authors. But he goes on to quote from Walsham and Spencer's book on *Surgery* to prove that "most authors" are incorrect. This little students' book is hardly one to which to refer in a scientific discussion, and Dr. Lyth is forced to make a very "tall" assumption to support his theory that an internal pile may be converted into an external one. The quotation to which he refers is merely to the effect that some piles are "covered in part with skin and in part with mucous membrane." I cannot see why Dr. Lyth should assume from this that the authors meant to imply that internal piles may ever become completely covered with skin and shift their base from above the anal valves to

the skin outside the bowel, which is what he has to do to show that internal piles may become external. He goes on to mention that Keen describes skin-tags as "false piles," and asserts that these skin-tags are "cured" internal piles. I think that most authors—and certainly most authors of books on rectal surgery—are agreed that these skin-tags result (1) from thrombosed external piles, which have subsided, and (2) from the subsidence of oedematous folds of skin around the anus, which are so commonly associated with—but which are altogether separate from—strangulated prolapsed internal hæmorrhoids. Over and over again I have seen these oedematous skin folds appear after carelessly performed stretching of the anus, and also in cases of semi-strangulated prolapsed piles. These piles can be reduced in most cases, but after their reduction the swollen folds of skin remain, and, after the inflammation and oedema have subsided, they remain as skin-tags. The internal piles remain also (unless operated upon or otherwise treated), and it is obvious, therefore, that the tags are not the external "remains" of internal piles, because the internal piles are still there also.

I can assist Dr. Lyth when he wonders what an "internal pile outside the anus still covered with mucous membrane and yet cured, looks like and feels like." An internal pile cannot be outside the anus covered or not with mucous membrane and yet cured. Its cure can only be assumed when no pile can be seen inside or outside the anus on examination with the speculum and otherwise. The subject of his bewilderment is a confusion of ideas and a contradiction of terms.

It may be that Dr. Lyth has watched more cases of piles than I have, but in view of my three years' experience in the out-patient department of St. Mark's Hospital, and a private practice which has included a very large proportion of rectal cases—and especially of cases of hæmorrhoids—I am disposed to doubt it. I have seen skin-tags arise over and over again in the ways I have described above, and most writers on rectal surgery describe the same processes; but I have never seen an internal pile acquire a skin-covering and an external attachment, nor can I find any writer, other than Dr. Lyth, who has observed such an extraordinary process. When Dr. Lyth goes on to inform us that the glans penis in the uncircumcised is covered with mucous membrane, one realizes that his powers of observation are not very accurate!

I should not have thought it necessary to assert again that internal piles which have never prolapsed may give rise to serious symptoms, had not Dr. Lyth tried to prove the contrary. It is useless for him to repeat his statement that "so long as it is inside and remains inside—even during defæcation—it does little harm." I assume that internal piles inside the anus may bleed, because I have seen them, with the aid of a speculum, actually bleeding and the blood collecting inside the rectum—and this not seldom but very commonly. Such bleeding piles are often far too small to reach down as far as the anus, and when the patients assure me they have never prolapsed, I prefer to believe these patients and my own eyes rather than Dr. Lyth's very dogmatic contradictions.

I cannot follow Dr. Lyth's argument about the shape of the stomach as seen in a-ray examination, because I cannot see what it has to do with what Dr. Lyth assumes is the normal prolapse of the rectal mucosa during defæcation. I have sat behind a horse and am well aware that in that animal there is some prolapse of mucous membrane from the anus during defæcation; but the human rectum does not prolapse during defæcation in a normal individual, though of course piles often do prolapse during defæcation and become reduced spontaneously. In fact, I make a note in every case as to whether the piles are spontaneously reducible or have to be reduced digitally. It is unnecessary to give a patient an enema and to make him strain in the squatting position to demonstrate the presence of piles, if one possesses and knows how to use a good speculum. This process of enema and the squatting posture, suggested by Dr. Lyth by Keen, has obvious disadvantages in private practice, especially if the patient is a lady. I fancy a speculum gives more accurate results and less offence to delicacy.

Dr. Lyth next asks how a pile can bleed externally in any quantity unless prolapsed. It cannot do so, but it

frequently does bleed into the rectum in large and even dangerous amounts. I have seen cases where the accumulated blood has acted as an enema and has been expelled suddenly together with faeces, leaving the patient almost pulseless. And yet in some of these cases the piles had never been down and could not be forced down by straining, even after the enema that was necessary to get rid of the remainder of the blood and faeces in the rectum, and so to inspect the piles *in situ*. Certainly in cases where the piles do prolapse and where bleeding takes place outside the anus, the blood is often small in amount and arterial in colour—in fact, the bleeding is nearly always from small arteries. Dr. Lyth will assuredly come across cases in which there has been no temporary prolapse and there has been serious bleeding nevertheless.

Dr. Lyth charges me with distortion in stating that a patient who has undergone his treatment must afterwards wear a pad and powder the piles frequently. I made no such statement. Quoting from his article, I said that on his own showing it will be some six weeks before the piles can be spontaneously reduced, and that—again according to Dr. Lyth—only then will he be in a fair way towards being "cured." I went on to write: "Meanwhile, and even afterwards, he has to wear a pad, to powder his piles frequently . . ." If Dr. Lyth will refer to his paper he will see that he wrote that it would take two or three weeks for the piles to be sufficiently shrunken to return inside the bowel during the night; after a further lapse of two or three weeks the prolapse is so readily reducible that he may dispense with the pad at night, and he is "then in a fair way to being cured . . ." and he is wise to have calamine and a pad available." I do not think that what I wrote is a distortion of this description, but I do think it is a distortion on Dr. Lyth's part to try to make me out as having said that the pad and calamine must be used after the end of the treatment—presumably ever after; I said no such thing, and therefore plead not guilty to the charge Dr. Lyth makes against me.

On the other hand, I for my part accuse Dr. Lyth of distortion of my description of the results of the treatment by injection when he says that I implied that the result as far as symptoms are concerned is not instantaneous. I wrote that in the very large majority of patients both bleeding and prolapse have disappeared from the moment of the first injection. My criterion of the cure of piles is not their disappearance from view into the rectum and the cessation of symptoms, but the complete absence of piles on inspection of the interior of the rectum with a speculum. To ensure this, an average of four injections at weekly intervals is necessary; sometimes one attains this result with two and sometimes as many as six are necessary. Dr. Lyth calls a *maximum* of six "injecting for an indefinite period," and tries to make out that the symptoms continue all that time, which, as I have said, is a distortion of what I wrote.

A very conservative estimate of the number of injections I gave at St. Mark's Hospital would be 1,500, and I suppose that I have treated not less than 1,000 cases in my private practice. Amongst these there have been no cases of pyæmia or of hepatic abscess, and I have not heard of any case of this sort in the practice of others. I have heard of pyæmia in cases treated by operation in the old septic days, and also of cases of abscess and pyæmia following upon sloughing of strangulated piles, left untreated or "treated" without reduction by so-called palliative measures. I can well imagine that if injections were given with septic instruments and without careful attention to details such complications might arise; but the same may be said of operative, palliative or any other treatment. I may add that I have many times treated patients by injection after several unsuccessful operations by other surgeons, and that some of these were included amongst the 83.4 per cent. successful injection cases of over three years' standing to which I referred in my former letter.

Let me ask Dr. Lyth to get a Kelly's speculum and examine some of his so-called cures with it in order to ascertain whether they still have piles or not. Let him also give us some figures as to the number of his cases and the percentages cured according to the criterion of whether they still have piles inside the rectum. This evidence is essential in order to form a judgement of the value of his treatment.—I am, etc.,

ARTHUR S. MORLEY, F.R.C.S.
London, W.C., March 12th.

"CHANGE OF AIR."

SIR,—The very interesting article by Mr. Frank Coke in the *JOURNAL* of March 12th, and his demonstration that other things than air are involved in the therapeutic influence of what we call change of air, prompts me to recall a case I saw long ago. A lady under the care of Dr. George Hunter suffered from a chronic irritation on her hands which became intolerable but at once disappeared when he sent her away for change. She came home full of gratitude, but the rash began to develop itself again immediately. At this time *Primula obconica* was discovered (by Dr. W. G. Sym, I think) to be a cause of skin irritation, and Dr. Hunter found she had it in her greenhouse. He banished it, and she was free of the rash ever after. This was years ago, but I have always felt since that the easy ascription of disease to climate was a mistake, and that it was not climate, but associated agencies, which caused the so-called "climatic diseases," and I fancy every one thinks so now. Mr. Coke's research gives prospect of cure to many sufferers.—I am, etc.,

Southsea, March 13th.

W. E. HOME, M.D.

RISKS AFTER OPERATIONS ON TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—I have been so interested in the correspondence in the *JOURNAL* on this subject that I cannot refrain from giving my experience in the special department of a London general hospital—Charing Cross—where the number of beds is seriously limited.

The following routine is adopted: Printed directions for the preparation for operation and treatment are given, and, if that indispensable hospital officer the almoner and her staff find that the patient's home is poor, unsuitable, and not within an easy journey to the hospital, admission is recommended. The operation is performed at 8.30 a.m., and while the child is being prepared the temperature is taken, and if it is above 99° F. operation is postponed. After operation the patient is kept warm and quiet until 12.30, and, if found well enough after inspection by the medical officer, a piece of gauze is fixed over the mouth and the patient sent home. In most cases the mother willingly spends a few shillings on a taxi. The use of an ambulance car was offered, but it was found to be impracticable, as the children lived at all points of the compass. A district nurse visits the patient next day when necessary.

We came to the conclusion that if these patients were to receive any benefit from admission, they must be kept in for at least three days, and it is better for the child to go home a few hours after operation than on the next day after it has had a restless night and the usual reaction with its accompanying temperature.

This routine has been carried out for fifteen years with such good results and without a single serious disadvantage that I am convinced that under the above conditions the hard-and-fast rule that all cases of this operation should be admitted is unsound and impracticable. The question of admission should be left to the discretion of the individual operator, who, with a little tact, can obtain any and every thing for his majesty the child.—I am, etc.,

London, W., March 11th.

EDWARD D. D. DAVIS.

THE FALL IN THE TUBERCULOSIS DEATH RATE.

SIR,—It is to his little controversy with me that Dr. Davies's letter (February 26th, p. 322) refers. It is so earnest, and its fallacies so pathetic, that criticism may seem ungracious. But he will allow that truth is to be sought at all costs; and that a man may be seeking the same aims with himself who tries to find out what are the limits within which the State can do good, without which it must do harm.

He and I start from a common basis in regard to the effect on real wages of Insurance Acts and the like. As he implies, they lower them. But, he maintains, such measures may do much to stamp out phthisis.

It would be difficult to find a more crushing refutation of his position than has been afforded by the seven years 1913-1919. To begin with, destitution, on which he laid and lays much stress, was abolished during the war, and much diminished, as he said, before the war. The death

rate went up. State agencies were working at the minimum of impediment up to 1915. The death rate rose. After that they worked with a gradual increasing impediment up to the maximum in 1918. According to the Registrar-General, but for the influenza epidemic at the end of 1918, it would have been obvious that the rate was declining in 1918; the decline was patent in 1919.

Dr. Davies rather plumes himself on his prophecy, vague and faltering though, on his own showing, it was. Let me tell him what were the prophecies of men of my school. In 1912 we predicted a rise in 1915, due to the Insurance Act. That came true. In 1915, seeing how money wages were outstripping prices, and assuming, as we had learned to assume, that the war would last for so long, we predicted a fall in 1918. The Registrar-General cannot be accused of standing on the same platform with me, and he says that prophecy came true also. If history goes for anything, the momentum of that fall will last another year or two. But the question of wage rate is to-day extraordinarily complex. No one can predict its course with any confidence. Personally I believe that real wages are falling, and must fall considerably in the near future. If so, one fears that we have to look to a rise in the rate in 1923.

But in any case the fall in 1919 (which is partly unreal, for clearly many deaths occurred in the last quarter of 1918 which normally would have fallen in 1919) of phthisis mortality is short of that of 1913. It is humiliating to find that we have made no progress in six years; nay, if I take a single year—namely, 1918 (as he does)—none in twenty-six years. But my point was, and is, the slackening of the rate of fall from 1895, since statesmen discarded Gladstonian finance. If the Gladstonian rate of fall had been maintained, in 1919 the death rate would have been some 400. It was some 1,000; and that only after a little jugglery.

I submit that there is only one possible explanation of the facts of the war—namely, the raised standard of living among the largest section of the community, the borderland class. I am constantly seeing statistics that show that after the momentum of the rise due, finally, to the Insurance Act, had died down, the insurance class of patient died less fast than before, though in 1917 and 1918 conditions were at their worst. On the other hand, classes which had been well-to-do had their standard lowered, and died faster. It is highly significant, for example, that half the increase in deaths in 1918, were asylum deaths—that is, of people who would not feel the fluctuations in wages rate, but would be specially obnoxious to debilitating influences, such as inferior food, though again they would be exceptionally fortunate in the degree of official supervision they enjoyed.

If Dr. Davies is to prove his point, it is imperative that he should adduce instances of a fall in the rate after a fall in real wages. I have sought earnestly and cannot find one, though I can show scores where a fall in rate has been heralded by a rise in wages, or a rise in rate by a fall in wages. All the benefits he aims at obtaining for the poorer classes—with the exception of the army of officials—come automatically if the rate of wages rises. Indeed, he himself lays stress on a raised standard of living. It plainly cannot be raised unless wages are also raised. The official naturally sees the result for good on individuals of measures of the kind we were discussing; he ignores, because he does not see, the results for evil on the mass. But we, who go habitually and intimately among the poor, know that for one relieved twenty suffer.

The State has had to compete with private capital for labour, and so wages have been raised by help of loaned capital to an undreamed-of height. That cannot go on. But the process can be wholesomely imitated, and in one way only—the way of Mr. Gladstone and the Manchester School. Let the State and municipality stay their mischievous hand.—I am, etc.,

Releigh, Essex, March 5th.

B. G. M. BASKETT.

THE PREVENTION OF VENEREAL DISEASE.

SIR,—In considering this problem we cannot disregard the facility with which brothels are established and conducted in London.

As a member for six years of the Legal and Parliamentary Committee of the Council for this borough I realized (1) that this evil is extensive and carried on by

Smethwick, March 7th.

Obituary.

ERNEST HOOK BUCKELL, J.P., M.R.C.S., L.R.C.P.,
Consulting Physician, Royal West Sussex Hospital.

DR. E. H. BUCKELL, who died at his residence in the West Pallant, Chichester, in his 69th year, was the second son of the late Dr. Leonard Buckell, of the same city, and came from a generation of members of the medical profession. He was educated at Epsom College, after which he had a distinguished career at University College Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. and L.S.A. in 1875. Thenceforward he practised in Chichester and the district, succeeding his father as medical officer of the Bishop Otter Memorial College and of the Chichester Poor Law Institution. He enjoyed also an extensive private practice. For over thirty years he was honorary physician to the Chichester Infirmary, now the Royal West Sussex Hospital. On his resignation, in 1919, he was appointed hon. consulting physician. He founded the x-ray department at that hospital, and its present state of efficiency is due to his work of some years ago.

Dr. Buckell was a great supporter of the British Medical Association, and in the year 1919 was President of the Chichester and Worthing Branch, and as such entertained the members at his house in July of that year. As a colleague he was exceptionally agreeable. His sympathies were always extended to the poor people of the city, and on this account he will be greatly missed. His personal relief to people in the district was extensive and his devotion to duty was great. Dr. Buckell took a keen interest in public affairs, and was for many years a member of the City Council and also a Justice of the Peace for the city. His spare time was given up to carpentering, in which art he was an expert. To mourn his loss he leaves a widow and four daughters (one of whom married Dr. Walter Dick, who succeeds to his practice) and two sons, Dr. Ernest Buckell, who practices at Newport, Isle of Wight, and Dr. Aston Buckell, who is assistant bacteriologist at Durham University.

DR. HUGH A. MCCALLUM, Emeritus Dean of the Western University Medical School, London, Canada, died of pneumonia on January 25th after a brief illness. He was born near London, Ontario, in 1860, and was educated at the Collegiate Institute, St. Thomas, and at the Western University Medical School, from which institution he graduated in 1886, winning the gold medal. After acting as lecturer in biology for the session 1886-7, he proceeded to Johns Hopkins University, where he studied physiology under Newell Martin. On his return to his native town he was appointed professor of physiology, a position he held for the succeeding ten years. During this period he wrote extensively on physiological topics, his papers being marked by much originality and philosophic grasp. He was subsequently appointed to the chair of medicine and continued in that post until last year. In 1906 Dr. McCallum came to England and studied at various London hospitals, obtaining the membership of the Royal College of Physicians of London in the following year. In 1913 he was elected Dean of the Medical Faculty of the Western University, and under his influence the medical school entered on a new era of prosperity; full-time professors were secured for the laboratory departments, and the project for obtaining new buildings assumed definite form. The commodious and efficient medical laboratories now nearing completion represent the culmination of his efforts in behalf of medical education in Western Ontario. He was appointed emeritus dean in 1919. In 1901 he married Miss Mary Burnard; he is survived by his widow, three sons, and one daughter. The high regard in which Dr. McCallum was held, both professionally and personally, made him a great force, not only in his own community, but in Canada generally. His death was deeply mourned by people in all stations in life.

DR. DONALD JOSEPH MACAULAY of Halifax, who died on March 8th, received his medical education at the University and the school of the Royal College of Surgeons of Edinburgh. He took the triple Scottish qualification in 1890 and the M.D. Brux. in 1897. He was a native of the Outer

Hebrides, but had resided in Halifax for thirty years, where he had a large practice and was greatly esteemed by his patients. He took great interest in the work of the St. John Ambulance Association, of which he was a life member. He was a member of the British Medical Association and had held the office of President of the Halifax Division. One of Dr. Macaulay's chief hobbies was to collect Whistler's etchings, of which he had an excellent collection. He is survived by his widow, three sons, and two daughters.

WE regret to announce the death from pneumonia, at the age of 67, of Dr. JOSEPH ERNEST BULLOCK, of St. Leonards-on-Sea, which took place at Northampton on March 4th. Dr. Bullock was educated at University College Hospital; he qualified M.R.C.S. and L.S.A. in 1878, and obtained the M.D. Brux. in 1880. He was subsequently resident medical officer at the Western Medical Dispensary, London, and house-surgeon at St. Peter's Hospital. After practising for many years at Ladbroke Grove, W., he took up the special study of tuberculosis, and he was for some time on the staff of the Eversfield Chest Hospital, St. Leonards-on-Sea. During the later years of the war Dr. Bullock was employed as acting tuberculosis officer for the county of Northampton. He translated Cornet's *Skrofulose* with marked success, and he wrote numerous articles which were published in the medical journals. He was recognized by all who knew him as a man of the highest character, with a kindly nature, and a varied and extensive knowledge of medical work.

THE untimely death of Captain (Temporary Major) EDWARD RANDOLPH ARMSTRONG at Quetta at the early age of 36 removes from the I.M.S. one of its most capable and popular officers, and one who—health permitting—would have undoubtedly gained high honours and rank. Armstrong had a brilliant academic career. He took the Liverpool University M.B., Ch.B. degrees with honours in 1907, and subsequently the M.D. while at home on sick leave. In 1909 he took the D.T.M. Liver. and in 1910 the D.P.H. Camb. with "distinction" in three of the four subjects. Joining the Indian Medical Service in July, 1911, he won all the prizes open in his term to the I.M.S. and the I.M.S. and R.A.M.C. combined. At the beginning of the war he was invalided to England on account of ill health. Having been passed fit for duty in India—but to his sorrow not for general service—he returned to India in 1916, and was appointed D.A.D.M.S. (Sanitary) at Army headquarters. The work entailed by this appointment he carried out in a highly efficient manner for nearly four years. After a few months spent in England he was appointed D.A.D.M.S. (Sanitary) of the 4th Quetta Division, and took up his duties in December, 1920. A colleague writes: "Though a rapid worker everything he touched showed meticulous care. Often in ill health, he never allowed personal affairs to interfere with the strenuous and responsible work he was called upon to do. He never worried—difficulties only added zest to his work. Kind-hearted, generous, and lovable, the many friends to whom he endeared himself will long remember him."

THE death has occurred at Bratton, Wilts, of Dr. CHARLES A. GATLEY, at the age of 31. The son of Dr. H. R. Gatley, of Kingston-on-Thames; he was educated at Marlborough and Guy's Hospital, where he held the post of house-surgeon. On the outbreak of war he went as house-surgeon in charge of Mrs. Hall-Walker's (now Lady Wavertree) hospital at Regent's Park, and a year later went to France, attached to the East Kent Regiment. It was while at Cherisy that, in 1917, he was very severely wounded, and the results brought about his early death. He was wounded while going up to the firing line, because the stretcher cases were not coming down quick enough. In April, 1919, he entered into partnership with Dr. Trevor Shorland, of Westbury. Dr. Gatley was only recently appointed medical officer for the Bratton district under the Westbury Guardians, and was a member of the Pensions Board for Wiltshire. The burial took place at Bratton, Dr. Bond of Trowbridge representing the Wiltshire Branch of the British Medical Association.

The death is announced at Ballarat, Australia, on January 24th, of Dr. WILLIAM MORRISON, youngest son of the late Mr. Donald Morrison, LL.D., a former Rector of Glasgow Academy. Dr. Morrison graduated in arts at Glasgow University in 1877, and in medicine in 1881, taking the degree of M.D. three years later. He was, senior honorary physician of Ballarat Hospital, and physician-acoucheur to Ballarat Female Home. He held the rank of major in the Australian Army Medical Corps.

Dr. JAMES ARTHUR WILLIAM CULLEN died at the British Station Hospital, Jhansi, India, on January 16th. He was educated in Dublin, where he graduated B.A., M.B., B.Ch., and B.A.O., in 1917, and immediately took a commission in the Special Reserve of the R.A.M.C., being promoted to captain on October 10th, 1917. He had served in India. On being demobilized last year, he entered the service of the Great Indian Peninsular Railway, and at the time of his death was district medical officer at Bina.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN Ordinary Council was held on March 10th, with Sir Anthony Bowlby, President, in the chair. Diplomas of Fellowship were granted to nineteen candidates found qualified at the recent examination. Licences in Dental Surgery were granted to thirty-eight candidates found qualified at the recent examination. Mr. H. J. Waring was appointed Bradshaw lecturer for the ensuing year.

The Dentists' Bill.

The following report of the Dentists Bill Committee was presented to the Council:

As requested by the Council on February 10th, 1921, the Committee has taken into consideration the bill to amend the Dentists Act, 1878, presented to Parliament by Dr. Addison, and has consulted the Dental Section of the Board of Examiners in Dental Surgery in reference thereto. So far as the Committee has been able to ascertain, the bill, as a whole, is approved by most members of the dental profession. There is, however, one provision in the bill which meets with some amount of opposition, the provision to admit to the profession without any kind of test persons who for five years immediately preceding the commencement of the Act have been engaged in the practice of dentistry. It is strongly felt by many that no one, who has not passed some sort of examination as a test of fitness, should be put on the *Dentists' Register* itself, and that vested interests would be sufficiently met by placing those who have been in practice for five years or more on a separate list, appended to the *Dentists' Register*, with the title of dental practitioner, and with the right to pass to the *Dentists' Register* if they submit themselves successfully to the prescribed examination. At the same time it is recognized that it might be undesirable to adopt this course unless those placed on the separate list could be made subject to the same control as those on the *Dentists' Register* itself. There are some provisions in the bill to which the Committee thinks it desirable to call the attention of the Council. In addition to the fee for original registration, the Board which it is proposed to set up will have power to charge an annual fee, not exceeding £5, for the retention of a name on the *Register*. Further, while the actual order for the erasure of a name from the *Dentists' Register* will be made by the General Medical Council on a report from the Board, the inquiry in connexion with the removal from or restoration to the *Dentists' Register* will be held by the Board. As any name erased from the *Dentists' Register* on account of crime or disgraceful conduct must also be erased from the list of licentiates in dental surgery or dentistry of the medical authority of which such person is a licentiate, it follows that a licentiate in dental surgery of the Royal College of Surgeons may be deprived of his licence after judgment by this Board on which the College is not represented. As regards the constitution of the Board, the Committee finds that, as at first constituted, 9 of its 12 members will be appointed by Government authorities, and that both in its initial and its permanent form no representation is given to the medical corporations, and not less than one-half of the seats on the Board are allotted to representatives of Scotland and Ireland. The want of proportion in this arrangement may be gathered by reference to the official statistics published in the *Dentists' Register* for 1920, which show that 80 per cent. of the persons

whose names are recorded in the *Dentists' Register* are graduates and licentiates in dental surgery of universities and colleges in the United Kingdom, and that of these approximately 50 per cent. have qualified in England, including 46 per cent. holding the licence in dental surgery of the Royal College of Surgeons of England, 21 per cent. have qualified in Scotland, holding, with two exceptions, the licence in dental surgery either of the Royal College of Surgeons of Edinburgh or of the Royal Faculty of Physicians and Surgeons of Glasgow, and 9 per cent. have qualified in Ireland, all but thirty holding the licence in dental surgery of the Royal College of Surgeons in Ireland. The Committee further note that the Board, both in its preliminary and its permanent form, is to contain three lay members, not being registered medical practitioners or registered dentists.

The Committee thought it desirable to call the attention of the Council to several points in connexion with the bill, but, while unable to regard it as entirely satisfactory, is not prepared to recommend the Council to endeavour to secure any amendments, in view of the general acceptance with which it appears to have been received by a majority of the members of the dental profession.

Election of Council.

A meeting of the Fellows will be held at the College on Thursday, July 7th, at 2.30 p.m., for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir George H. Makins, G.C.M.G., C.B., Mr. J. Ernest Lane, Mr. H. J. Waring, and Mr. F. F. Burghard, C.B. Blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the Secretary, and the same must be received by him duly filled up not later than Monday, March 21st. A voting paper will be sent by post to each Fellow whose address is registered at the College, on April 5th. Fellows are requested to give notice, without delay, of any change of address, so that their voting papers may not miscarry. We are informed that Sir George Makins and Mr. Ernest Lane will not present themselves for re-election.

UNIVERSITY OF OXFORD.

Osler Memorial.—At a public meeting held in March, 1920, it was decided to raise a fund to establish a memorial to the late Sir William Osler, Bt., Regius Professor of Medicine in the University. The fund has now reached nearly £2,000, and a further list of subscribers will be published soon. Subscriptions may be sent to the Honorary Treasurer, Mr. A. P. Dodds-Parker, B.M., F.R.C.S., 2, Holywell, Oxford.

Diploma in Public Health.—The Board of the Faculty of Medicine gives notice that at the examinations for the diploma in public health in Michaelmas Term, 1921, and afterwards, the first part of the examination will comprise the application of chemistry and physics to general hygiene, and general pathology with special relation to infectious diseases. The second part will comprise practical pathology and bacteriology, general hygiene, the application of public health, sanitary engineering, and vital statistics. The examination will be held in Michaelmas Term, 1921, will be held on March 9th, 1921 (Clarendon Press, Oxford). This announcement is to remove from the examination in systematic pathology and bacteriology, but to retain in Part 2 a practical and viva voce examination in those parts of the subject which are most closely related to public health.

Degree Days.—The following degree days are announced: Saturday, March 19th, at 10 a.m.; Thursday, April 28th, Saturday, March 19th, at 10 a.m.; Thursday, April 28th, Saturday, May 21st, Thursday, June 16th, Thursday, June 23rd, and Saturday, July 9th, at 2.30 p.m.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The following have after examination been admitted as Fellows of the Faculty: S. S. Barton, R. T. Grant, N. Morris, J. Russell.

The Services.

The following members of the Scottish Women's Hospitals for Home and Foreign Service have received the King's permission to wear decorations of the Order of St. Sava of the classes conferred upon them by the King of the Serbs, Croats, and Slovenes in recognition of their services to the Serbian sick and wounded in the late war:—*Fourth Class*: Miss Beatrice Anne McGregor, M.B., C.M. *Fifth Class*: Miss Lillian Mary Chesney, M.B., Ch.B., Miss Janet McVea, M.B., C.M., Miss Elizabeth Brook, M.B., Ch.B., Miss Catherine Louise Corbett, M.B., Ch.B., Miss Janet Stewart Laird, M.B., Ch.B.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL ROBERT CONN, Bengal Medical Service (retired), died at Lincoln on January 15th, aged 63. He was born on May 10th, 1852, the son of the late Rev. T. Cobb, of Stockbury, educated at University College, London, and took the diploma of M.R.C.S. in 1874 and L.R.C.P. Lond. in 1875, and subsequently

the M.D. Brax. In 1886 entering the I.M.S. on March 31st, 1876, he became surgeon lieutenant colonel after twenty years' service, and retired on October 10th, 1906. His whole service in India was spent in civil employ in Bengal, where he held two of the most important stations, Patna and Dacca, successively, and also acted as Surgeon Superintendent of the Presidency European General Hospital, Calcutta. Some years after he retired from the army he entered the service of the British North Borneo Company, under whom he served as Principal Medical Officer and Member of the Legislative Council at Sandakan, the capital of the Protectorate. He had only recently retired and returned home.

Dr. William Frederick Abbott died at Chilton on February 23rd, aged 63. He was educated at the Leitch School, Dublin, and took the L.R.C.S. and the L.R.C.S. Ed. in 1884. Before the war he was in practice at Clapham, he took a temporary commission as lieutenant in the R.A.M.C. on April 7th, 1915, becoming captain after a year's service, and acting major on March 29th, 1918; he was medical officer to the Military Hospital, Lewisham, demobilized a year ago.

Medical News.

ON the recommendation of the Minister of Health, the King has been pleased to appoint Mr. C. L. Leicester Walker, M.P., to be a Commissioner (unpaid) of the Board of Control, in the place of the Right Hon. Sir W. H. Dickinson, K.B.E.

WE are asked to state that hospitals in the county of London, or within nine miles of Charing Cross, desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1921, must make application before March 31st to the Honorary Secretaries, 7, Walbrook, E.C.4. Applications will also be considered from convalescent homes which are situated within the above boundaries, or which, being situated outside, take a large proportion of patients from London. Applications will also be considered from sanatoriums for consumption which take patients from London, or which are prepared to place beds at the disposal of the Fund for the use of patients from London hospitals.

A SPECIAL post graduate course adapted to the needs of the medical man in active practice will be held at the Prince of Wales's General Hospital, N.15, from Monday, April 25th, to Saturday, May 7th. It will include each day demonstrations of clinical and laboratory methods in the morning, and in the afternoon demonstrations of groups of selected cases, and either a clinical lecture or clinical consultation. Demonstrations will also be given in association with special hospitals. A syllabus, to be issued in due course, will be sent on application to the dean.

THE annual conversation of the Middlesex Hospital Medical Society will be held at the hospital on Monday, next, March 21st, at 8.30 p.m. Dr. Charles Singer will deliver an address entitled "Medicine in Ancient Greece."

THE list of products covered by the Denatured Spirits (Regulation) Act, which has been published by the Board of Trade, Industries and Manufactures Department, Great George Street, Westminster, London, S.W.1.

THE annual meeting of members of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Tuesday, April 5th, at 5.30 p.m.

A SPECIAL meeting of the Röntgen Society will be held at Manchester, on Friday, May 6th, 1921, at 8 p.m., at the University, when Professor W. J. Bragg will deliver a paper and Professor A. V. Hill will give a demonstration of some electro-physiological experiments. On the following day it is hoped to arrange visits to works of scientific interest in the district. As this will be the first meeting away from London, it is hoped that as many members as possible will attend in order to make the meeting a success. The gallery of the Royal Photographic Society of Great Britain has been placed at the disposal of the Röntgen Society during June, when it is hoped that a collection of radiographs, illustrating the different practical applications of x-rays, will be furnished by members of the Society.

THE Wellcome Historical Medical Museum will be closed for redecoration and cleaning from April 1st to the 30th, inclusive.

THE annual debate of the Chelsea Clinical Society, which had been fixed to take place this month, has been postponed till April 19th.

THE house and library of the Royal Society of Medicine will be closed from Thursday, March 24th, until Tuesday, March 29th, both days inclusive.

IN accordance with the terms of the will of the late Dr. Robert Thomas Nichols, the Royal Society of Medicine will offer every three years a prize of £250, open to any British subject, for the most valuable contribution towards the discovery of the causes and the prevention of death in childhood from septicaemia. Work already published may be submitted provided it at the date of publication is subsequent to June 30th, 1921. The first award will be made in 1924, and the application must reach the secretary of the Society not later than June 30th, 1921.

DR. H. E. DIXON of Malvern, and Major J. R. Williams, T.D., have been appointed sheriffs for the counties of Worcester and Cornwall respectively.

THE Colston University Society was founded twenty-two years ago, and on the incorporation of the University of Bristol in 1909 it was resolved to apply the funds of the Society to the support of research work within the University. In order to make it clear that the Society exists for the support of research work within the University, and that its funds are devoted wholly to this purpose, the title has now been changed to the Colston University Research Society.

DR. EDUARD B. PANKER of Neuchâtel, Switzerland, well known for his work on tuberculin, has recently died.

Letters, Notes, and Answers.

As, on no printed difficulties, the JOURNAL must be sent to press earlier than it is essential that communications intended for the current issue should be received by the post on Tuesday, and reaching the printer on Monday.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary is stated.

Correspondents who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring replies of their articles published in the British Medical Journal are requested to communicate with the Office, 42, Strand, W.C.2 on receipt of proof.

In order to avoid delay it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the British Medical Association, and British Medical Journal is 42, Strand, London, W.C.2. The telegraphic address are:

EDITOR of the British Medical Journal, Littlewood, 42, Strand, W.C.2.
AND BUSINESS MANAGER, Westland, London, telephone,

42, Strand, W.C.2. Telegrams: Westland, London; telephone 2330 Gerrard. The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams: Dublin). Dublin telephone 4737, Dublin and of the Scotch Office, 6 Rutland Square, 1 Dundee (telegrams: Deccate Edinburgh, telephone 4561, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"X Y Z" is a retired medical officer and possesses a house in Ireland. If he lets that house furnished for seven months of the year, or for the whole year, is he liable for income tax on his pension or colonial dividends, provided that he then lives outside the United Kingdom?

* The facts are unusual, and the point arising does not seem to be precisely covered by a decided case. In our opinion "X Y Z" would be liable (a) in respect of income arising in the United Kingdom—for example, the profit on the furnished letting, and (b) on the amount of retired pay or colonial dividends remitted to the United Kingdom. Residence outside the United Kingdom, while another residence is not maintained there, would exempt our correspondent, but it is a settled principle of law that a man may have more than one residence simultaneously, and the possession and occasional use of a furnished house might constitute "residence" for the purpose of the Income Tax Acts.

SEA WATER FOR INTERNAL USE

"Medoc" writes: In answer to "Haloid's" query (March 5th, p. 369) there is a preparation of sea water, rendered isotonic with the blood, which is sterilized and put up in sealed glass ampoules in various quantities. It is usually given intramuscularly, but can be taken by mouth, diluted with ordinary water. It is procured twenty miles from shore at a minimum depth of 30 ft. The sea water is sold by Messrs. A. Nelson and Co., 73, Dale Street, Grosvenor Square, W., and by Messrs. Sumner and Co., 40, Hanover Street, Liverpool. The former supply comes from France and costs rather more.

CHILD BIRTH AND LACTATION.

CHILD BIRTH AND LACTATION.
DR. JOSIAH OLDFIELD writes from Darliston, Jamaica: In this age, when women are so apt to wish to avoid "the pains and perils of childbirth," it is pleasant to record that here in Jamaica the advent of a baby is not preluded by anxiety nor accompanied by difficulties. The negro woman is strongly and stoutly built, her limbs are rounded, shapely, and symmetrical, her spine is straight, and her carriage erect, and women regularly walk distances of ten to thirty miles, carrying loads on their heads of from twenty to sixty pounds. Their total clothing is a loose cotton dress and a pair of cotton drawers, with a handkerchief round the head. Their diet is chiefly yams, sweet potato, sugar cane, banana, orange, breadfruit, beans, and rice. It is important to note that in this dietary the nursing mother has always an ample supply of milk, and that artificial feeding of babies is almost unknown.

A MODERNIZED DRUG LIST.

MESSRS. ALLEN AND HANBURY have issued to the medical profession a well-produced, little book entitled *Medicines Recently* containing an alphabetical list of the articles manufactured by the firm, with particulars of their composition and dosage. An improvement from the point of view of utility might be to increase the number of cross-references, as the busy practitioner is apt to forget the trade-mark names of articles; for instance, we cannot trace the brand of hydrogen peroxide, which we know the firm manufactures, under either "hydrogen" or "peroxide," while suppositories also are hidden away under some other name.

A TALL TALISMAN.

WE have received from an I.M.S. officer a delightful business circular, issued in all seriousness by a native firm in Calcutta, advertising a "Talisman" which they manufacture. We quote from the circular: "By its use (by its use means simply wearing it round the neck, waist, or arms) one will be freed from all disease, all will be blessed with success in every thing and in every act. It prevents untimely death and early decrepitude. A man is sure to get rich within the shortest possible time whether he is engaged in service, commerce, trade, arts, etc., if he prefers to wear one of the wonderful Talismans. It is sure to make him happy and blessed by surrounding him with a merry group of healthy children and beautiful and faithful wife." The testimonials printed are even more ingenious than this exordium. In every case the full name and address of the writer is given. One gentleman writes: "Allow me to tender my heart-felt thanks for the good that you have done to me. I passed this year under great examination." Another: "After the usual examination by my uncle, Mr. — of — Hospital, has received Honours from Government." An official: "On the very next day on wearing your Talisman my pay was increased by 100 Rs. The effects are wonderful." Another official: "I cannot find words to express the efficacy of your Talisman. My circumstances in pecuniary matters were really bad, and there has been marked improvement." Health is improved as well as the pocket. One gentleman in an official position writes: "I derived much benefit from your Talisman, which cured insanity of my wife, who was suffering from it for the last 15 years. Send another!" Another official: "Your wonderful Talisman has completely cured my son from all diseases. He looks now in colour like lotus flower and strength like Bheema." This wonder-worker can be obtained at the low figure of one rupee four annas, or, in a gold cover, five rupees.

L. W. H., aged 32. Had three brothers. Father member of family of ten. Supernumerary nipple below left breast.

I have evolved a theory in these cases which may be of interest. The grandparents had large families; this was borne out in all the cases which I investigated; in the first two cases I did not inquire. The parents had small families; this was apparent in five out of the six cases. The exception was in No. 5; in which case both parents were members of large families. It would seem as if Nature were making a special effort, in the third generation, to make up for the delinquencies of the second generation in the matter of procreation—by giving an accessory nipple to the male!

DR. WALTER G. WALFORD (London, N.W.) writes: There is one thing that has occurred to me as regards the death of Mabel Weightman, recently found lying on some sacks of fresh cement in an unfinished house at Bushey, and where no apparent cause was discoverable. Many years ago a sack of fresh Portland cement was placed in a small outhouse in my premises. Next day I found a large healthy-looking cat coiled up, apparently asleep, on the top of the sack, but in reality dead. It at once occurred to me that as fatal results often follow, when people sleep in lime kilns, from the emanation of carbonic dioxide, that recent cement, which is largely a compound of lime, might give off small quantities of the same gas, and have asphyxiated the cat in its sleep. Now, possibly the young girl may have gone into the probably un-ventilated room where the six sacks of cement were to wait for someone. If my supposition is correct, the CO_2 would make her drowsy. What, then, would be more natural than that she should lie down on the sacks and, finding her breathing difficult, loosen her corset? And this was how she was found. It would be interesting to know if cement does exhale CO_2 , and if similar accidents have been noticed.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and *locum tenencies* at pages 32, 33, and 34.

THE appointments of certifying factory surgeons at Mauchline (Ayrshire) and Oldham (Lancashire) are vacant.

**SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.**

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line ...	0	1	8
Whole single column (three columns to page)	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	3	0

• An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NORR.—It is against the rules of the Post Office to receive post-
resante letters addressed either in initials or numbers.

MEDICAL EXAMINATION OF RECRUITS.

Dr. G. G. G. (Desborough) writes: Now that a special effort to secure recruits for the Territorial Army, a question of remuneration for the examination of such men will be of importance to many practitioners. I was asked to deal with any possible recruits in my area and was offered the enticing fee of 2s. per man! The forms to be filled up in duplicate can quite successfully vie with those required for a life assurance proposal. Could not the Association take up this matter with the War Office with a view to fixing a reasonable fee for such examinations?

MEDICINE.

332. The Influence of Athletics on the Heart

DEBICHEN (*Acta Medica Scandinavica*, January 14th 1921) gives the results of systematic examinations of the heart of athletes before and after the 50 kilometre ski race at Holmenkollen. Since 1883 these competitors have been medically examined, and since 1914 this examination has been conducted on searching lines—weight and height, position of apex beat, cardiac dullness, heart sounds, pulse, blood pressure, and urine, as well as vital capacity, being investigated with a view to noting changes effected by the prolonged strain of the race. Of 225 competitors, 8 showed an outward displacement of the apex beat after the race, and in 2 the cardiac dullness had extended inwards. In 30 there was a distinct inward displacement of the apex beat after the race, and in some whose apex beat was not distinct before the race it showed distinctly after it, but was always within the nipple line. None of the 8 men with outward displacement of the apex beat after the race showed any sign of cardiac failure, and the condition was almost certainly not due to dilatation. Nor could a history suggestive of dilatation be obtained in those who fell out during the race. The urine of most contained albumin after the race, blood cells, urobilin, and granular and hyaline casts, were also common finds, but there was only one case of definite haematuria. After giving details of many other lines of investigation, including the after histories of these athletes, the author comes to the conclusion that long distance ski racing, as conducted in Norway, has no immediate or remote ill effect on the heart.

333. An Epidemic of Barlow's Disease.

GIORGI (*La Pediatria*, January 15th, 1921) describes an outbreak of Barlow's disease which occurred in Venice at the end of 1919 and first half of 1920. All the cases showed the classical triad of symptoms—namely, anaemia, characteristic changes in the bones, and scorbutic gingivitis, except two in whom the gingival lesions were absent. In almost all the children the typical symptoms of Barlow's disease were associated with rickets. In one case rickets was combined with the spasmodic diathesis. In all the cases dietetic treatment, which is the most valid proof of the diagnosis of Barlow's disease, was successful. This disease is rare in Italy, not only because up to a few years ago artificial feeding was rare in that country, but because patent foods were not so popular as at present. All the children in the epidemic described by Giorgi belonged to the working classes, and had been fed for a prolonged period on a special form of condensed milk which had entirely taken the place of fresh milk in Venice.

334. An Outbreak of Tinea Tonsurans due to *Microsporon lanosum*

CORNAY (*Rev. med. Suisse rom.*, November, 1920) reports an epidemic which occurred in a children's home at Lausanne of twelve cases of tinea tonsurans due to the *Microsporon lanosum*, a ringworm of animal origin. A remarkable feature of the outbreak was the low degree of infectivity of the fungus. Had the *Microsporon audouinii*, the most frequent causal agent of ringworm, been responsible, many more children would have been infected. A ringworm of animal origin cannot be distinguished from *Microsporon audouinii* either by clinical or microscopical examination. The fungi can only be differentiated by cultures. As is the rule with the *lanosum* variety of ringworm, several of Cornay's patients showed concurrent lesions of the skin. Sometimes there was slight reaction round the lesions on the scalp, this is not seen in ordinary ringworm. The patches were also slightly raised. All the cases were successfully treated by x-rays.

335. Intravenous Injection of Tartar Emetic.

BENJAMINS (*Nederl. Tydschr. v. Geneesl.*, January 1st 1921) states that good results have been obtained by this method in pine diseases—namely, trypanosomiasis, leishmaniasis, granuloma venereum, bilharziasis, diacanthiasis, filariasis, blastomycosis, distomiasis, and chronic malaria. He considers that the treatment deserves a trial in other diseases, especially helminthiasis, diseases allied to blastomycosis—such as actinomycosis—or to trypanosomiasis and leishmaniasis—such as pyroplasmosis. Most writers recom-

mend a sterile 1 per cent. solution. Sterilization can be carried out by a Berkefeld or Chamberland filter. According to De Langen stronger solutions, up to 5 per cent., can be employed, the advantage of which is that a smaller quantity can be injected. The injections are given every other day. The first day 2½ c.cm. are given, containing 25 mg. of the salt, two days later 4 c.cm., then 5 c.cm., and finally 10 c.cm. After an interval of two months a second series is given. A third series is seldom required. Benjamins maintains that this method of treatment, which plays a considerable part in tropical medicine, deserves a wider popularity.

336. Lethargic Encephalitis in the Bordeaux Region.

CROCHET (*Gaz. hebdom. Sci. Méd. de Bordeaux*, January 16th, 1921), as the result of an inquiry into the prevalence of lethargic encephalitis in the Bordeaux region, has collected 145 cases which occurred between March, 1918, and October, 1920. Their classification was as follows: Meningo-encephalitic form, 56 cases; pontine and bulbo-pontine forms, 32 cases; choreic and myoclonic forms, 15 cases; mental forms, 14 cases; epileptic form, 2 cases; hemiplegic form, 2 cases; cerebellar form, 1 case; spinal form, 6 cases; polyneuritic form, 3 cases; unclassified, 14 cases. Of the 145 cases 27 died—a mortality of 18.6 per cent., which was considerably below the figures of 35 and 50 per cent. reported previously. But although recovery was frequent it was far from being always complete, convalescence was extremely slow and sequelae persisted for a considerable time. Mentally the patients remained depressed and incapable of sustained intellectual effort for a long period, and many had to be sent to asylums. A generalized spastic condition of the type of paralytic agitans was very frequent. The prognosis of the myoclonic form was usually grave, of 12 cases, 7 died and 4 were in a desperate condition. No cases of contagion were observed. There was nothing found to justify the conclusion that there was any relationship between lethargic encephalitis and influenza or between lethargic encephalitis and acute poliomyelitis. Lethargic encephalitis was observed in both sexes, in childhood and adult life. Cases were rare after 40.

337. Methyl Alcohol Poisoning

HASKELL, HILLMAN, and GARDNER (*ibid.* Int. M., January 15th 1921) discuss the significance of the acidosis of methyl alcohol poisoning, and the favourable results of treatment with sodium bicarbonate. In experimental animals the severity of the intoxication was at times entirely at variance with the degree of acidosis and it was found that the intravenous administration of an alkali was dangerous, especially if done rapidly, and even when administered slowly vomiting, purging, and convulsions occurred in some of the dogs. While in methyl alcohol poisoning there is a reduction of the reserve alkali of the blood this is not always commensurate with the severity of the symptoms. Although the rapid method of administration to the dogs is not likely to be adopted on human beings, the results serve as a warning against the too ready use of intravenous injections of hypertonic solutions of sodium bicarbonate. Alkaline therapy in methyl alcohol poisoning is not encouraging, and a similar want of success has followed the employment of sodium bicarbonate in the treatment of delayed chloroform poisoning.

338. Hyperthermia as a Symptom of Demorphinization.

BOLTEV (*Nederl. Tydschr. v. Geneesl.*, November 20th, 1920) records the case of a man, aged 26, whose doctor prescribed injections of 10 mg. of morphine and ½ mg. of adrenalin daily for asthma, from which the patient had suffered from early childhood. He gradually increased the dose of morphine until after three months he was taking 100 mg. a day, he was then ordered to discontinue its use. Troublesome cramps in the calves developed, but colic and diarrhoea were only slight, and symptoms of collapse were not observed. On the other hand, the temperature rose several times a day to 104° and sometimes to 105.8°. In spite of the high temperature he did not appear to be ill and the pulse was only 60. The possibility of pyogenic or malarial infection was excluded by examination of the blood, which was always negative. Bolteb attributes the hyperthermia to the fact that

morphine exercised an inhibitory influence on the heat-regulating centres, and that during demorphinization violent irritation of the heat-regulating and vasomotor centres occurred, so that production of heat considerably exceeded its loss.

319. Sodium Citrate Treatment of Thrombo-angitis Obliterans.

ACCORDING to the technique that STEEL (*Journ. Amer. Med. Assoc.*, February 12th, 1921) followed, during the first month the patient is kept in bed with the legs constantly under a hot-air electric-light bath at 110° F., and 250 c.cm. of 2 per cent. sodium citrate solution is given intravenously every second day. During the second month the interval of injection is lengthened to every third or fourth day; daily leg massage is given, and the patient is put in a wheel chair with the feet hanging down for a short time each day; or, if the disease is not advanced, some walking is allowed. The intervals of injection are gradually lengthened until at the end of a year the patient receives one every two weeks. Increased walking is permitted as the symptoms subside and evidence of a functional collateral circulation appear. Potassium iodide, in ten-drop doses, three times daily, is given during the whole course of treatment. The iodide is always well borne. The length of treatment is regulated by the results obtained in establishing a functional collateral circulation. Six patients have been treated. Two have resumed their regular occupations. One was walking around again functionally able, but had no financial spur to set him to work. One who previously had had his leg amputated had resumed his occupation as a playwright. One patient was progressing satisfactorily. In the sixth case—a desperate one—the patient walked after one year of treatment, but suffered a relapse after four months of walking. He was now improving under a second course of injections.

350. The Diagnosis of Hydatid Disease.

LURIDIANA (*Il Policlinico*, Sez. Prat., January 10th, 1921), as the result of his investigation of ten cases, comes to the following conclusions: (1) The most trustworthy biological diagnosis of hydatid disease are deviation of the complement and the intradermo reaction, but neither of them is constantly positive. (2) The two methods may supplement each other; in Luridiana's cases where one was negative the other was positive. (3) The intradermo reaction may be negative (a) owing to interference with absorption of antigen due to causes inherent in the cyst wall, (b) owing to disappearance of antigen from suppuration of the cyst, (c) from excessive absorption of antigen due to antianaphylaxis.

Telangiectasis.

351. GOLDSTEIN (*Arch. Int. Med.*, January 15th, 1921) reviews the literature of hereditary haemorrhagic telangiectasis with recurring (familial) hereditary epistaxis, and reports eleven cases in one family. Telangiectasis is a dilatation of capillaries or venules, and the hereditary type occurs in three forms—pin-point, spider form, and nodular. The lesions are generally confined to the skin of the face and the mucous membranes of the mouth and nose, but they may also involve other parts of the body, and the tendency to recurring nasal haemorrhage (familial in type) is a prominent feature, together with a hereditary history of recurring haemorrhages and telangiectases in the family. The clotting and bleeding time is normal and there is no history of haemophilia in these cases. Fifteen-grain doses of calcium chloride, three times a day, appear to be of some use, though treatment does not afford much relief from the haemorrhages. Mental defect is effective owing to the treatment. Local treatment may reduce the number and severity of the haemorrhages and improve the general condition, and since the bleeding tends to become worse after the fourth decade it is important to try to stop the attacks of epistaxis, especially in women reaching the climacteric. In the case recorded with severe recurring nasal haemorrhages two sisters, seven children, and the patient's mother, all suffered from the same disease. Males and females are equally affected and are equally capable of transmitting the disease to their offspring, and haemorrhage is the one constant symptom, and the source of the secondary anaemia and all other symptoms.

352. Haemoptysis and the Action of Camphor.

ZEHNER (*Zeit. f. Tuberk.*, August, 1920) finds that camphor used as 20 per cent. oil of camphor acts in a mechanical manner, its fermentative, serological, and other effects being secondary. He considers it indispensable in every form of haemoptysis.

SURGERY.

353. Ulcer of Jejunum following Gastro-enterostomy.

ULCER of the jejunum following gastro-enterostomy is stated by HORSLEY (*Journ. Amer. Med. Assoc.*, February 5th, 1921) to be caused by gastro-enterostomy. The manner in which it produces the ulcer has been the subject of considerable discussion. A jejunal ulcer is rarely found except after gastro-enterostomy, though sometimes it occurs after diseases that destroy the efficiency of the pyloric portion of the stomach or that interfere with the normal character of the gastric or duodenal secretion. Horsley reviews the literature, especially with reference to the etiology of the condition. He suggests that the probable explanation is that the changed physiology in the jejunum caused by the gastro-enterostomy weakens the resistance of its tissues, and that traumas or non-absorbable sutures that are easily taken care of elsewhere cannot be borne here. A jejunal ulcer often occurs around the margin of the gastro-enterostomy opening. This probably is because the mucosa of the jejunum nearest this opening is least protected from the effects of the gastric juice. Its resistance therefore is lower, and the trauma or the suturing, particularly if there are non-absorbable sutures, causes the ulcer. The ulceration may occur, however, where the current of gastric juice strikes the wall of the jejunum opposite the stoma. In such ulcers in a region where the blood supply of the jejunum is unimpaired in any way, Horsley says it seems that no other interpretation can be put on the cause of the ulcer than that it is due to the effect of the gastric juice. One such case was described in detail; the patient had a posterior gastro-enterostomy performed for duodenal ulcer, but a jejunal ulcer developed later, and altogether four operations were performed before the patient made a satisfactory recovery.

Treatment of Fractures.

354. ORR (*Journ. of Orthop. Surg.*, January, 1921), from military hospital experience during the war, concludes that the Thomas splint and plaster-of-Paris are the two most important agencies in the treatment of fractures of the femur and leg. The less the Thomas splint is modified, the more efficient it is. In fractures of the neck of the femur and of the leg below the knee, either open or closed, plaster-of-Paris is usually indicated, but for fractures of the shaft of the femur the Thomas traction splint is far more useful, both as an emergency and as a continuous splint, than all other devices recommended, and skeletal traction for fracture at the extreme lower end of the femur or leg is a justifiable addition. In extensive compound injuries of the thigh the Balkan frame, and in a few instances the Hodggen splint, may be serviceable. Moleskin plaster or adhesive glue must be used for traction, which is assisted by elevation of the foot of the bed with the splint anchored at the lower end. The more general adoption of the Thomas splint, and the elimination of most other methods, would tend towards rapid improvement in treatment and results in fracture of the thigh and leg. Complete immobilization of a fracture is rare, and stiffness, excess callus, adhesions, and ankylosis are mainly due to failure to adequately immobilize.

355. Traumatic Serous Meningitis in Childhood.

LINDBERG (*Hygiea*, January 16th, 1921) suggests that though little has been published with regard to traumatic serous meningitis in childhood, this condition is far from rare. Where lumbar puncture to be practised whenever a blow on the head is followed by signs of meningitis, serous meningitis with increased intraspinal pressure would often be found. He records two cases, the ages of the patients being 10 and 4 years respectively. In both a slight injury to the head, caused by a fall on the ground, was followed in a few days by alarming signs of meningitis. In both the pressure of the cerebro-spinal fluid was much raised, being as high as 300 mm. in the second case. The withdrawal of 15 and 20 c.cm. respectively of this fluid, the composition of which was normal, resulted in dramatically rapid improvement, and complete recovery was ultimately effected in both cases. The author advocates lumbar puncture in every case with signs of meningitis; however sure the physician may be that the condition is due to tuberculous or septic meningitis, he may be wrong. And even if a serous meningitis is due to the activities of the tubercle bacillus, it should not be regarded as incurable. The author has seen a case of serous tuberculous meningitis terminating in recovery, and he refers to four similar cases, observed in Göppert's hospital. It is still doubtful what the

fate of patients suffering from traumatic serous meningitis is in the absence of relief of pressure by lumbar puncture; but it is certain that this procedure is remarkably beneficial.

356 Transplantation of the Testes in Man

LICHTEHSTERN (*Zentralbl. f. Chir.*, January 8th, 1921) has performed this operation in 18 cases, in 15 of which testes in the inguinal canal were transplanted, and in 3 cases normal testes. In one case the patient had lost his testes eight years previously, and yet sexual signs returned. One homosexual lost all his signs of homosexuality after transplantation, and 7 other cases showed considerable improvement. A favourable result was also observed in cases of eunuchoidism, consisting of 6 cases of loss of the sexual glands before puberty, 3 cases of acquired and 4 of congenital eunuchoidism.

357 Echinococcus Disease of the Lung and Pneumothorax Treatment

ACCORDING to ALEXANDER (*Zentralbl. f. inn. Med.*, November 15th, 1920), who records an illustrative case, artificial pneumothorax is contraindicated in pulmonary echinococcus disease which is not definitely connected with a bronchus, owing to the danger of rupture of the cyst into the pleural cavity. On the other hand, if there is a definite connexion with a bronchus, pneumothorax treatment can be employed, but much increase of pressure should be avoided. Pneumothorax treatment is a good preparation for the radical operation, and should be continued after the operation, so as to promote a more rapid healing of the wound cavity.

358 The Use of Propyl Alcohol in Surgery.

PLETH (*Il Polichimico*, Sez. Prat., January 10th, 1921), who has used various colouring matters, such as malachite green, brilliant green, and fuchsine, in the treatment of wounds for several years, has recently been in the habit of suspending the colouring matter in a solution of 25 per cent propyl alcohol. He has come to the conclusion, from observation of several hundred cases, that infected wounds, when treated with propyl alcohol or with colouring matter dissolved in propyl alcohol, are cured more rapidly than by the Carrel Dakin method. He has used this treatment with success in skin diseases, such as blastomycosis and actinomycosis, and has obtained good results in disinfection of silk ligatures in 25 to 50 per cent. propyl alcohol with or without the addition of an amiline dye.

359. Ludwig's Angina in a Haemophilic Subject

FELICIANI (*Il Polichimico*, Sez. Prat., January 3rd, 1921) records the case of a man who an hour after an operation for Ludwig's angina developed profuse and persistent haemorrhage from the wounds in the neck. Ligot, adrenalin, gelatine, peptone and diphtheria antitoxins proved ineffective, and it was not until the seventh day after the operation that some fresh horse serum was obtained, and 200 c cm were injected. A surprisingly good result was obtained, there being a marked decrease in the haemorrhage. During the next six days 120 to 200 c cm. of the serum were injected daily, and recovery took place.

360. Meningococcal Arthritis

VERLE (*These de Paris*, 1920) discusses the different forms of arthritis which occur in the course of cerebro spinal meningitis. Usually these take a purulent form, have a decided predilection for the knee, and are relatively indolent. Sometimes the joint affection precedes the meningitis and may be mistaken for rheumatism. In this case the onset of cerebral symptoms may lead the clinician to think of cerebral rheumatism. Diagnosis is of course easily made by exploratory puncture of the joint. Usually the arthritis will clear up under serum treatment of the usual type, but if the joint trouble persists, aspiration of the pus and intra articular injection of antimeningococcus serum may be tried. Only in the most resistant cases should the joint be opened and drained, although this step does not always lead to ankylosis.

361. Traumatic Optic Atrophy.

GIVESTOS and DEBÉDAT (*Journ. de Méd. de Bordeaux*, November, 1920) report a case of monocular blindness following trauma. A boy hit his right frontal region violently against a tree. He immediately lost consciousness, and had epistaxis. Radiographs revealed no fracture of the skull. Vision in the right eye was completely abolished, the disc becoming white and atrophic. The authors surmise a perineural haemorrhage leading to atrophy of the optic nerve.

OBSTETRICS AND GYNAECOLOGY.

362. Treatment of Placenta Praevia.

THILLIN discusses (*Rev. med. de la Suisse rom.*, February, 1921) at length the value of the following methods of treatment of placenta praevia: (1) Accouchement forcé, (2) rupture of the membranes, (3) plugging of the vagina, (4) bipolar version and tension on the leg of the child, (5) Pressure by means of a hydrostatic bag, such as Chassapetier de Ribes's, and (6) Caesarean section. Accouchement forcé, he states, has been abandoned because of the risk of severe lacerations of the cervix. Rupture of the membranes, he considers, is only useful in those cases where there is a partial placenta praevia. Plugging of the vagina is useful in cases where labour has only just commenced, and the cervix is not dilated. The method of Braxton Hicks—that is, bipolar version—has become a classic because of its great success, and has reduced the maternal mortality considerably. It has, however, one great disadvantage—namely, the large foetal mortality. All the methods so far mentioned require no very great experience or skill on the part of the operator, but they are all attended by a very high foetal mortality. The one method by which this high mortality can be overcome is Caesarean section, and he compares the results obtained by some obstetricians—namely, 100 per cent of mothers and children living—with the results by other methods, which average a foetal mortality of 53 per cent, and a maternal mortality of 9.3 per cent. He points out a number of contraindications to Caesarean section, the most important of which is the suspicion of sepsis in the vagina or cervix. The diagnosis of a dead child also should contraindicate this method. In conclusion the author gives in detail six cases of placenta praevia which he himself treated by Caesarean section; in every case the mother survived, and likewise the child, with one exception where the child was dead at the commencement of the operation.

363 Is it Necessary to Treat the Pregnant Wife of a Syphilitic?

CARLE (*Ann. de Derm. et Syph.*, No. 1, 1921) discusses this subject and definitely concludes that the wife of a syphilitic is only to be treated if she shows signs, clinically or by blood test, of the disease. Conceptional syphilis, he says, does not exist, and if the encephalic woman develops syphilis it is not contracted through the child or placenta. The old habit of giving mercury and iodide to the pregnant wife of a syphilitic husband is bad and even harmful. Should the encephalic woman have clinical or laboratory evidence of syphilis, then she must be treated by the modern intensive method. Carle holds that the encephalic woman should not be told of the taint in her husband as she is liable to develop neurasthenia or syphilophobia. It may be, and often is, necessary to obtain the help of the family physician to carry out the complete examination and to obtain the blood for the blood test.

364 Coloured Colostrum

REICHENFELD (*Wien. klin. Woch.*, January 6th, 1921) states that, while discoloration of the mammary secretion by blood, haemoglobin, or its derivatives is by no means uncommon, very few cases have been described of non-haematogenous discoloration of the colostrum. He records a case of a woman, aged 34, suffering from endometritis and inflammation of the adnexa, probably due to abortion, who presented a thick, first dark green and then light green, secretion from the nipples, especially the left. She stated that she had suckled her child, who had been born two years previously, when the milk had a normal appearance. Microscopical examination of the secretion showed relatively few colostrum corpuscles, and mainly fat droplets. Bacteriological examination was negative. Inoculation of normal colostrum and cow's milk with the green secretion did not produce any change in these fluids. The green secretion lasted for the three months that the patient was kept under observation, and was always more plentiful from the left than from the right breast. The urine, sweat, and saliva showed no abnormal coloration. The Wassermann reaction was negative, and there was no evidence of syphilis.

365. Primary Carcinoma of the Vagina

KLERNANN (*Monats f. Geburtsh. u. Gynäk.*, 11, 4) records a case of this rare condition, accidentally discovered in a woman, aged 75, who suffered from prostatica. Total extirpation was performed. The tumour was a squamous-celled carcinoma and the cervix was normal.

366. Morbid Anatomy of Lethargic Encephalitis.

ANGLADE (*Gaz. hebdom. des Sci. Méd. de Bordeaux*, January 16th, 1921) states that all the cases examined by him presented the following characteristics: (1) The cerebral cortex in the frontal region was always the site of a process of encephalitis. The large and moderate sized nerve cells presented various degrees of chromatolysis. (2) The grey substance of the cord showed changes similar to those observed in the brain. (3) The lesions were diffuse both in the brain and cord. Anglade regards epidemic encephalitis as the result of a general infection of the nervous system. Histologically this infection is manifested (1) by inflammatory lesions disseminated throughout the cerebro-spinal axis, (2) by focal lesions situated round vascular terminations. The mesencephalon, grey substance at the base or centre of the brain, and the locus niger appear to be the sites of predilection for the formation of these foci.

367. Failure of Antibody Formation in Leukaemia.

KATHERINE HOWELL (*Arch. Int. Med.*, December 15th, 1920) inoculated two patients—one suffering from lymphatic leukaemia and the other from myelogenic leukaemia—with 0.5 c.cm. of triple vaccine (1,000 million *B. typhosus*, 750 million *B. paratyphosus* A, and 750 million *B. paratyphosus* B per cubic centimetre). The blood count and the opsonin and agglutinin for each bacterial species were examined before inoculation and at intervals thereafter. In the case of the lymphatic leukaemia there was no rise of temperature, haemoglobin, or other toxic reactions. At no time did even undiluted serum show the presence of agglutinin or opsonin. A control healthy case gave general reactions, and antibodies were present in high serum dilutions after the twelfth day. In the case of myelogenic leukaemia the only symptom noted was a rise in temperature of one degree. Undiluted serum from this patient agglutinated *B. paratyphosus* A and B very slightly, but never clumped *B. typhosus*, whilst the opsonin was never above normal. A healthy control showed rise in temperature and general malaise, and his serum gave agglutinin after the tenth day. The observations of other authors on spontaneously infected cases or on those infected with other organisms seem to bear out the contention that the tissues of a leukaemic individual have lost the property of antibody formation in general. The loss of ability to form antibodies is probably the result of the marked alterations in the haemopoietic tissues which characterize leukaemia. This loss of ability may be due to the excessive proliferation of these tissues, one of whose normal functions is the formation of antibodies. With rapidly repeated cell generations the cellular energy used in multiplication prevents the utilization of the energy which is necessary for normal function.

368. A New Method Facilitating Detection of Tubercle Bacilli.

GRYZEZ and BERNARD (*C. R. Soc. Biologie*, December 4th, 1920) describe a new method of treating sputum, pus, faeces, etc., in which it is desired to determine the presence of tubercle bacilli. To the suspected fluid (10 volumes) is added filtered sterilized ox bile (8 volumes), to which two drops of tincture of iodine have been added per cubic centimetre. The mixture is shaken and becomes completely liquefied after eighteen hours at 37°C., three hours at 56°C., or fifteen minutes at 100°C. After cooling, one-third the volume of saturated salt solution is added, then 2 or 3 c.cm. of ether. After shaking the mixture is centrifuged (about 6,000 revolutions). By means of a platinum loop fragments are withdrawn from the pellicle which forms at the junction of the watery and ethereal layers. Using this method the authors have found among 73 sputa 23 instances in which a positive result was found in cases which by the ordinary methods appeared negative; tubercle bacilli were found also in 4 cases of cold abscess and 3 of pleuritic effusion.

369. Rate of Sedimentation of the Blood Cells in Tuberculosis.

WESTERGREN (*Acta Medica Scandinavica*, January 26th, 1921) reports favourably on a simple test, the principle of which depends on the fact that the rate at which the blood cells sink in a vertical column of blood is hastened by various diseases, including tuberculosis. He describes in detail the technique of this test, and discusses the results of about 3,000 tests made on 500 persons, 369 of whom were tuberculous. The rate of sedimentation varied greatly in health and disease; it ranged from 1 to 120 mm. per hour; but a rate that exceeded 10 mm. per

hour was invariably associated with some pathological condition. The author found this test of little diagnostic value because in pregnancy and in a host of diseases other than tuberculosis the rate of sedimentation is affected. On the other hand, he found it of great value in gauging the degree of activity of the tuberculosis, for the rate of sedimentation varied directly with the activity of the disease, as determined by clinical examination. Interesting observations were also made as to the rate of sedimentation as determined by injections of tuberculin. The test was more delicate than the measurement of the temperature as an index to the degree of activity of the disease; in some cases the rate of sedimentation began to rise some time before a rise of temperature was demonstrable by the thermometer. The author suggests that this test may indicate a condition which he describes as "fever without rise of temperature." The test was not only of great prognostic importance, but also a valuable guide to the effect of treatment on the course of the disease.

370. Influences on the Metabolism of Bacteria.

The effect of moderate concentrations of disodium hydrogen phosphate (2 per cent.) on the growth of *B. coli*, *Vibrio septique*, *B. welchii*, *B. sporogenes*, and *B. histolyticus* in glucose peptone has been investigated, and the effect of acid potassium phthalate and sodium pyrophosphate on the growth of *B. coli* ascertained by WOLF (*Brit. Journ. Exper. Pathol.*, December, 1920). In all cases the buffer salt either partially inhibits gas production or produces a lag. If the fermentation be very prolonged, the volume of gas may finally approach that obtained from a non-buffered medium. The effect of phosphates on gas production is most pronounced in the case of actively saccharolytic organisms, but is also definite with proteolytic bacteria such as *B. sporogenes* and *B. histolyticus*. The effect of phosphates on the nitrogen metabolism is not pronounced. On the whole the formation of amino-acids and ammonia from a medium containing peptones, polypeptides, and amino acids is not increased. In the case of the saccharolytic organisms the acid production appears to be increased when buffer salts are added to the medium. This bears out some of the results which have been obtained with similar organisms when fermentation takes place in the presence of calcium carbonate. The final reaction of the fermentations is affected by the presence of buffer salts in the sense that in no case does the medium become so acid in the presence of buffer salts as it does when these salts are absent. The toxin formation in *Vibrio septique* cultures is influenced by the presence of a buffer salt—sodium phosphate. The toxin has a higher potency than the control made without the salt. It is shown that toxins may be kept potent for long periods of time in the presence of sodium phosphate under conditions which would quickly destroy the toxicity of a product made in an unbuffered medium.

371. Cholesterol in Xanthoma Multiplex.

BURNS (*Arch. Derm. and Syph.*, October, 1920) agrees with the more recent histologists in regarding the tumour like nodules of this disease to be a dermatosis originating in the excessive amounts of cholesterol in the blood, the substance being deposited in the skin, where it induces a secondary connective tissue hyperplasia. Histologically a xanthoma nodule is composed of fibroblasts forming a loose network, within which are large vacuolated cells containing apparently a fatty material. There are many needle-like spaces between the fibrils, which have probably contained cholesterol crystals. About these spaces may be found clusters of foreign body giant cells. On chemical examination large quantities of cholesterol are found. In Burns's case the blood was examined for cholesterol, which was found to be considerably increased under normal mixed diet, under low fat diet, and under high fat diet. Under high fat diet the increase was excessive. It is possible that the occurrence of xanthoma diabetorum is due not to the presence of sugar but to the associated cholesterinaemia.

372. Preparation of Serum on a Large Scale.

SORDELLI (*Rev. del Inst. Bact.*, December, 1920) describes the following method of obtaining horse serum on a large scale. The blood is collected in a sterile 2.5 per cent. solution of sodium oxalate in distilled water. After forty-eight hours the plasma is withdrawn and coagulated by adding 1.2 to 1.4 gram calcium chloride to every 1,000 c.cm. of plasma, and the serum is then rapidly strained through a filter. Large quantities can thus be rapidly obtained of a uniform serum which is less likely to give rise to serum disease.

Advances in Treatment.

Rational Urinary Antisepsis

THE action of hexamethylenetetramine as a urinary antiseptic is dependent upon its conversion into formaldehyde in the urine. This conversion is a simple chemical process which occurs in acid but not in alkaline media: it obtains only in the presence of true acidity and is proportionate to the hydrogen ion concentration.

"Cystazol"

(Regd. Trade Mark)

is a combination of hexamethylenetetramine with sodium benzoate. The benzoate moiety raises the acidity of the urine and thus insures the liberation of formaldehyde. During treatment with "Cystazol" the use of alkali acetates, citrates, tartrates, etc., should be discontinued, as these render the urine alkaline and thus destroy the efficiency of the hexamethylenetetramine.

"Cystazol" is employed in Cystitis, Gonorrhœa, Bacillus Coli Infections and Bacilluria of all types. It is recommended to be given in Typhoid Fever to prevent spread of infection; it should also be used for Typhoid Carriers as long as the bacilli are present in the urine.

Dose:

One to three tablets, with water, twice or three times daily.

"Cystazol" is supplied in bottles of 20, 40, 80 and 160 (10 grain) tablets.

Retail Prices:

1/6, 2/6, 4/6 and 8/6 each.

Unsolicited Testimony.

A Doctor of Medicine writes:

"I am greatly obliged to you for sending me a sample of 'Cystazol,' which I have found to be the best urinary antiseptic I have yet tried; I have been infected with Bacillus Coli for about a year and nothing has removed the offensive odour of the urine so effectually."

Increase in Use of Glaxo Decline in Infant Mortality

Many factors have combined to bring about the remarkable decline in infant mortality during recent years, but there must be few who will not now concede that the replacement of far-inacious foods and infective raw milk by properly prepared standardised dried milk has been a factor of some importance in this work. This chart shows the increase in the amount of Glaxo consumed during recent years in comparison with the annual infant mortality rate over the same period.

THE IMPORTANCE OF THE INFINITELY LITTLE.

BEING THE MACKENZIE DAVIDSON MEMORIAL LECTURE.*

BY

W. D. HALLIBURTON, M.D., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN KING'S COLLEGE, LONDON.

IN 1798 there died in Bologna one who was born and lived there. His name, which has reverberated down the ages, was Aloysius Galvani. Destined for the Church of Rome, but later expelled from that body, he happily turned to science, and became Professor of Anatomy and Physiology at the University of his native city in 1762. The story of his well-known discovery of what was later called galvanism is well known, and does not need recapitulation here. Helmholtz, writing nearly a hundred years later in an appreciation of Galvani's pioneer work, said:

"When Galvani touched the muscles of a frog with different metals and observed their contraction, who could have dreamt that all Europe would be traversed with wires flashing intelligence from Madrid to St. Petersburg with the speed of lightning? In the hand of Galvani, and *first even in Volta's, electrical currents were phenomena capable of exciting only the feeblest force, and could not be detected except by the most delicate apparatus. Had they been neglected on the ground that the investigation of them promised no immediate results, we should now be ignorant of the most important and most interesting of the forces of nature.*"

Had Helmholtz been alive to-day, how greatly might he have expanded this theme; for even he did not foresee the possibilities of electricity and its ramification into every branch of our daily life, including its applications for the detection and alleviation of many of our ills. Animal electricity in its medical aspect is, it is true, as old as galvanism itself. In its early days thinkers imagined the secret of life had been found, and attempts were made to convert dead into living bodies by its means. It soon lent itself to the worst forms of charlatanism and quackery. But as knowledge progressed and ignorance was dispelled, it found its proper sphere, and the importance of the sphere is evidenced by the existence in our Royal Society of Medicine of a Section devoted to electro-therapeutics.

To trace even in outline the various steps which have led to the present proud position in which this branch of science stands to-day would be a task beyond my powers and beyond your powers of endurance, but I may take as my text to illustrate one feature in the advance (if not its mainspring) a reminiscence of my own.

In 1888 I attended at Bath a meeting of the British Association, and as it was almost the first I had been to I listened to the Presidential and other addresses with great attention and with becoming reverence. The President that year was the great engineer, the late Sir Frederick Bramwell, and well do I remember how he started his address. He began by alluding to a speech he had heard from the late Lord Iddesleigh, who charmed an audience for a whole evening by speaking on the very important subject, "Nothing." Sir Frederick said he would not try to copy this feat, but would do his best to speak on "Next to Nothing." By this neat phrase he meant those little things which are of supreme importance. He gave numerous examples from his own subject to show how it was that attention to details had converted crude machinery into effective and useful instruments, whether they were guns or bridges, engines or ships. Among other subjects he took to illustrate his theme I remember he singled out the telephone as a triumph of science which the "next to nothings" had done so much to perfect. At that time he was naturally not aware of how in later years red-tapeism (and the like) would have taken upon itself to neutralize some of the excellent qualities that science had bestowed upon it. At the conclusion he ventured to prophesy that it would not be long before men were able to fly.

But gifted as Sir Frederick Bramwell was with the prophetic instinct, he did not at that time, now thirty-three years ago, foretell the discovery of those vibrations

which it is now customary to term x rays, nor of these other kinds of radiant energy which the name of radium calls up. Still less could he have predicted the value of these discoveries to medicine and to surgery, and least of all would he have pictured even in imagination the coming of a man who so fully illustrated the importance of attention to details, to the "next to nothings," a personality whose name we are met together to commemorate this evening. Sir James Mackenzie Davidson, whose sterling and genial character we all remember with affection, was first and foremost one who never spared trouble; he was one whose numerous inventions, the result of his painstaking attention to apparently small and trivial things, succeeded in making the bare bones of his subject live, just as his skiagrams represented them in life-like perspective.

I wish that your Section could have selected someone more capable than myself of dealing with this subject from the technical point of view. But you could not have chosen one who has a greater admiration for the genius and ability of our lamented friend. Your choice has fallen on a physiologist whose labours have been more directed into chemical than physical channels, and I regard it not so much as a compliment to myself, as an honour to our band of quiet workers who are seeking out the ways of Nature by the way of experiment, and are doing their best to give to the art of medicine the sound basis of scientific knowledge. For too long the workers in the laboratory, and those by the bedside, have been groping out their own salvation in separate ways. Your request that a physiologist should address you to night is evidence that the *entente* between us which is now happily growing needs still further strengthening.

I feel, also, that it does us all good to get at times out of our own special ruts. I feel this evening renewed vigour as I come into the fresh air of electro-therapeutics; I can only trust the members of your Section may be able to return the compliment, and find something useful or even instructive in what I have still to say, even although it deals in the main with another corner of medical science than that they are accustomed to live in.

I am not here only to utter sentiments however heartfelt, or platitudes however true, still, before coming to what after all is my main subject, there is one general consideration which I should like to place before you.

The crowded condition of the medical curriculum, in which the poor unfortunate student is presented with an ever-growing number of subjects for study while the length of the day still remains at the usual standard of twenty-four hours, is producing just now one of those attempts which recur periodically to revise his scheme of study. We are told that there is no need for him to learn his anatomy so thoroughly, that his organic chemistry must be reduced to a minimum; and, last and worst, his physiology course must be drastically shortened, and this in spite of the fact that all these subjects are growing fast, and that medical men are seeing more and more the truth that physiology is the corner stone around which the superstructure of medical science is built. Although physiology still figures on paper as quantitatively large, the restriction suggested is in the kind of physiology to be taught, and the term applied physiology designates that what is wanted for the student is physiology in its direct bearing on medical practice. The frog, which has served for so long as the object lesson of so many physiological lessons, is to be deposed from its high position, and, so far as is possible, experiments on man himself are to be substituted.

In speaking of Galvani's work, I have already given one example of how a subject of purely scientific interest, studied with no ulterior or utilitarian motive, was found to be of inestimable value to mankind. Such instances could be multiplied indefinitely. How would Lister's work have been possible without the preliminary academic labours of the chemist Pasteur? When Miescher set out to investigate the chemistry of the roe of the salmon, did he think that it would be on that investigation that our knowledge of the pathology of gout would be founded? When Bayliss applied himself to study colloids, he could not have dreamed that a powerful weapon against wound shock would be discovered in that by-path. But I need not weary you with other instances. When a scientific man studies Nature for the sake of pure knowledge, who can say to what practical use his followers may adapt it?

* Delivered before the Section of Electro-Therapeutics of the Royal Society of Medicine.

In deciding in my own mind whether I approve or disapprove of these attempts to reform or revolutionize medical training, I am torn by conflicting emotions. On the one hand, I sympathize deeply with the student, and realize the impossibility of getting a quart into a pint jug; on the other hand, there is my love of pure science, and the conviction that any and every truth must ultimately bear practical fruit. I am not conservative by nature, and welcome every true reform, and I have little sympathy with the legendary professor at one of our ancient seats of learning who, at the end of a life devoted to laborious research, thanked God he had never done anything that would be of the slightest use to anyone. One has in such an impasse to face facts and exercise one's common sense. A thorough grounding in general physiological knowledge must remain a *sine qua non*, but in the details of its many ramifications one must make a judicious selection, and the choice must naturally first fall on those parts of the subject in which the practical outcome is already realized rather than on those the application of which is still to seek. From the point of view of those in this Section, and of those who aspire to join its ranks later, one trusts that the electrical phenomena which are so easily demonstrated in all essentials on the muscles and nerves of frogs will not fall under the ban of those who are trying to limit the excursions of the student into the scientific aspects of the subject.

In speaking further, I thought the occasion might not be inopportune to say a few words on some of the modern problems of physiology, and tell you briefly of some of the progress we have made and are making at the present time. To attack all these questions in the space of a single address would be impossible. Again, one has to make a selection, and I intend to limit myself to three. I think it will be found that in these three cases the importance of the "next to nothing" principle will be abundantly illustrated. This is the day of great things, because we are realizing the importance of the infinitely little.

The invention of the word hormone dates from the discovery made by Bayliss and Starling of the chemical messenger which is elaborated in the intestine under the influence of the gastric acid, and which, after absorption, stimulates the pancreas to pour out its juice at the time when it is wanted to carry on to completion the digestive work begun in the mouth and stomach. Previous to this time we were imbued with the teaching that the harmonizing or, to use Sherrington's phrase, the integration of the bodily functions is due to the activity of that ruling system of the body known as the "nervous system." The nervous system is not displaced from its high estate, but for the first time in the history of our science we realized to the full the valuable help rendered to the telegraphic service of the body by humbler but none the less useful ministers to our comfort which Starling aptly compared to the postmen. Although the actual word hormone was not coined until secretin was discovered by Bayliss and Starling, the importance of chemical agents had been really recognized somewhat earlier, and more especially in relation to that group of formerly mysterious organs known then as the ductless glands, but now generally dubbed the endocrine organs; they are so called because they form an internal secretion, that is a secretion which leaves by no specific duct, but by the blood or lymph that streams from the organ in question. It was no wonder that ignorance prevailed for so long as to their function, seeing that the new chemical principle each forms is masked by the protein-rich fluid which it enters. But now, thanks to the overcoming of this and other difficulties, we know a good deal about the thyroid, the adrenal body, the pituitary gland, the islets of Langerhans, the corpus luteum, and others.

Many details have still to be worked out, and some of our ductless glands are territories almost as unknown as Central Africa was in our youthful days. The chemical messengers are all grouped together under the general name hormone, a term which immediately "caught on." Attempts have been made to distinguish classes among the chemical messengers to indicate that some stimulate, some depress, and so forth. But the terms introduced with this object by Sharpey Schafer, and more recently by Gley, have not yet at any rate passed into general usage. Speaking of our French colleague, Professor E. Gley, reminds me that the term "internal secretion" was

first employed by another great Frenchman, Claude Bernard, in relation to the liver's important work in pouring sugar into the blood stream at a steady pace. In most cases the index pointing the way to discovery has been the result of removing the organ and of injecting extracts of it into the blood and noting the results. Professor Gley has recently in one of his published discourses laid down the conditions which must be fulfilled in order that a gland may be admitted to the class of endocrine organs. He very properly decries trust being placed merely upon the results of ablation or the effects of injecting extracts. In addition there are three main conditions which must be conformed to in order that a gland may be enrolled within this category: first, the anatomical, that is, the absence of a duct; secondly, the chemical, the recognition in the venous blood of such organs of a specific chemical product; and thirdly, the physiological, the possession by the venous blood of specific physiological properties, and this last is of course the superlative test. He takes the work of Bayliss and Starling on secretin as an example; it was not until Fleig, and Enriquez, and Hallion actually worked with the venous blood coming from the duodenum that the probability of the truth of Bayliss and Starling's views founded upon the results of injection of duodenal extracts was rendered a certainty.

Professor Gley has done good service not only by his own experimental work, but in pointing out the way in which work on this subject must be continued. For we must confess that up till now our conclusions in reference to many of the endocrine glands do not rest on experiments which fulfil all of Gley's conditions. We must further recognize that it does not follow that because most of these ductless organs form internal secretions, all of them do so. Nature seldom works in one pattern, but her *modus operandi* varies. The parathyroids, for example, probably form no substance useful to the rest of the body's machinery, but probably act by removing or centralizing harmful products formed elsewhere. Noel Paton and his colleagues have shown that the poison they detoxicate is a guanidine compound derived from muscular metabolism, and if this is not removed tetany is the result.

Restricting ourselves, however, to the truly endocrine glands, let us dwell for a moment, not on what we know, but on the gaps in our knowledge. The chemical constitution of that iodine complex which is secreted by the thyroid has been unravelled by Kendall in America. The constitution of adrenaline secreted by the suprarenal medulla is so well recognized that it has even been synthesized by laboratory processes. The composition of pituitrin secreted by the posterior lobe of the pituitary body looks as though it will be the next to yield to the chemist's manipulations. But what do we know of the internal secretion of the part of the pituitary which is probably most essential to life, or of that of the suprarenal cortex, which is certainly the most important portion of that gland, or the nature of the internal secretion of the pancreatic islets, or of the corpus luteum in the ovary, and even of secretin itself? I mention these few hiatuses in our knowledge to illustrate how much our wisdom is in its infancy, what fields are still to be tilled, and lest we swell with undue pride at our present accomplishments. But, whatever gland we think about, we may be sure that quite minute quantities of their various secretions are sufficient to do the necessary work, and that these infinitesimally small amounts are indispensable, not only for our well-being, but for life itself. This, at any rate, has been proven for those secretions which can be quantitatively examined. Even although our knowledge of pituitrin is still over the border, we know that extreme dilutions of pituitary extract can exert marked power in causing plain muscle to contract vigorously, and, in the case of adrenaline, one can demonstrate that the injection of a few cubic centimetres of a solution containing only one part in a million or more of neutral saline diluent will provoke marked physiological effects on heart and blood vessels.

Other examples of organic substances which call forth physiological effects in equally minute or even more attenuated concentrations might be given; there is, for instance, an acetyl derivative of choline, one of the constituents of our body, and the powerful amine known as histamine, which may be mentioned. In anaphylaxis, also, similar infinitesimal amounts of organic substances produce gigantic effects. Such minute doses make the doses of that product of a past generation known as

homoeopaths seem enormous in proportion; a reflection which will awake an echo in the hearts of those who deal with radium emanations.

From the days when we learnt physics, we doubtless remember that important natural law which states that action and reaction are equal and opposite. The law holds in the opposing activities of our hormones, and an important branch of study has been to ascertain how such opposing actions are balanced so that they work together for good. The way in which the different organs, endocrine and otherwise, act and react upon each other has been one of the most instructive and interesting outcomes of the discovery of the internal secretions themselves. I do not think one could find any other subject which has in the present day so deeply influenced medicine as the hormone conception. Instead of remaining, as many physiological discoveries have remained, dormant as praiseworthy laboratory curiosities, the application to the practical study of disease has here been immediate, and medicine, surgery, gynaecology, and the numerous specialities of practice have all been profoundly influenced by the new doctrines. Among the specialities one must here particularly allude to the one represented here this evening. Those who, on the one hand, are employing in diagnosis and treatment various electrical forms of energy, and those who are similarly engaged in radiology, have recognized that they have the power of controlling and influencing the endocrine organs to form more or less of these internal secretions for the benefit of their patients. I wish I had the special knowledge to dwell for a moment on this aspect of the problem, but those who are listening to me will be able to fill in the details of this part of the picture. The discovery of radium has been one of the greatest feats of modern science, but I need not tell my hearers that this new power for good may, like the α rays, be also in unwise hands an equally powerful agent for evil. When the activity of its emanations on living cells were first demonstrated there was perhaps naturally too great confidence displayed in its ability to cure every ill, including those which, like cancer, had defied every previous effort to conquer them. That phase is now passed, and the proper place of radium in our armoury is being adjusted to the facts. History is always repeating itself, and the story of radium is a repetition of what has occurred before when startling new discoveries had been revealed to the world. In the old days of the alchemists, who sought by magic and by the help of astral and similar agencies to discover the philosopher's stone and the elixir of life, the disappointments and failures were as numerous as the attempts to discover the secret of vitality. When alchemy was replaced by more exact science, new revelations were wistfully and hopefully regarded as likely to yield the long-bidden secret; two of these epochs I have already alluded to to-night—one was the discovery of galvanism in the eighteenth century, the other of radium in the twentieth.

May I digress and linger a moment to mention one more which marked a similar epoch in the seventeenth century? I allude to the discovery of phosphorus. In the early years of that century a substance was prepared by heating heavy spar with combustible organic matter (egg white and charcoal) and this substance glowed in the dark, and for many years the name phosphorus, or light-bearer, was given to any substance which had the same property. The actual element we now call phosphorus was prepared by Brand about 1670, and was at first made in small quantities only from animal products—namely, urine and bones. Can it be wondered at, that in those days of superstition and mysticism the discovery in animal products of a substance which burnt and emitted light without ignition was hailed as a discovery which at last had hit upon the vital principle? Phosphorus played an important part in the development of the theory of phlogiston which soon afterwards dominated philosophic thought, but in time died like so many other theories before and since. The *furor* created by the discovery of phosphorus had been paralleled by the discovery of radium in recent years. Only let us congratulate ourselves that the 250 years which intervened between the two events have taught us more wisdom and we are not so likely to repeat the hysterical enthusiasm of our ancestors.

This, however, is a parenthesis which originated from my mention of the fact that hormones and all that they connote are not simply of chemical interest, but that their importance is recognized as a factor in electro-therapeutics as in other branches of medical science. I do not think I can say the same thing about the second subject I have selected to bring before you. My only excuse for so doing is that it is one on which I can venture to speak at first hand. It may not interest you as electro-therapists, though it is not devoid of importance to you as human beings, for to all living creatures the question of food is of superlative value. The particular portion of this wide problem I intend to say a few words about is one in which also the quantitatively little is qualitatively great. I allude to those substances in our diet which we term the vitamins. The word "vitamin" is not as old as the present century, and although it is not an ideal term it has come to stay, and is certainly less cumbersome than the phrase "accessory food factor" which is its synonym.

The lecturer then gave a brief summary of our knowledge of the vitamins, and alluded to the importance of the "next to nothing" principle there. Though accurate quantitative methods are still to be devised for their estimation, one thing is perfectly certain, and that is that the requisite amount is extremely minute, and this small amount is capable of converting a useless into a useful diet. He then continued:

Before I leave the subject of food may I unburden myself of a suggestion? Empiricism is not always to be condemned. What we call empiricism is frequently the result of past experience. As an example, take a prescription of cod-liver oil, or of butter and cream. A few years ago it would have been impossible to explain why these forms of fat are superior, we will say, to olive oil and vegetable margarine. The mere fact that they are better was empirical, and now the practitioner has been fully justified, and research at last has told us the explanation—namely, the existence in the fats, which are the more valuable for remedying malnutrition, of a health-giving vitamin.

May not this in the future be repeated? If you have high blood pressure why does your medical man tell you you may take fish and poultry and eggs, but that you must abstain from beef and mutton? I can picture a sceptical and argumentative physiologist saying, "Why? The materials you mention and I am advised to take or refrain from taking are all in the main composed of protein, and surely it is not physiological to give me such futile advice." My answer to this would be, "True, it is not explicable yet on physiological grounds. It is the mere result of empirical experience. But wait a few years, and it is quite on the cards that by that time science may have stepped in and explained the puzzle, just as a few years ago it was able to explain why cod-liver oil is better than olive oil." There is probably in the harmful meats some hitherto unrecognized principle, unrecognized because it is present in minute quantities; or it may be the absence of an indispensable material. It is one of the "next to nothings," but it makes all the difference. "There is one kind of flesh of men, another flesh of beasts, another of fishes, and another of birds." I wonder if St. Paul ever imagined these pregnant words contained more than what he intended to convey by them.

The third topic the lecturer selected to illustrate the importance of attention to apparently insignificant minutiae was that of the capillary circulation, a subject which rose into importance during the war in relation to "shock." Here, again, especially in some forms of secondary shock where actual haemorrhage may have been insignificant, but where crushed tissues were the usual accompaniment, it seems inevitable to accept the views urged by Dale and others, that it is a toxic condition. The poison is produced from tissue breakdown, and operates by reducing capillary tone, so that the blood is stagnant and side-tracked in the capillary lake. Whether histamine, which certainly produces a shock-like state in this way, is the actual poison in secondary traumatic shock, or the only poison, is a question still to be answered. But, whatever the poison is, it is one of which a very small quantity produces a very large result.

The lecturer concluded as follows: In conclusion, I must thank you for the patience you have exhibited in listening to me for so long. I wish I could have chosen a subject, or subjects, more akin to your own speciality. But if anything I have said in my disjointed remarks will help you to realize how widespread is the importance of the infinitely little my task will not have been in vain.

GLANDULAR FEVER.

BY

H. LETHBY TIDY, M.D.Oxon., F.R.C.P.Lond.,

ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL AND PHYSICIAN
TO THE GREAT NORTHERN HOSPITAL,

AND

E. B. MORLEY, M.B., B.S.Lond.

GLANDULAR FEVER was first described by E. Pfeiffer in 1889 under the title "Drüsenfieber." It may be defined as an acute infectious disease principally of children, characterized by rapid enlargement of the cervical glands and by a less constant enlargement of the liver, spleen, axillary, inguinal and other glands. The disease is rare, but there is some reason to believe that a considerable number of cases are occurring at the present time.

The largest epidemics are those recorded by Park West, 96 cases; Botschkowsky, 54 cases; Byers, 33 cases; Stark, 30 cases; Tschagajew, 24 cases. Korsakoff has reported 29 cases observed over a course of years.

Pfeiffer stated in his original article that the disease occurred in small epidemics, and especially in "house epidemics"; when one child of a family was affected the others rarely escaped. Subsequent observers have agreed that it is infectious. Fisher records 8 cases in one family, and Chapman 5 in his own household. Park West observed an epidemic in a country district in Ohio, and saw 96 cases in the course of three years, besides hearing accounts of at least 40 others. The 96 cases occurred in forty-three families, about 20 children in the affected families not being attacked. He states that the epidemic spread irregularly, the houses attacked not being in any special contiguity or social connexion with each other. Von Starck's 12 cases occurred in eleven families, Haas's 12 cases in ten families, and Schiller's 11 in nine families. Schäffer's 21 cases occurred in the space of four months in an institution for children, but there is no statement as to the total number of inmates. Numerous sporadic cases are also on record. Authorities agree that it is more common in the spring months.

CLINICAL FEATURES.

The incubation period has been noted by many observers and may be stated to be 5 to 10 days, most commonly 7 or 8 days. The extreme limit may be longer.

The disease is principally one of childhood. Botschkowsky had the experience, apparently unique, of observing an epidemic of 54 cases in a battalion of soldiers. Apart from this, it is probably correct to say that at least 80 per cent. of recorded cases were under the age of 12 years, and the majority between the ages of 5 and 9 years. Park West's youngest patient was 7 months and the eldest 13 years. He had no case in an adult. Robertson has reported a case in an infant of 6 months. The youngest of Schäffer's cases was 4 months old and the eldest 16 years.

Adults, however, are certainly not immune. In the series of 464 cases there are 20 adults (excluding Botschkowsky's epidemic), the majority being young mothers of affected children; three patients were over 40 years of age. In adults the condition tends to be very mild and malaise slight, though Korsakoff saw a severe case with nephritis. There is no record of its occurrence during the war. The condition is, however, easily overlooked and may be mistaken for aberrant mumps, though one of us (H. L. T.) spent eighteen months in a hospital for infectious diseases in France without recognizing its entity or calling to mind its existence.

The onset is sudden, with the usual symptoms of an acute pyrexial attack in children: restlessness, loss of appetite, constipation, furred tongue, rapid pulse, and occasionally vomiting. Abdominal pain is sometimes present, and may be severe.

Enlargement of the Lymphatic Glands.

This may be present with the earliest symptoms or develop rapidly within twelve to forty-eight hours. The glands constantly affected are the cervical glands, deep to the sterno-mastoid muscle about the middle of its length. The enlargement is marked, and produces a definite swelling of the neck. On palpation several discrete glands are felt, often the size of walnuts. Robertson records glands as

large as a hen's egg in an infant of 7 months, and states that they were painless. The skin is not reddened, and the tissues are not oedematous.

The cervical enlargement is commonly unilateral at the onset. The glands on the opposite side frequently, but by no means invariably, enlarge later, usually within two to four days of the onset, but occasionally not until the first side has subsided to a varying degree. In Schäffer's series of 21 cases the cervical enlargement was unilateral throughout in 11, bilateral from the onset in 3, and affected first one side and then the other in the remaining 7. Some authors state that the left side is much more commonly affected than the right, but there is no definite agreement on this point. Other glands in the neck may enlarge subsequently, but to a much less extent. The initial enlargement is below the level of the angle of the jaw, and the position and general condition of the swelling differs from that of glands secondary to infections of the tonsils, teeth and nasopharynx.

The parotid and submaxillary glands are not affected. The submaxillary glands were enlarged in one case of Schäffer's and in one of Trautmann's, but not in others of their series. The parotid was enlarged in one case of Hirschelmann's, but it is doubtful if this group was really glandular fever. Enlargement of the parotid, submaxillary, epitrochlear and many other glands is referred to by Haas, but without quoting instances. By no other writers are they stated to be enlarged; nearly all have specifically mentioned their absence, and it may be accepted that the parotid and submaxillary salivary glands are not affected. The submaxillary lymphatic glands and possibly the preauricular gland may, however, be enlarged.

Enlargement of the axillary and inguinal glands has been noticed by most observers. Park West states that they were palpable in 75 per cent. of his cases, and enlargement has been recorded by Trautmann, Bellotti, Korsakoff, Haas and many others. Pfeiffer, in 1889, said that they were not affected, but Von Starck had noticed them in his series of 12 cases in 1890. Schiller did not find them in his 11 cases, and a few recorders of individual cases noted their absence. It may, however, be accepted that they are palpable in the majority of cases, but never attain the size of the deep cervical glands.

Pain and tenderness of the cervical glands may be entirely absent; there is usually some pain on movement of the head, but palpation of the glands even in the acute stages may be painless. Some pain and difficulty in swallowing may be complained of, and is referred not to the fauces, but under the level of the isthmus of the thyroid.

Enlargement of the mesenteric glands has been much discussed, and involved with this is the occurrence of abdominal pain. Pfeiffer noted pain in the abdomen as one of the characteristics, and stated that it was localized exactly in the mid-line below the umbilicus. Others have not supported this exact localization, and it may evidently be more generalized, but its presence has been repeatedly recorded. Byers does not mention its presence or absence in his group of 33 cases, but with this exception it is referred to by all others who have observed many cases. Park West states that some degree of abdominal pain or tenderness occurred in about 75 per cent. of his 96 cases. The pain may be very severe, as in specific cases published by Dawson Williams, Rudolf, and others.

The mesenteric glands may be definitely palpable. Many writers have not referred to them, but Korsakoff, Haas, Bellotti, and others record their presence. Jones states that they are palpable in 40 per cent. of cases. Park West said that he felt them in 37 of his 96 cases, and believed that the number would be larger if he had examined the earlier patients more carefully.

There is some evidence that the peribronchial glands may be affected. Von Starck in 1890 recorded the occurrence of a paroxysmal cough resembling whooping-cough, but without the whoop, and suggested that this was due to the pressure of enlarged peribronchial glands. Similar paroxysmal coughs have been noted by several French writers (Moussous, Comby, and Labbé); on the other hand, nearly all the writers state that no cough occurred and that no abnormal signs were present in the lungs. It may be accepted that the lungs are unaffected. The only recorded autopsy is Korsakoff's. There was definite enlargement of the axillary, inguinal, peribronchial and mesenteric glands, but in this case the cervical glands had supplicated.

OTHER SIGNS AND SYMPTOMS.

The condition of the tonsils and pharynx has been closely observed. Pfeiffer's attention appears to have been attracted to glandular fever owing to the disproportion between the size of the glands and the changes in the fauces. A slight reddening of the pharynx, he says, is the most that is present, and frequently there is no obvious change. Subsequent writers have fully confirmed his observation; thus Park West, Byers, Stark, Korsakoff and Schäffer record absence of tonsillitis in any of their cases, which make a total of 209. Stark's 30 cases occurred amongst children of the London area in whom diseased conditions of the tonsils and pharynx notoriously are very common. Park West states that in his series there were 29 cases with some reddening of the pharynx, and 4 had definite pharyngitis. It may be accepted that usually there is no obvious abnormality of the fauces, but that occasionally there is slight reddening of the pharynx, which bears no relation to the size of the glands.

No rash accompanies the condition; Heubner, who spoke at the same meeting as Pfeiffer in 1889, stated that in some similar cases he had seen urticaria was present. Korsakoff, in 1905, says that herpes labialis occurred often in his series, but the only other recorded case is one of Schäffer. Erythema multiforme is recorded in two cases by Tschaikowski; scarlatiniform eruptions occurred in one case of Botschkowski, and in one case of Harschelmann. Thornton published a case of glandular fever associated with erythema nodosum; this patient was a child of 5½ years, in whom a mitral systolic murmur was present on first coming under observation, and it is impossible to exclude the occurrence of rheumatic fever. There is no record of any other rashes, and these exceptions are obviously negligible in a series of 464 cases, mainly in children.

It may be accepted that there is no eruption associated with glandular fever.

Epistaxis may occur at the onset, which is not surprising if we are to regard glandular fever as an acute specific infection. It is, however, rare. The first instance was recorded by Chapman in 1897, among 5 cases in his own family, epistaxis occurring in 4. It also occurred in 2 cases of Trautmann's, in two of Schäffer's, and in 1 of Rudolf's. It is mentioned by Tschaiagajew and Comby. There is no record of other cases. When it takes place it is apparently profuse.

Vomiting occurs occasionally at the onset.

The pulse may be rapid, while the temperature is high, but cardiac complications do not occur.

Constipation was mentioned by Pfeiffer as being severe. It may terminate with diarrhoea or with the discharge of slimy motions at the end of the first week. The early writers refer to this sequence as almost a characteristic symptom of glandular fever, and considered that convalescence commenced with the discharge of mucus. Constipation, while evidently common, is by no means invariable, and it is doubtful whether much stress should be laid on it.

The liver and spleen are enlarged in a considerable proportion of cases. Pfeiffer noticed that in the severer cases both were palpable, and the majority of subsequent writers have confirmed this. Park West noted that the spleen became palpable in 57 of his 96 cases, and that the liver was enlarged in 87. Korsakoff did not note any definite relation between the enlargement of the spleen and the severity and duration of the illness. There is some disagreement as to the frequency with which the spleen is palpable. Byers, recording 33 cases, does not mention the liver or spleen, and possibly may have overlooked them. Stark mentioned the spleen only once in 30 cases, nephritis being present in this instance. Schäffer states that the liver and spleen were not palpable in any one of his 21 cases. On the other hand, Jones, who refers to 20 cases, states that the spleen was palpable in 80 per cent, and the liver in 90 per cent., and Schiller felt the liver and spleen in each of his 11 cases. Such differences may be partly due to variations in different epidemics and series of cases. Probably it is partly due to individual observers, since it is well known that the recognition of the tip of the spleen is frequently a matter of difficulty and doubt.

From a general study of the literature it appears undeniable that the spleen is palpable in a considerable number of cases, which may be placed at about 50 per

cent. Pfeiffer states that it usually becomes palpable at about the fourth day, but there are no other observations for checking this opinion. In our case it was just felt on the third day and easily palpable on the fourth.

The temperature usually rises to 101° to 103°, occasionally it may be as high as 104°. It corresponds roughly with the size and duration of the marked glandular enlargement, usually being maximum on the third or fourth day, then falling rapidly and becoming normal early in the second week. When the onset is unilateral the temperature may fall as this side subsides, and then rise again as the opposite side enlarges or if it recurs on the same side. Schäffer noticed such relapses in 10 cases. In mild forms there may be no rise of temperature, as noted by Schäffer and others. In Botschkowsky's 54 cases in adults 10 were apyrexial. The fall may be so rapid as to suggest a crisis, as in some cases of Park West and Von Starck, but usually it is more gradual.

Bacteriological investigations have been principally directed to cultures from the fauces, and, as may be expected, they resulted in the growth of streptococci, staphylococci and pneumococci, with influenza bacilli in a certain number of cases. The earlier observers dealt very fully with these investigations, but little importance will now be attached to them.

Cultures from the glands themselves have been made only in a few cases in which suppuration occurred, and in these streptococci have always been present. In Korsakoff's fatal case streptococci were found in the heart blood and other sites in cultures taken twelve hours after death. The glands had suppurated and the child died with the symptoms of septicaemia. Tschaikowsky claimed that in 3 cases he isolated influenza bacilli from the blood during life. As Schäffer points out, these results must be accepted with caution, as it is stated that the bacilli were isolated on a simple agar medium without blood, and subsequent subcultures were grown on the same medium. Schiller found influenza bacilli, together with streptococci and staphylococci, in the pus from a gland. Loude and Froin in one case isolated pneumococci from the blood. The patient's father had had lobar pneumonia three weeks previously, and they suggest that this was a direct infection.

A general review of the bacteriological investigations reveals nothing specific.

There are very few records of examination of the blood, and these are either scanty or made in cases in which suppuration of the glands had occurred. Jones gives the following results in two cases:

Case 1.—On sixth day, leucocytes 14,900 per c.mm.; on ninth day, leucocytes 8,900 per c.mm.; red cells 4,000,000 per c.mm.; haemoglobin 90 per cent.

Case 2.—On eighth day, leucocytes 7,000 per c.mm.

In one of Rudolf's cases the glands subsided but enlarged again a month later and suppurated. When it was suspected that pus was forming frequent blood counts were carried out, but "showed no leucocytosis."

Just before the operation the blood count was: Leucocytes, 7,000 per c.mm.; red cells, 4,500,000; haemoglobin, 80 per cent.; polymuclear neutrophils, 60 per cent.; no abnormal cells. After the operation the number of leucocytes was "about doubled" for a few days.

These are the only instances in which definite blood counts are referred to, and no other details are given. Many observers mention the subsequent development of anaemia and its obstinate character.

Complications are rare. Nephritis is the most important. It was mentioned by Heubner in remarks made at the meeting at which Pfeiffer read his original article, and has been referred to by many subsequent writers. When it occurs it is frequently, usually in severe cases, stated to be a "haemorrhagic nephritis." The onset is at the commencement of the illness or within a few days. There is no record of the occurrence of oedema. All writers agree in stating that nephritis never becomes chronic, but the evidence is scanty and cannot be regarded as conclusive. The summary of the statistics given in articles in which both the total number of cases and the number of cases of nephritis is given shows 17 instances of nephritis in a total of 270 cases—an incidence of 6 per cent. There is no record of the occurrence of purpura, or of any other form of haemorrhage except the initial epistaxis.

Suppuration of the glands is a very rare occurrence, indeed the earlier writers deny that it ever took place. Only 9 instances are recorded in the literature. One of these, Korsakoff's, was fatal. In all cases in which bacteriological investigations were made streptococci were present; staphylococci or other organisms are also mentioned occasionally. In Rudolf's case the glands subsided, but enlarged again one month later and then suppurated. In all recorded cases the suppuration was confined to the cervical glands.

Otitis media is recorded in 4 cases—in 2 of Schäffer's and in 2 of Durno's. In one of Schäffer's cases the glands had suppurated. There is no mention of otitis media elsewhere in the literature.

Pulmonary complications are confined to the observations of a paroxysmal cough referred to above. Coryza is mentioned by one or two writers, but most observers definitely refer to the absence of any catarrh. There is no record of the occurrence of orchitis, and the diagnosis of pancreatitis has never been made.

PROGNOSIS.

The prognosis is favourable. The enlargement of the glands usually reaches its maximum about the third or fourth day, and after a further two or three days the glands rapidly diminish in size. At the end of one to two weeks there is no visible swelling, the temperature is normal, and definite symptoms of malaise have passed away. Recurrences are not infrequent, and, as has been mentioned above, there may be either an enlargement of the glands on the opposite side to that originally affected or a return of swelling on the same side. Such recurrences are accompanied by pyrexia and prolong the acute stage.

The slowness of convalescence has attracted the notice of many observers. The glands, though no longer visible, often remain palpable for many weeks or even months. Anaemia is frequently referred to as developing during convalescence and persisting for a considerable time. The general health is poor during this period. Complete recovery finally takes place. No second attacks have been recorded.

Only four fatal cases are recorded in the literature. In Park West's fatal case the child had been previously in poor health. Bellotti had two fatal cases in children, aged 1½ and 3 years; both began with the ordinary symptoms and the glands subsided, but cachexia developed and was finally fatal. In Korsakoff's case the cervical glands suppurated.

This is the only instance in which an autopsy is recorded, and, unfortunately, findings are complicated by the probability that death was due to septicaemia. The cervical, peribronchial and mesenteric glands were greatly enlarged, and the axillary and inguinal glands slightly. Microscopic sections of the glands were said to show hyperplasia of the parenchyma, with signs of inflammation. There was no evidence of tuberculosis; or lymphadenoma; ecchymoses were present on the pleura; the spleen was in the left pleural cavity was 8 oz. of fluid. The spleen was enlarged. The kidneys were in a condition of glomerulonephritis. Streptococci were present in the pus of the cervical glands before death, and twelve hours after death were isolated from the axillary glands, liver, spleen, kidneys, bone marrow, and heart blood.

The following is the account of a case which has been under our observation:

C. G., male, aged 8 years. First seen on July 1st, 1920. Had been previous health very good. Measles in April, 1920. The somewhat irritable for three or four days previously. The parents noticed swellings in the neck on June 30th, and on July 1st the father noticed that the glands were enlarged "all over the body." Slight nausea on previous day, but no vomiting. The general condition was good. He had a good colour and no evidence of anaemia. There was no sore throat. On examination: The lymphatic glands in the neck were markedly enlarged. Deep to the sterno-mastoid and about the middle of its length on both sides were several glands about the size of walnuts, causing a definite prominence in the neck, especially on the right. There was no superficial oedema, and the glands on palpation were discrete, suggestive of the condition found in Hodgkin's disease. Palpation was almost painless. On the right side the superficial submaxillary

lymphatic gland was greatly enlarged and bulged away from the jaw. It could be distinguished from the deeper lying salivary gland. The other glands in the neck were also enlarged, but to a much less degree. The axillary glands were enlarged on both sides. In the groin there were two large glands on the right side and smaller ones on the left. In the abdomen two large mesenteric glands were easily palpable just to the right of the umbilicus and slightly below it, and they were somewhat tender. It was thought that the tip of the spleen could be felt. There was no purpura or haemorrhages. The tongue was slightly furred. The fauces showed no abnormality and the mouth was quite clean. The heart and lungs were normal. The urine contained no albumin or sugar, and remained normal throughout. There were no septic foci in the scalp, ears, or elsewhere except one carious molar on the left side, which was painless. The temperature was 102°. On July 3rd the temperature was 103°, but the general condition remained good, and the boy was hungry and wished to be allowed to get up. All the glands were larger and the spleen was now definitely palpable. On July 4th the temperature fell rapidly, almost suggesting a crisis. The glands in the neck were distinctly smaller, but the spleen was now nearly two finger-breadths below the costal margin. The other glands were unchanged. The bowels were opened freely on this day, constipation having been present previously. On July 5th the glands in the neck were again smaller and continued to diminish rapidly from this date. The remaining glands, however, diminished more slowly. By July 11th the patient felt perfectly well and was allowed up. The glands

were still diminishing and the spleen was only just palpable. On July 18th the spleen was no longer felt. The glands in the groin appeared slightly larger and the other glands about the same as a week previously. The child appeared somewhat paler than before, and the mother said that he was easily tired.

Subsequently progress was uninterrupted, but the glands, even at the present time, remain palpable. The blood counts are recorded in tabular form. The percentage of lymphocytes is very striking. It rose to a maximum on July 5th and then probably commenced to diminish, at first rapidly and then more slowly, and it is now approaching normal. The large and small lymphocytes are classified together, but throughout large lymphocytes predominated, and on July 5th formed

72 per cent. of the total white cells. There were no abnormal leucocytes and no abnormal erythrocytes. Apparently there was a slight but persistent anaemia. The Wassermann reaction was negative.

Other children in the family were not affected, but the patient was isolated early in the attack.

It is probable that a patient under the care of one of us at the Great Northern Hospital was also an example of glandular fever.

This was a boy, aged 7 years, admitted on December 8th, 1920. Malaise had commenced twelve days previously, and after two days the glands in the neck were noticed to be enlarged. They subsided rapidly, and after a few days in bed he was allowed to get up, when it was noticed that the urine was "blood red," and also that the face was swollen. The red urine lasted about a week. On admission he looked pale and the glands in the neck were palpable. The fauces were clear. There were a few small glands in the axillae and groin. The

urine contained albumin and casts. The blood count on December 16th was as follows:

Leucocytes	13,500 per c.mm.
Polynuclear neutrophils	60 per cent.
Lymphocytes	31
Eosinophils	2
Large hyalines	5

A trace of albumin was still present on discharge on December 31st. There were six other children in the family, none of whom were affected.

A third case has also been under observation at St. Thomas's Hospital, but the glands had almost subsided when the patient was first seen. The blood and urine were normal. Another child in the family had been similarly attacked about a week previously.

ETIOLOGY AND PATHOLOGY.

The nosology of the disease presents several questions. Is it an acute infectious disease? If so, is it a specific disease or an aberrant form of some common fever?

The evidence that it is infectious is sufficient to be accepted as proof. Pfeiffer stated that it occurred in small, limited epidemics and in house epidemics, and while numerous sporadic cases have been recorded, there is sufficient evidence that his statements are correct. Fisher, in 1897, noted 8 cases and Chapman 5 cases in one family, and numerous instances are recorded in which several members of a household have been attacked. It has been observed frequently when this occurs that the interval between successive cases is about seven days, all the members not being attacked simultaneously. For example, this was the interval between the two cases in Rudolf's family, and Park West states that when two children of a family are affected, the second case most commonly commenced on the seventh day after the first.

Examples of more widespread epidemics have been given above, the largest being Park West's 95 cases in forty-three families widely scattered over a large area. Park West noticed that the infection spread irregularly.

The view that it is an acute infectious fever is consistent with the general course of the illness, with the occasional occurrence of epistaxis, with the occurrence of nephritis, and with the observation that treatment has no effect on the course of the acute stage.

Admitting that glandular fever is infectious, the question arises whether it is a specific disease or a variant of some common fever. The similarity to mumps is superficial rather than real. Evidence has been given above that the parotid and submaxillary salivary glands are not affected in glandular fever, and there is no recorded instance of orchitis. In mumps the swelling frequently commences behind the jaw just below the ear, but it is characteristic of glandular fever that the site of the enlarged glands is definitely lower than this—that is, about the middle of the length of the sterno-mastoid muscle. A decisive argument for the distinction of the two diseases is the number of instances in which children with glandular fever have previously or subsequently had an attack of mumps. This occurred in 54 of Park West's cases, and Byers also notes that several of his 33 cases had previously had mumps. With regard to exanthemata, rashes do not occur in glandular fever, and even in the larger epidemics no intermediate cases have been recorded.

The mode of spread in epidemics is sufficient to eliminate syphilis, although in the diagnosis of a sporadic case it might have to be considered. There is no record of any Wassermann reaction. The general type of the glandular affection is unlike syphilis, which does not tend to produce a very marked enlargement of the cervical glands. Again, the mode of spread is unlike tuberculosis. In Korsakoff's fatal case the glands examined showed no signs of tubercle. There is no other record of a microscopic examination of a gland.

Many of the earlier writers considered that glandular fever was a form of influenza. At the present time no one knows what influenza is, but it is noteworthy that the last article on glandular fever in the literature was published in 1914, and it is consequently justifiable to assume that it is not influenza as we have known it in recent years.

With regard to infection from the fauces—another suggested cause—it has been pointed out above how very little change is recognizable at this site. Tonsillitis is practically unknown. Pharyngitis is very uncommon and rarely exceeds slight reddening, yet several authorities have upheld the theory of pharyngeal infection. Trautmann argues on anatomical grounds that the glands

affected are those supplied by lymphatics from the pharyngeal tonsil. Most of these writers have ascribed the infection to streptococci on the strength of their presence in cultures from the nasopharynx. This cannot be accepted as an argument of any weight in view of the now known frequency with which streptococci occur in this position. The great enlargement of the cervical glands and the enlargement of the spleen and other glands, together with the rarity of suppuration and the very low mortality, is not consistent with a streptococcal origin. Even when some pharyngitis is present, it is characteristic of glandular fever that the size of the cervical glands is out of proportion to the symptoms and signs in the fauces.

Most French writers refuse to accept glandular fever as a disease *sui generis*. Thus Gallois regards it as only "a special form of influenza," and Labbé as a "cervical adenitis due to a naso-bucco-pharyngeal infection similar to any other acute adenitis." Combemale believed it to be Hodgkin's disease, but the subsequent history of the patients, which in some cases has been watched over prolonged periods, is against this view. Von Starck, noting the occurrence of constipation and of anal diarrhoea, discusses the possibility of an auto-intoxication from the bowels. Subsequent writers have often quoted him as accepting this origin, but reference to his article shows that he rejected it.

It appears that glandular fever must be accepted as an acute infection and as a general and not merely a local infection. Further, there is no evidence to connect it with any of the better known acute infectious diseases, and we agree with those who regard it as a disease *sui generis*.

Various epidemics have been recorded which more or less resemble glandular fever. Breul, Priestley and Fielding described in 1914 an endemic glandular fever which occurred in North Queensland, and was known locally as Mossman River fever. Many hundreds of cases have occurred since 1877. Adults are principally attacked, and it is rare in children. The onset is gradual, with pyrexia for ten or more days, the glands enlarge slowly, and the axillary and inguinal glands are mainly affected. At the onset the blood is normal, but about the end of the first week leucocytosis develops, the white cells being 12,000 to 15,000 per c.mm., with 45 per cent. of lymphocytes, and there is some degree of anaemia. The mortality is under 1 per cent. The glands show a simple adenitis. It is supposed that the infection is spread by mosquitos. It is evident that this is not glandular fever of the type which we are discussing.

Several writers have described outbreaks of epidemic cervical adenitis, especially Sharp, Pruett and Kirkland in 1913 and 1914. The changes in the fauces were marked, tonsillitis was common with exudation or even membrane formation, but diphtheria bacilli were not present. Tonsillar abscess was not infrequent. The cervical glands alone were affected and the spleen was not enlarged. Kirkland says that blood cultures, when positive, and swabs from the throat, showed streptococci. These epidemics would appear to be a definite infection of the tonsils with secondary enlargement of the cervical glands, and the clinical symptoms and course do not agree with glandular fever.

DIAGNOSIS.

Diagnosis has to be made from mumps, acute cervical adenitis secondary to septic foci, acute leukaemia, exanthemata, acute lymphadenoma, syphilis, tubercle, and possibly influenza.

From mumps, glandular fever is distinguished by the position of the initial and main enlargement of the glands being below the angle of the jaw, and by the freedom of the salivary glands, the parotid and submaxillary. The tissues of the neck are not oedematous, and much pain is rare. A previous attack of mumps may have occurred. It must be noted that, though the salivary glands invariably escape, certain lymphatic glands in proximity to them may be involved, producing the impression that the salivary glands are affected. Thus, in one of our cases, the superficial submaxillary lymphatic gland was greatly enlarged and produced a large prominence on the jaw, but examination easily proved that this was not the salivary gland. Possibly the pre-auricular lymphatic gland may sometimes be enlarged, and no doubt an erroneous diagnosis of mumps might be suggested.

Group II.

(a) Non apposition of fractured ends from various causes—for example, interposition of soft structures; over extension with weights; loss of bone.

(b) Movement between apposed ends.

(c) Prolonged severe infection.

With reference to Group I: Comparatively little is known about (a), but pituitary extract is certainly worth a trial; (b) is an important factor, and everything possible should be done to encourage use consistent with prevention of movements at the site of fracture. It is here that massage plays an important part. As regards (c) the blood supply may be injured originally or later cut off by formation of fibrous tissue, and either of these conditions certainly leads to very delayed union.

Under Group II are classed those causes of non union which may be called lack of opportunity. The non apposition of fractured ends is, I think, by far the greatest cause of non union, and this is, in the great majority of cases, produced by the interposition of some soft structure.

The practice, as was advocated by Leriche, of wholesale removal of all bony fragments in compound comminuted fractures is to be condemned.

Movements between the fractured ends is, I believe, another very common cause of non-union or delayed union, and I venture to state that far more damage has been done by neglect of really adequate splinting than good has accrued by the much vaunted early movements, which have often been instituted regardless of all other considerations.

Treatment.

Due regard must be paid to the general condition of the patient. Inducing the patient to drink large quantities of milk and the giving of calcium salts I believe to have no beneficial effects. Doses of anterior lobe of pituitary, 10 grains daily, by mouth, of fresh gland, or subcutaneous injections of extract of anterior lobe, are well worth a trial, especially in those cases of delayed union which are particularly common in the tibia. During the administration of pituitary the urine must be examined for sugar, and the administration stopped or dose reduced if glycosuria becomes marked. I have not as yet got sufficient data to make any positive statements on the influence of pituitary extract.

The most important part of the treatment will be that directed to the local condition. Here massage and electrical treatment are important to improve and maintain nutrition and keep all the surrounding structures in good condition. Movement and use should be encouraged whenever possible—for example, the wrist and hand in cases of ununited humerus. Where infection is still present this must be cleared up, and an interval of at least three months allowed after healing; during this time special attention should be paid to all joints and soft structures, and use of the whole part encouraged, a temporary splint or support being used the while to allow of maximum use. Deformities should be corrected where present.

This delay for the clearing up of slightly infected cases is not always a necessity; it depends upon the type of operation contemplated. I have treated several cases of non union of humerus in which there has been a sinus, and obtained excellent results by a step operation or dovetailing and providing drainage.

It is sometimes desirable to perform two operations. At the first scar tissue is excised and the sclerosed ends of bone removed; the wound is then completely sutured and the main operation done a month later. This preliminary operation is the more indicated in those cases where prolonged infection has been present and a bone graft is contemplated, for it will serve not only the purpose of eliminating unhealthy tissue, but also as an indicator that infection is absent.

Injured nerves are best dealt with after union has taken place and proper treatment can be devoted to the part; it is seldom possible adequately to treat the two conditions concurrently. Of course, nerves merely caught in between the bone ends and adherent must be freed, but, on the whole, I prefer to interfere with the nerve as little as possible at the time of operating on the fracture.

The operation consists in (1) attaining apposition; (2) retaining apposition without possibility of movement between the ends.

(1) Attaining apposition is done by the most convenient route to muscles, nerves, and vessels. If fibrous tissue. Most or all of the sclerosed bone is removed and several holes made with a fine drill. The method of actually attaining apposition will depend upon the bone and the condition of the bone ends—for example, 3 in. shortening of a humerus is a trifling matter causing little disability, but it would be a most crippling

deformity in a tibia. The methods employed are (1) the "slot or dovetailing" method, (2) the "step" method, (3) the sliding bone graft, and (4) bone transplantation, the slot being filled with an accurately fitting piece of bone cut from some other bone, usually the tibia.

The last is the most successful type of bone transplantation to use. Intramedullary pegs of bone, where they are used to bridge a gap, are prone to fracture after a period of time. Sometimes it may be desirable to transplant a whole piece of bone—for example, a piece of fibula. Speed is of importance directly bone is exposed, as it dries very quickly, and to prevent this the parts must be kept bathed with warm normal saline. In every case the ends are securely bound together by drilling holes and using thick thirty day chromic catgut. When this has been done quite good stability is obtained, and the operation cannot be regarded as satisfactory unless this is so, particularly in cases of bone graft.

It is to be noted that many patients have a rise of temperature for a few days after the operation, but this is not to be taken as an indication for opening up the wound unless the rise of temperature is maintained. In a few cases where there is extensive scarring, the skin may slough, and this condition is best treated with spirit dressings, thereby the necrosed area is kept sterile and in a short time an aseptic scab will be formed without infection of the deeper tissues of the wound.

The whole limb is then put up in plaster, paying particular attention to fixation of the joint above and below. On no account should plates, wires, screws or other non-absorbable substances be used—they are unnecessary and almost without exception injurious. A radiogram, through the plaster, may be taken in a day or so, to see that all is well.

In cases where dovetailing or step operation has been performed the plaster can be removed at the end of six to eight weeks and a radiogram taken, after which the plaster is reapplied. It is usual to find that there is sufficient union to permit of limited movements being instituted in one of the joints. At the end of three months the plaster can be replaced with a detachable support, applied to afford protection from severe strains, but allowing of free movements of all joints. During this period the patient is encouraged to use the limb, and massage and electrical treatment is applied.

After a bone graft or transplantation, it is wise not to remove the plaster before the end of three months, and it should then be reapplied for another three months and a protective splint used for a further period. The time in plaster will depend upon the condition found in the radiogram.

The length of time during which a bone has been ununited seems to have little influence upon the ultimate prognosis, and a period of years of non union should not deter one from operating with a reasonable certainty of a good result.

THE TREATMENT OF HAEMORRHOIDS BY ELECTROLYSIS.

BY

J. CURTIS WEBB, M.A., M.B., B.Ch.

In the earlier part of 1914 I read a paper at the Royal Society of Medicine on the treatment of haemorrhoids by electrolysis, and I referred there to the very satisfactory results which I had obtained by this method. During a great portion of the four and a half years of the war, which I spent in Boulogne, I had many opportunities of carrying out this treatment, and the more I see of its results the more convinced I am that, in suitable cases, it is the method of election for this very troublesome complaint. For the sake of convenience haemorrhoids may be divided into three classes:

1. *External*, which occur at the mucocutaneous margin of the anus, and are due to varicosity of the inferior haemorrhoidal branches. These as a rule give no trouble unless they become

inflamed and thrombosed, and for such I believe the best treatment is an incision and removal of the clots.

2. *Internal*, which do not prolapse, and which give rise to no symptoms. The operation is not usually accompanied by danger—and painful, and I have found that the large majority of such cases can be cured by applications of the high frequency vacuum tubes, aided by suppositories containing adrenaline.

3. *Intero-external*, which prolapse and become "nipped" by the sphincter, giving rise to great pain, and, frequently, both haemorrhage and discharge. These, and true internal haemorrhoids, are usually dilated at the junction of the superior and middle haemorrhoidal veins.

It is for the last named very common type of pile that patients usually apply for relief, and for which sedative and astringent ointments and suppositories afford little permanent benefit.

I am convinced that the treatment by electrolysis is the most certain and the least painful. No general anaesthetic is required, and the patient is not confined to bed, as a rule, for more than twenty-four hours at most. There is no pain on defaecation after the treatment, nor reflex difficulty in emptying the bladder, and the cure, as far as the haemorrhoid treated is concerned, is permanent. The prolapsed pile is treated in the manner to be described, and the patient then left alone for ten to fourteen days. If at the end of that time there is another haemorrhoid in evidence it can be treated in a similar manner, but I have never had to administer more than three treatments in any case, and this only on one occasion.

Method.

The patient, having had the bowels thoroughly cleared out by an aperient over-night and a saline in the morning, is placed on the left side, and a large indifferent electrode, connected to the negative terminal of a source of constant current, is applied over the right buttock and hip, taking care that it is in close apposition with the skin. If the haemorrhoid is not fully prolapsed the patient is asked to strain to bring it down. The pile is now painted with a mixture of phenol gr. 30, menthol gr. 30, quinine hydrochlor. gr. 22, adrenaline gr. 1, 100, which I have found to be the best "surface anaesthetic," and after a minute or two it will be found that a local anaesthetic can be injected into the tissue below the base of the haemorrhoid without pain, provided that a sharp fine needle be employed. I usually employ sol. urea and quin. hydrochlor. (Parke, Davis and Co.). After about ten minutes the pile is completely anaesthetic, though almost immediately after being painted it can be painlessly grasped with artery catch forceps to prevent its retraction. Two or three long zinc needles, or thin spears made from "slivers" of sheet zinc and soldered to flexible insulated wire, are thrust into the base of the pile parallel to its long axis, and several more into the substance of the pile. All these needles are connected to the positive pole of the source of current, and are packed round with oiled wool to prevent their causing blisters on the parts round the anus. The current is now slowly turned on till a strength equal to about 12 to 15 milliamperes per needle is reached, and is allowed to flow for ten or fifteen minutes and then gradually turned off. It will be found that the needles are quite difficult to withdraw owing to the firmness of the clot formed, and it is often well to reverse the current, making the needles negative, for a couple of minutes to facilitate withdrawal.

After the treatment the pile has changed from purple red to grey. It is covered with adrenaline and chloretone ointment and pushed well up into the rectum, and a suppository of chloretone gr. 5, morphine gr. $\frac{1}{4}$, and novocain gr. $\frac{1}{2}$ inserted. The patient is sent home with directions to go to bed for twenty-four hours, to take a dose of senna and sulphur the following night, and is also instructed that, should the pile prolapse, it must be replaced at once.

The process by which the haemorrhoid is cured is two-fold. The vasa vasorum are obliterated, and thus the blood supply is cut off from the walls of the vein, and at the same time a firm, closely-adherent clot is formed in the lumen of the dilated portion.

Advantages of the Method.

1. It is practically painless at the time of treatment.
2. There is very little, if any, pain afterwards.
3. The patient is not kept away from his work.

4. There is no risk of separation of the clot as far as my experience goes, or in the experience of others who have used this treatment.

5. There is no necessity to dilate the sphincter.

I do not consider this treatment is indicated in cases where the piles do not protrude, nor when they are very large.

I do not propose to quote a series of cases, but two recent ones are typical:

A lady, 75 years old, had for two years suffered from small prolapsing haemorrhoids, constant discharge from the anus which stained her linen, and intense pruritus. Two treatments at an interval of ten days, which caused her absolutely no pain either at the time or afterwards, had effected a complete cure of the haemorrhoids, of the discharge, and of the pruritus.

A medical man in busy general practice who had had a prolapsing pile for eighteen months, and discharge and pruritus, was treated on a Saturday afternoon. He had some pain that night, but visited his patients on Sunday and every subsequent day. He has had no trouble since that one treatment.

These results are typical of what one may expect with careful technique in suitable cases.

TUBERCULIN IN EPILEPSY.

BY

JAMES CROCKET, M.D., CH.B., D.P.H.,

LECTURER ON TUBERCULOSIS, GLASGOW UNIVERSITY; MEDICAL SUPER-INTENDENT, CONSUMPTION SANATORIA OF SCOTLAND AND COLONY OF MERCY FOR EPILEPTICS, BRIDGE OF WEIR.

For many years we have administered tuberculin with excellent effects to at least two hundred patients each week. These patients chiefly suffer from chronic ulcerative pulmonary tuberculosis and tuberculous adenitis, and are resident in the Consumption Sanatoria of Scotland, the Colony of Mercy for Epileptics, and the Orphan Homes of Scotland, Bridge of Weir, Renfrewshire.

Two cases particularly are interesting, and deserve to be recorded. Some textbooks¹ on the subject of tuberculin mention epilepsy as a contraindication to its administration. Our experience shows that, so far from that being so, it is a decided indication for its use, especially under two circumstances: (1) the presence of a tuberculous lesion, active or quiescent; (2) a family history of tuberculosis.

Six and a half years ago we began to give tuberculin to a patient (A. D.), who was 32 years of age, who had suffered from epilepsy of the major type since the age of 7, and who had a large mass of tuberculous glands below the right ear with several discharging sinuses; the mass was as large as a closed fist. There was a smaller mass supraclavicularly on the left side, and chronic pleurisy at the left base. No other change was made in the patient's life—the environment, work, and drug treatment were the same as had been the case for many years. We hoped by tuberculin to help the tuberculous con- dition, and had no thought of it benefiting the epilepsy. In the course of a year and a half the glands disappeared entirely and the pleurisy cleared up. *Pari passu* with the disappearance of the tuberculous lesions, the epileptic fits became fewer and after two and a half years ceased entirely, and the patient likewise improved mentally. When the fits had been absent for a period of three years the patient was discharged from the colony, and she took up work as a domestic servant. We have kept her under observation and under tuberculin treatment during the year, and she has remained perfectly well. For four years thus, apparently as the result of this one new factor—the administration of tuberculin—this patient has been free both from tuberculosis and from epilepsy.

Encouraged with the results of treatment in this case, about eighteen months ago we began to administer tuberculin to several other epileptics who had no clinically obvious or apparent tuberculosis, but gave a family history of tuberculosis. One of these (F. A.) has responded excellently. He was 14 years of age, and had had epilepsy for an indefinite period—the father could not tell how long. His mother had died of consumption. The fits were very severe in character, and one month no fewer than 338 were recorded—309 major and 29 minor. He was decidedly weak-minded, and was certified under the Mental Deficiency Act (1913) as a mental defective. Tuberculin was first given to him in November, 1919. For nearly fourteen months he has had no signs of epilepsy, and mentally he has also improved. The records of his case show that previously he was pugnacious and irresponsible, but during the past year he has been well behaved, and fairly industrious.

Five others, to whom tuberculin has been given for six to twelve months, show a diminution in the number and in the severity of their seizures. Three show no change. We have begun to give tuberculin to a hundred epileptic

patients, ignoring the presence either of a tuberculous lesion or of a hereditary strain. It is well known that *post-mortem* results point to the vast majority of those who attain maturity presenting tuberculous lesions at some part. It will be interesting in course of time to note the results.

The action of the tuberculin in epilepsy as demonstrated in those cases is uncertain. It may be due to its specific effect on some tuberculous growth in the neighbourhood of the cortex. It may be that epilepsy that is tuberculous in origin is of the Jacksonian type. This drug certainly does lead to the resolution of masses and of adhesions which are palpable, and such masses or adhesions may reflexly lead to the onset of epileptoid seizures.

The tuberculin used was Burroughs, Wellcome and Co.'s B.E. and P.B.E. mixed in equal parts, and it was given in doses beginning at 0.00000001 c.cm., gradually increased to 0.4 c.cm. The injections were given at intervals of seven days to begin with, and later of fourteen days. The treatment has gone on without any intermission. General reactions have been avoided, but once or twice local reactions of a rather severe type occurred when large doses of bacillary emulsion were given. On two occasions cold abscesses formed, which had to be aspirated.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SAPRAEMIC GLYCOSURIA.

I HAVE read Dr. C. G. Higginson's article on supraemic glycosuria (February 26th, 1921, p. 296) with interest, as I have at present under my care a patient who developed glycosuria shortly after a carbuncle appeared on his neck.

My patient, a stout and previously healthy man of 64, consulted me some three weeks ago for a large boil on the nape of his neck. His urine contained no trace of sugar. In spite of topical applications the carbuncle spread rapidly, and I made a deep crucial incision throughout its extent; it continued to spread until it extended almost from ear to ear, with a breadth of some 3½ in. He was seen by a surgeon, who excised the whole of the affected tissue, leaving a large gaping wound.

Previous to the operation I volunteered the information that there was no glycosuria. Two days later the patient complained of thirst; the temperature was subnormal throughout. I again examined the urine, and found that it contained 17 grains of sugar per ounce. A diabetic regimen reduced the sugar to 4 grains per ounce in twenty-four hours, and in forty-eight hours it had completely disappeared, and has not been present since. After a period on strict diet the patient returned to ordinary diet; in spite of this he has had no further glycosuria.

Some two years ago I saw another patient with a tiny black pith on his great toe; he had 54 grains of sugar per ounce in his urine. Gangrene set in with great rapidity in spite of strict diet, and soon involved the whole foot; he also began to exhibit symptoms of impending coma. He fasted completely for four days, when the amount of sugar became reduced to 4 grains per ounce. He was then put for a time on a diet, gradually increased, of eggs and French beans, and the sugar soon disappeared. I eventually amputated his foot. He did well, and now gets about with an artificial limb. With a diet containing no sugar, but with a moderate amount of bread and one potato daily, his urine remains sugar-free, but on one occasion when he exceeded his limit of starchy food, sugar reappeared freely, to disappear again on resumption of previous restrictions.

Some years ago I had a case of carbuncle in a diabetic which, in spite of dietetic restrictions current at the time, continued to spread, the patient eventually dying of diabetic coma.

There would appear to be two types of cases—one in which the carbuncle or gangrene is the sequel to the diabetes, and the other in which the carbuncle or gangrene is the causative agent of a supraemic glycosuria, or perhaps coincident with and due to an intermittent glycosuria.

I shall be interested later on in estimating the sugar tolerance of my present patient, but shall prefer to wait for his complete recovery. The success of the Allen treatment, as expounded by Dr. Leyton, in my case of gangrene has made me think that such treatment might be generally useful in cases of diabetic gangrene, whether the gangrene be cause or effect.

Old Hill, Staffs.

THOMAS E. MITCHELL, M.B.

IN THE BRITISH MEDICAL JOURNAL of February 26th Dr. Charles Gaskell Higginson finishes his paper on supraemic glycosuria with the sentence:

"At present gangrene and carbuncle are the most striking and misleading agents in the causation of supraemic glycosuria, but further investigation will doubtless reveal a long series of such agents differing from each other very much in the power of causing supraemic glycosuria."

This prophecy has led me to record some observations which may throw a light upon the condition. The percentage of sugar in the blood of a healthy man six hours after food may be taken as 0.11, and although sugar may appear in the urine with this blood sugar, it is the exception rather than the rule; usually the blood sugar is above 0.18 per cent. in glycosurics. In pyrexia the blood sugar rises above the normal, and this is so well known that the appearance of glycosuria gives but little more anxiety than albuminuria in pyrexia.

Everyone who has had experience in the treatment of diabetes realizes that toxins produced by most infections modify metabolism sufficiently to lead to a return of sugar in the urine whilst the patient maintains the diet which was the optimum, and had permitted the blood sugar to fall to normal. The quantity of toxin may be small. I have seen the injection of one hundred million dead bacilli cause glycosuria in a woman who was upon a diet of only half her optimum. The reappearance of sugar in a diabetic child permitted of the correct prophecy, three days before their appearance, that she would develop the spots of chicken-pox. (The sister was convalescent from that disease.)

The supraemia of pyorrhoea alveolaris is so common and important a factor in diabetes mellitus that extirpation of the infection has often led to the disappearance of glycosuria with but an insignificant modification in diet. The evidence upon which this is based is rather lengthy. The causes of glycosuria are so numerous that any tentative explanation offered is offered with all humility. It seems to me probable that one form of diabetes mellitus is due to a deterioration of the cells of the islands of Langerhans in the pancreas. This deterioration is sometimes due to a direct infection accompanied by a slight pyrexia for a few days. Some of the cells are destroyed, some impaired, and others left normal. The impaired cells have a reduced vitality and may be paralysed or destroyed by various toxins. Chloroform and ether often destroy them and turn a mild diabetes into a severe one. A mild toxin may lead to a temporary glycosuria from which recovery may be complete. I tend to the view that supraemic glycosuria and glycosuria due to non diabetic gangrene are simply two varieties of toxic glycosuria.

London, W.

O. LEYTON, M.D., D.Sc., F.R.C.P.

NORMAL DELIVERY AFTER TRAUMATIC RUPTURE OF UTERUS.

IN view of the interest aroused by the discussion at the Royal Society of Medicine, in May of last year, on spontaneous rupture of the uterus during labour, following Caesarean section, I think the following case, unique I believe, will be of interest.

A married woman, aged 22, five months pregnant, fell from a railway platform on to the rails, rupturing the uterus. I examined her two, seven, and eleven hours after the accident, and the uterus appeared normal. As at the last examination she showed symptoms of internal haemorrhage, I diagnosed concealed haemorrhage, and, turning her on to the left lateral position, tried to rupture the membranes. As I was unsuccessful in this, I got Dr. Gordon Ley to see the case. He saw her fifteen hours after the accident, and decided to open the abdomen. When this was done, he found the uterus ruptured on its anterior surface for about 9 inches, and the foetus and membranes lying in the abdominal cavity. I believe the foetus had slipped out of the uterus, when I put the patient into the left lateral position, eleven hours after the accident. The foetus, placenta and membranes were removed, the uterus stitched up with two layers of No. 3 chromicized catgut, the abdominal cavity swabbed out, and the abdomen closed. Nineteen months later the patient became pregnant and was delivered after a normal labour at full time. The placenta was somewhat adherent

and she had fairly severe hæmorrhage after its removal. This was controlled by an injection of pituitary. Otherwise the puerperium was normal.

I believe this is the first case of normal labour following traumatic rupture of the uterus to be reported.

WOLING.

R. THORNE THORNE.

Reports of Societies.

CONGENITAL SYPHILIS.

THE discussion on congenital syphilis which was opened on February 25th in the Section for the Study of Disease in Children of the Royal Society of Medicine (BRITISH MEDICAL JOURNAL, March 5th, p. 342), was concluded at a further meeting on March 16th.

Dr. H. MORLEY FLETCHER remarked that in his experience of the last twenty-five years in London congenital syphilis appeared to have undergone considerable modification. The number of infants with frank manifestations of syphilis, such as skin eruptions and condylomata, was much less than it used to be, although this did not imply a diminution in case-frequency, only a change in type. He had not seen a single instance in which a positive Wassermann reaction had followed a prophylactic injection in a child, nor had he met a case with a positive reaction in the cerebro-spinal fluid in a child when the blood reaction was not also positive. In syphilitic children, especially during the first few years of life, the resistance to infection generally was lowered. The association of congenital syphilis with tuberculosis was not sufficiently appreciated. Lymphadenitis was the form of tuberculous disease he had seen most frequently in syphilitic children. In tuberculous cases in which there was any family history of syphilis, or in which any stigmata were present, the Wassermann test should be done. One of the most striking features of syphilis was the widespread nature of the lesions it caused. He dealt in particular with the morbid changes in syphilitic kidney, which in the stillborn foetus showed evidence of arrested development, and there was similar evidence in the infant, together with the beginning of sclerosis, which became more diffuse as the age advanced. Syphilis should always be borne in mind in cases of renal disease in children. He believed that larger doses of mercury, of which children were tolerant, should be given.

Dr. JOHN ADAMS gave some further particulars of his work in the clinic at Thavies Inn, to which many references have been made in this JOURNAL. During the last year, of the 37 pregnant women admitted with syphilis and treated, all gave birth to living children, 36 of whom showed a negative Wassermann reaction and one a positive. The treatment of congenital syphilis in older children was very unsatisfactory, but ante-natal and post-natal treatment was most encouraging. He had not seen a case of secondary syphilis in a child during the last two years in the clinic over which he presided, and if there were no manifestations of syphilis within the first twelve months one might be confident that there would be none afterwards. When a woman of seven months' pregnancy contracted syphilis, the child appeared to be born healthy without ante-natal treatment, and to remain negative to the Wassermann test, doubtless owing, as Dr. Amand Routh had suggested, to some ferment in the placenta which had the power of intercepting and destroying the syphilitic virus. Dr. Adams urged that lying-in centres should be established in every large town, with medical officers specially appointed to look after them.

Dr. R. C. JEWESBURY gave an account of the clinic at St. Thomas's Hospital, which was started rather more than a year ago for the treatment of children suffering from congenital syphilis. He reproduced a number of family histories, including the regular type—that is, a number of miscarriages followed by live births, and ultimately, perhaps, by the birth of healthy children—and the irregular types, which followed no such progress. These two types were about equal in frequency. In a number of cases—about 10 per cent. of those investigated—in which the mother was syphilitic before the birth of the child, the child was born apparently healthy and continued without the appearance of any signs which called for attention until perhaps the tenth year or later, when symptoms—chiefly mental, such as dullness—developed; these cases

were the hardest of all to treat. The total number of cases treated in the year was 145. The mothers of all these children were known to be syphilitic, but in 9 cases the infection occurred after the birth of the child, so that the syphilis in the child was acquired. Only 47 of the mothers had had any treatment before or during pregnancy, and in only 39 of these cases was this treatment at all systematic. The results were as follows:

	Mothers Untreated.	Mothers Treated.
Cases investigated	77	39
Total pregnancies	322	53
Miscarriages or stillbirths	97	1
Infants died	73	5
Children still alive at time of investigation	152	46
Mortality of children born alive	32.4%	11.5%

Mr. J. E. R. McDONAGH said that at the Lock Hospital it had been found that if a woman had contracted syphilis up to the fifth month of pregnancy the chances were that the child would be born syphilitic; if in the sixth or seventh month, the chances were about equally divided; and if in the eighth or ninth month, the chances were that the child would be born not syphilitic. Many of the children in this last category, however, acquired syphilis after birth as a result of suckling, and he thought it well to assume that every child of a syphilitic mother was syphilitic. He did not look forward hopefully to the results of subsequent pregnancies in the case of women who had been treated during one pregnancy. Once a woman was syphilitic, the chances were, however much treatment she might receive, that she would be syphilitic in subsequent pregnancies.

Mr. H. NAME gave some particulars of the results of the treatment of interstitial keratitis with arsenic in addition to ordinary mercury. He spoke on the basis of 24 cases carefully tested at the London Hospital. It was doubtful whether, if a patient came up for treatment before both eyes were affected, the treatment could prevent the infection of the second eye. In five of his cases the second eye became infected after treatment. He thought it reasonable to assume that arsenical preparations, if given in large doses, could prevent complications such as choroido-retinitis, seeing that the choroid was a vascular structure. His doses were generally 50 per cent. above the recognized doses for the size and weight of the child. He believed that when the interstitial keratitis was actually established the treatment was of benefit in improving the visual acuity in a very large proportion of cases, and he was sure that prophylactic treatment would be of much benefit in preventing interstitial keratitis.

Mr. A. T. PITTS, discussing the teeth in congenital syphilis, mentioned that out of some thousands of cases he had never seen Hutchinson's teeth in the milk dentition, though cases had been recorded, and there was no reason why, if the infection began early enough in the foetus, these should not occur. He suggested *a priori* that syphilis should be regarded as one of the causes of hyperplasia of the milk teeth, and any well-marked cases should arouse suspicion sufficient to warrant further investigation.

Dr. RONALD CARTER, who spoke from the general practitioner's point of view, said that there was a good deal of nervousness and jumpiness with regard to congenital syphilis. His own strong impression, from twenty-five years of general practice, was that congenital syphilis was comparatively rare, but the statistics lately given by Dr. Helen Campbell of Bradford caused some amazement and misgiving. He did not think that such statistics should be accepted unquestioningly.

Dr. F. LANGMEAD, the President of the Section, in reviewing the discussion, said that its most important feature was the general consensus of opinion as to the extreme value of the treatment of pregnant syphilitic women.

Sir HUMPHRY ROLLESTON, in replying, said that the change in the type of congenital syphilis, to which Dr. Morley Fletcher had drawn attention, was possibly due to some alteration in the strain of the spirochæte, which, instead of being attracted towards the skin, sought the viscera and nervous system. One interesting fact brought

out in the discussion was that acute infections might stir up syphilis in a frank form. With regard to treatment, he thought that they had perhaps been too much afraid to push mercury to the extent that was desirable. He congratulated Dr. Adams and other workers in ante natal and post natal treatment on their results.

INSTRUMENTAL ABORTION.

A MEETING of the West London Medico Chirurgical Society was held at the West London Hospital on March 4th, with the President, Dr. F. J. MCCANN, in the chair. A paper was read by Dr. BERNARD H. SPILSBURY on instrumental abortion. Observing that abortion was a practice by no means confined to civilized communities, he instanced some of the crude methods in use amongst primitive races—for example, pummeling the abdomen with stones. For the production of abortion the most effective methods were those in which violence or other physical agents were applied directly to the uterus. Success depended on the amount of the local disturbance and to some extent on the readiness of the uterine reaction—a factor which varied in different individuals. The following were some of the commoner methods used:

1. Passing an instrument into the cervical canal or into the body of the uterus. In self attempted abortion the favourite instrument was a hat pin, crochet hook, or a skewer. Skilled abortionists resorted to more suitable instruments, such as catheters. Without the requisite anatomical knowledge a woman was most unlikely to pass an instrument into her own uterus unless prolapse was present.
2. Intravaginal injections of various fluids.
3. Intracervical injections of fluids, of which soap solution was a favourite. Even scalding water had been used.
4. Blowing air through a catheter passed into the uterus.
5. Manipulation of the external os uteri with the hand.
6. Packing the vagina.
7. Abdominal massage of the uterus.
8. Local application of electricity.
9. Dilatation of cervix and immediate removal of the products of conception—chiefly employed by medical practitioners.

The dangers of instrumental abortion were three—infection, haemorrhage, and shock. Infection was favoured by the large raw surface in the uterus and the proximity of large blood vessels to the placental site. Streptococci and the colon bacillus were the most frequent infecting agents. In fatal cases the course of infection varied greatly. At the one extreme was a rapidly fatal septicaemia with little or no local suppuration, and at the other was a prolonged septicaemia ending in pyaemia. Septic pulmonary infarcts were common. Massive embolism of the pulmonary artery might occur. Haemorrhage alone was occasionally responsible for death when the placental site was damaged or the uterus perforated, but it was more frequently associated with septic infection in fatal cases. Shock often occurred at the moment of passage of an instrument into the uterus and was usually transient, but occasionally instant death occurred. This might also result from the injection of fluid into the uterus.

The President referred particularly to treatment of cases of attempted abortion. Treatment must be prompt and first directed to a thorough cleansing of the whole genital passages. If this proved ineffective there should be no hesitation in opening the abdomen and if necessary removing the uterus.

Dr. LATHORP SMITH endorsed the President's statements, and pointed out that the doctor's first duty was to save the patient, and not to act as a detective. It was always wise in these cases to call in the aid of another practitioner both for his medical assistance and to avoid any appearance of secrecy. After cleansing the passages he advised the free use of powdered boric acid in the vagina.

Dr. W. H. WILLCOX congratulated Dr. Spilsbury on his comprehensive paper, and referred to Dr. Spilsbury's unrivalled experience of these cases during the past fifteen years. He said that frequently instrumental abortion was aided by ecbotic drugs given either before or after the mechanical interference. He was glad that two important points had been emphasized. The first was that the mere passage of an instrument into the pregnant uterus might cause sudden death; several instances of this had occurred in recent years. The second point was the extreme rapidity with which septicaemia often occurred, since in many instances septic organisms were directly introduced into the peritoneal cavity.

Dr. A. KNYVETT GORDON said that from his experience in the treatment of many cases of puerperal septicaemia he had come to regard the administration of large doses of antistreptococcal or anticolonic bacillus serum (according to the bacteriology of the case) as the most valuable constitutional remedy we had. At least 100 c.cm. should be given in two pints of saline into the subcutaneous tissues. He strongly deprecated the use of vaccines in acute cases; it was wrong in theory and disastrous in practice.

Dr. J. A. MANSELL MOLLIN agreed with what had been said regarding early treatment. Free drainage of the infected uterus was imperative, with laparotomy if necessary. Dr. F. G. LLOYD said that these cases were always unsatisfactory from the practitioner's standpoint. He strongly advocated sharing the responsibility with another practitioner in suspected cases of criminal abortion. Any deposition made by the patient could only be taken as evidence if the patient fully appreciated that she was beyond hope of recovery.

HAEMOCHROMATOSIS AND BRONZED DIABETES.

A MEETING of the Royal Medico Chirurgical Society of Glasgow was held on February 18th, when Professor ROBERT MUIR gave a lecture and microscopic demonstration on haemochromatosis and bronzed diabetes. He pointed out that the essential pathological feature was the deposit of iron containing pigment in great amount and in unusual positions, this resulting in haemochromatosis. Diabetes resulted only when the lesion in the pancreas was of sufficient degree, there being cirrhosis in this organ as well as in the liver. Two cases were described in which both bronzing of the skin and diabetes were present, and reference was made to the estimations of iron carried out with Professor Shaw Dunn in one of these. An account was given of two cases at an early stage of the affection, and from these the inference was drawn that the earliest lesions were cirrhosis of the liver and pancreas, with deposits of haemosiderin in these organs and in the retro-peritoneal lymphatic glands. In the pancreas the changes occurred at an earlier period in the secreting epithelium than in the islands of Langerhans, but the results did not warrant a conclusion as to the relation of the lesions in these structures to the onset of diabetes. The lecturer contrasted the deposits of pigment with those occurring from abnormal haemolysis, and pointed out that they differed both in amount and in distribution, those in haemochromatosis being much greater and occurring in sites, such as thyroid, heart muscle, skin and stomach, in which haemosiderin resulting from haemolysis did not occur. From these facts and from the fact that in haemochromatosis there was no evidence of increased blood destruction or regeneration, it was not justifiable to conclude that the iron pigment was actually derived from haemoglobin. There might be an inability to use up again the iron derived from normal haemolysis, but in this case the peculiar distribution of the pigment could not be explained. The essential factor in haemochromatosis appeared to be a special affinity of the tissues and organs for iron, and the source of the stored iron must ultimately be the iron in the food, but whether or not it passed through the form of haemoglobin was not certain. The cirrhosis of the liver, and possibly of the pancreas, seemed in some way to be related to this abnormal metabolism of iron, but there must be some special factor, as in most cases of cirrhosis of the liver the accumulation of pigment was absent. The accumulation of iron must go on for a long period of time, sometimes for two or three years, even if all the iron in the food were retained.

DIATHERMY FOR INOPERABLE GROWTHS.

A MEETING was held at Liverpool of the Liverpool Medical Institution, conjointly with the Manchester Medical Society, on March 3rd, with Dr. J. E. GEMMELL in the chair. Sir WILLIAM MILLIGAN read a paper on the treatment of inoperable malignant growths of the pharyngeal and epiglaryngeal regions by means of diathermy and radio-diathermy. He pointed out the type of case suitable for diathermy treatment and described the

rationale of the treatment. In cases in which diathermy was done close to large blood vessels great care had to be taken, as otherwise there was a risk of sloughing of arterial walls and severe secondary haemorrhage. In many cases it was advisable to tie the main blood vessels leading to the affected regions. Diathermy treatment had the advantage of sterilizing the tissues, blocking the lymphatics and small blood vessels, and of readily destroying malignant cells owing to their having in all probability a lower vitality than normal cells. Where the growth to be treated was situated in the immediate neighbourhood of the larynx, it was advisable to perform a preliminary tracheotomy. In small growths the best results appeared to follow the use of a current of from 500 to 900 milliamperes, but in large growths 1 to 2 amperes were necessary. Where there was much necrotic tissue it was a good plan to perform a preliminary scraping, great care being taken, however, to avoid any bleeding as far as possible. The pain produced was, as a rule, not great until about the eighth or tenth day, when it was considerable owing to the separation of the slough and the formation of a raw granulating surface. The presence of glands did not negative diathermy operations, and glands might be treated either by diathermy itself or by intensive x-ray treatment. Where intensive x-ray treatment was used it was advisable to desensitize the skin either by the application of pressure or by the subcutaneous injection of salt solution.

The advantages of diathermy were:

1. It might be employed when ordinary surgical procedures were impracticable.
2. It did not produce much, if any, shock.
3. With reasonable care it was a bloodless procedure.
4. It had the merit of sterilizing the tissues, blocking vascular and lymphatic vessels, and preventing the dissemination of the cancer cell.
5. It frequently afforded relief from painful symptoms and mechanical difficulties in cases surgically hopeless.
6. Septic and bronchopneumonia were much less frequent than after cutting operations.

Its disadvantages were:

1. It destroyed both healthy and diseased tissues.
2. The walls of adjacent blood vessels might become softened and secondary haemorrhage result.
3. Where the skin was involved keloid cicatrices might result.

He referred to a series of inoperable surgical cases where by means of diathermy life has been prolonged for from two and a half to three years with complete comfort.

Variations of the Normal Stomach.

Dr. A. E. BARGAY discussed the variations of the normal stomach. He maintained that the old anatomical pictures were caricatures, and that the distortions were due to the action of formalin or other preservatives, coupled with the effect of rigor mortis. Essentially the stomach was a living muscular tube whose very varied alterations in appearance were largely due to alterations in muscular tone. The tonic action was a function of the living tone, and could only be studied in life by means of roentgen rays. The main function of this tonic action was to stabilize the stomach so that it maintained the contents in tubular form in spite of gravity. When tone relaxed the contents descended to the lowest part of the stomach. He demonstrated models of normal empty and full stomachs, and also a series indicating the way in which its shape was changed by the alteration of posture. Tonic action was responsible for the maintenance of the shape of the normal stomach, and he insisted that transitory loss of tone and gastroptosis were simply variations of the normal. He then dealt with the musculature, and laid stress on the great importance of the innermost layer, the incomplete and powerful band of oblique fibres passing down on either side of the lesser curvature, and illustrated the band by a series of dissections by Jefferson. He pointed out that in atony this oblique band was apparently unaffected, while the rest of the muscle was thinned out. In gastroptosis, on the other hand, the oblique fibres were elongated proportionately with the other coats.

Professor E. S. REYNOLDS mentioned some points arising in connexion with vascular lesions of the brain, quoting illustrative cases. He referred particularly to meningeal haemorrhage occurring during birth, to emboli and their results, and compared these in their symptoms and course

with thrombi and haemorrhage. He alluded to the difficulty which often occurred in diagnosing whether a hemiplegia was due to thrombus or haemorrhage, and the consequent difficulty in treatment.

Sir WILLIAM THORBURN gave an account of cases of posterior rhizotomy and of drainage of the spinal theca. He related several personal cases in which the operation of rhizotomy had been performed for gastric crises, and analysed the published records. With regard to rhizotomy for pain, he indicated, again from personal cases, why in many instances relief was not to be anticipated, and why the results were less satisfactory than in gastric crises. He did not recommend Foerster's operation for spastic paraplegia. He then referred to cases resembling transverse myelitis, in which drainage of the theca spinalis was followed by rapid recovery. He recalled the earlier work of Horsley on so-called chronic spinal meningitis, and strongly urged the exploration of any doubtful cases of this type; in practised hands the operation of laminectomy was as safe and reliable as laparotomy.

THE CIRCULATION IN ACUTE INFECTION.

At a meeting of the London Association of the Medical Women's Federation held on March 8th, with Mrs. FLEMING, M.D., in the chair, Dr. ESTHER HARDING read a paper on the circulation during and after acute infection. She pointed out that this problem involved a discussion of the conditions not only of the heart and myocardium, but also of the blood vessels, the nervous mechanism—central or peripheral—controlling blood vessels, and of the blood, as all these divisions of the circulatory mechanism were affected, primarily or secondarily, in acute infections. Her data were gathered chiefly from a study of diphtheria and influenza, but probably similar effects could be demonstrated in many other diseases—for instance, acute rheumatism, typhoid fever, pneumonia, and cholera. Diphtheria was, she said, particularly suitable for studying circulatory changes, because in this disease they were well marked and the complications of pyrexia were practically absent. Observations on the specific gravity of the blood in toxæmic cases showed that the slight general oedema—so called "anasarca"—was accompanied by a definite increase in the fluid content of the blood, due to the loss of part of the fluid content, which led to a decreased volume of the blood in circulation. This fact suggested that the circulatory failure of diphtheria might be, in part at least, due to a condition resembling the oligæmic phenomenon described by Yandell Henderson in cases of shock. Recognizable dilatation of the heart was rare in fever hospitals, probably because of the complete rest enjoined on the patient, but very rapid dilatation might occur whenever exertion had been allowed at too early a stage of convalescence. Quickening of the heart, related either to myocardial insufficiency or to low peripheral blood pressure, occurred during most fevers. Slowing of the heart was the rule in certain fevers—for instance, typhoid fever—and it was very frequent in severe diphtheria and was usually of very grave significance. Of abnormal rhythms curtailed diastole frequently accompanied increased rate, sinus arrhythmia tended to disappear as the heart quickened. Sir James Mackenzie taught that its reappearance might be taken as a sign of the return to normal, but Dr. Harding found an irregularity which she had taken to be sinus arrhythmia practically always present in cases of diphtheria with slowed heart rate. Sir James Mackenzie, to whom she submitted tracings of the condition, suggested however that the condition was not of true sinus type and might be peculiar to diphtheria.

The late effects of infection might be grouped under two headings: myocardial weakness, and weakness of peripheral circulation, which might or might not be vasomotor in origin. The differential diagnosis between the two types was important from the point of view of treatment. In both the patient complained of feeling slack, there was some breathlessness and palpitation, fatigue from mental exertion, and irritability; in both there was an excitable heart, shortened diastole and poor exercise response. In the myocardial group the patient was at his best in the morning after a night's rest, and got more and more tired as the day went on; in the peripheral weakness group the patient was tired in the early part of the day,

but improved with exercise. The myocardial group were breathless all the time and the breathlessness was of the anaemic type, with curtailed expiratory pause; the peripheral type were breathless only after exertion. For the first group prolonged rest was necessary, and bromides and digitalis were very useful; in the second type strychnine, cold baths, and adrenalin by the mouth first thing in the morning were often very helpful. It was important, also, in dealing with long-continued debility following acute infection not to forget the possibility of functional weakness dependent on a psychological cause.

Rebicus.

DISEASES OF THROAT, NOSE AND EAR.

THE task of producing a textbook on *Diseases of the Throat, Nose and Ear*¹ within a volume of reasonable size has severely taxed the powers of Dr. DAN MCKENZIE, and had the author concentrated himself on one or other of these subjects we believe that he would have succeeded in writing a book of more permanent value. While Dr. McKenzie writes with a freshness of style and originality of thought which makes the book eminently readable, he shows rather too pronounced a tendency to break away from accepted teaching. This would no doubt be admirable and justifiable in a monograph on some special subject, but in a textbook it is apt to give the student somewhat one-sided views. References are not given, though numerous writers are quoted. The author, however, does not always show a correct sense of proportion in giving prominence to the opinions quoted; sometimes he attaches great weight to a minor point, while at others he seems scarcely to give credit where credit is due. As an instance of this neither Sluder nor Whillis and Pybus are mentioned in connexion with tonsillectomy. Much as he has undertaken within the precise limits of the title, the writer has gone still further and introduced material not strictly cognate. A striking example of this is the part dealing with diseases of the thyroid gland, which is introduced in the chapter on diseases of the trachea. The thyroid gland, of course, falls to some extent within the province of the laryngologist as well as of the general surgeon, and the writer rather deprecatingly begins his description with the words "Only those diseases of the thyroid gland will be touched upon which have particular bearing upon laryngology." Yet he touches upon almost all of them. Thus exophthalmic goitre is included, though it presents a problem of general medicine, and has no special connexion with laryngology, as malignant disease may have. The author has devoted much space to operative surgery; this is, on the whole, very helpful, and brings the subject well abreast of the times, though here and there a somewhat unexpected vein of pessimism shows itself. In the section on the ear there are certain statements regarding the intracranial complications of middle-ear disease which demand notice. The author states that in uncomplicated cases of lateral sinus thrombosis optic neuritis is absent. Presumably he means in cases in which lateral sinus thrombosis is the only complication, but in actual fact optic neuritis is not infrequent in such cases apart from other complications. Again, ligation of the jugular vein in every case is strongly advised by Dr. McKenzie. The indications, however, both for and against this procedure were laid down definitely by Ballance many years ago, and nothing has since been added. In dealing with abscesses of the brain, whether cerebral or cerebellar, the author advises a preliminary lumbar puncture; but this is a procedure which has been condemned by good authorities, since the sudden alteration in intracranial pressure may cause the abscess to burst. Finally, it is strange that a description of otosclerosis should contain no reference to the classical researches of Albert Gray, although other authorities are mentioned. The book affords a fair and comprehensive survey of the latest work in the subjects indicated; its value is to be found in its breadth of outlook, while such defects as we have ventured to indicate seem to arise from the author having attempted to cast his net too wide.

Such matters will readily lend themselves to correction in a future edition. Dr. McKenzie has made a valuable contribution to laryngology and otology by treating his subject in an unconventional manner; such a book has the merit of stimulating the reader to think for himself.

The fact that a third edition of Dr. ROSS HALL SKILLER'S book on the *Accessory Sinuses of the Nose*² has already been called for is striking evidence of its popularity, for the previous editions were produced as recently as 1913 and 1916. We venture to say that the author has well merited the success his volume has achieved. In all essentials, both in form and material, the book is unaltered from the previous editions, but the opportunity has been taken of introducing such additional information as was derived from experience in the war. Amongst other things it is interesting to note that the author attributes the comparative rarity of wounds of the frontal sinus, in comparison to those of the antrum of Highmore, to the use of steel helmets. In this edition there is an account of Mosher's method of exenteration of the ethmoid capsule, illustrated by an excellent series of drawings. Another interesting, though minor, addition is a short account of the experiments of Caldera, which prove that inhaled medicaments reach the mucosa of the sinuses. These naturally did not appear in the first edition. The book remains and is likely long to remain not only the most exhaustive and accurate exposition of the subject, but also one to which it is natural to turn in any case of doubt or difficulty for sound and practical advice. In this respect, the manner in which the vexed question of the treatment of the diseases of the frontal sinuses is approached displays the care and judgement of the writer, and the advice given is a model of wisdom and good counsel. No laryngologist can afford to be without the help of this book, and the only criticism we have to offer which bears on it particularly as a work of reference is that it deserves a better index.

THE SYMPATHETIC AND THE ENDOCRINE GLANDS.

THE ninth volume in order and the eighth to appear of the thirty-two promised parts of the *Traité de pathologie médicale et de thérapeutique appliquée*, edited by Emile Sergeant, Ribadeau-Dumas and Babonneix, is that on *Sympathique et glandes endocrines*, by LUREBOULET, HARVIER, CARRION and GUILLAUME.³ Although clearly it is impossible to study one apart from the other, the idea of combining the accounts of the sympathetic with those of the glands of internal secretion in the same volume is both novel and convenient. The endocrine glands are first dealt with, and then, in the remaining third of the volume, the sympathetic system is described by A. C. Guillaume, who devotes sixty pages to the anatomy and physiology, and by P. Harvier, who summarizes the pathological aspects. The concluding chapter, on the therapeutical uses of the endocrine glands, has been entrusted to Carrion, who points out that there does not appear to be any general contraindications to the administration of organic extracts, and that so long as they are given by the mouth the question of anaphylaxis may be neglected. But in the case of each therapeutic product there are, of course, points of importance that must be taken into consideration. Formerly, when disturbances of a single gland, such as the thyroid in myxoedema or the adrenals in Addison's disease, formed the guiding principle in our conception of endocrine disorders, the problems of etiology and treatment were comparatively simple; but now that the functional correlation and interdependence of the glands of internal secretion have been established by experimental, physiological, and anatomical research, the more difficult subject of the pluriglandular syndromes—a term introduced by Claude and Gougeot in 1907—must be faced. As the physiology and anatomy of the endocrine glands do not

¹ *Diseases of the Throat, Nose and Ear*. By DAN MCKENZIE, M.D., F.R.C.S.E. London: W. Heinemann (Medical Books), Ltd. 1920. (Hr., 8vo, pp. 661; 199 figures, 2 plates, 42s. net.)

² *The Catarrhal and Suppurative Diseases of the Accessory Sinuses of the Nose*. By R. H. SKILLER, M.D. Third edition, thoroughly revised and enlarged. Philadelphia and London: J. B. Lippincott Co. 1920. (Med. 8vo, pp. 442; 247 figures, 5 plates, 30s. net.)

³ *Sympathique et glandes endocrines*.

justify a classification of pluriglandular disorders, a clinical method has been adopted, and on these lines three main groups are described: (1) Primary change in one gland with secondary disorders in one or more—for example, Graves's disease with ovarian insufficiency and amenorrhoea; (2) the association of two uniglandular syndromes—for example, myxoedema with acromegaly; (3) the association of several uniglandular syndromes without well-marked predominance of any one. The most potent causes of pluriglandular syndromes are syphilis, whether congenital or acquired, and tuberculosis, and one of the commonest forms is that due to insufficiency of the thyroid, testis, and adrenal.

In his general introduction Lereboullet, referring to the treatment of pluriglandular syndromes, states that in some cases the extracts of the affected glands should be given successively, whereas in other instances they should be given simultaneously; but his favourite preparation is a cachet containing extracts of thyroid, pituitary, ovary, and adrenal, and he finds that thyroid extract is better borne when combined with adrenalin or pituitary extract than alone. The whole subject matter is clearly and attractively described, and we get a good picture of contemporary French opinion.

ANXIETY HYSTERIA.

THE unpretentious little volume on *Anxiety Hysteria*,⁴ of which Dr. C. H. L. RIXON and Dr. D. MATTHEW are jointly the authors, is one which it is definitely a pleasure to read. Many books have been written on the war neuroses, but we do not recall one which would appear so exactly to meet the needs of the busy practitioner as this. The subject is presented in clear, precise, and non-technical language. The psychology is sound though elementary, and it suffices to give the practitioner an understanding of the symptoms which are peculiar to these nervous cases. The chapter on treatment is practical and detailed, and it is evident that the authors' views are based upon a wide experience. The therapeutic measure utilized more especially is that of "free association," but the use of the term psycho-analysis is avoided on grounds which appear to be sound. This term has now come to be regarded as implying adherence to a particular view as to the origin of the neuroses, and in its place "Mental Exploration" is employed as a term which does no more than describe the method of treatment adopted.

Colonel Sir A. Lisle Webb, Director-General of Medical Services, Ministry of Pensions, contributes a sympathetic foreword to this volume, and with his views as to its value to those who are brought into contact with the problems of functional nervous disorder we are in complete agreement.

THE PHYSICAL BASIS OF HEREDITY.

JUST as the publication of the *Origin of Species* gave an enormous impetus to research in comparative anatomy, so the experimental work of Grigor Mendel has created an army of workers who have turned their attention to the problems of heredity. The results of their investigations have yielded a vast output of literature. One of the most recent books, dealing in a more or less comprehensive manner with the results so far obtained, is that by Professor T. H. MORGAN of Columbia University, entitled *The Physical Basis of Heredity*.⁵ It is one of the series of monographs on experimental biology now being published in America.

The subject of heredity is one of the utmost importance not merely from the purely scientific point of view, but also from its bearings on the health and social conditions of the community. Mendel obtained his facts by the careful record of results of experimental breeding and crossing of plants. For some years past this line of attack has been, and is still being, carried on and extended. This further work has, in the main, confirmed Mendel's conclusions. It was soon found, however, that

breeding experiments alone, whether in plants or animals, afforded no explanation of the facts. Consequently, a solution of the problem was sought by cytological investigation. This has yielded many facts and much theory. Professor Morgan has attempted to give a summary of both in his book, and has added a bibliography which extends to twenty-seven pages, but is yet by no means exhaustive.

Cytologists regard the chromosomes as the important if not the sole carriers of heritable characters. Recent cytological researches have taught us, however, much with regard to protoplasmic inclusions and a knowledge of their behaviour in cell division. These, together with observations on maternal inheritance, afford much room for speculation as to the part played by the cytoplasm, if any, in the transmission of characters from parent to offspring. Several chapters are devoted to a discussion of these problems and to the observed facts upon which it depends.

Plough's interesting and important experiments on the influence of temperature on chromosomal "crossing over" are recounted, and in the author's opinion can be adduced as evidence against the "reduplication theory" of Bateson and Punnett.

It is impossible in a short space to deal adequately with the many aspects of so wide a field as are dealt with in the volume under consideration. The author's general attitude towards the problems of inheritance is set forth in the introduction, and he there states that one of the objects he had in view in writing the book was to show that objections to "particulate inheritance" have no real foundations in fact. Nevertheless, however intimate may be our knowledge as to the behaviour of the chromosomes during resting and mitotic phases, a perusal of the book shows that we are still a very long way from understanding the causation of such behaviour. The field for speculation seems almost illimitable.

Professor Morgan's work in this and in other fields is well known and appreciated by all biologists. Any book of which he is the author is sure to arouse interest. In this instance he has succeeded in placing before us a good account of the present position of the subject. He may well be congratulated on the result. It is "stiff reading," but the subject matter requires "stiff thinking."

THORPE'S DICTIONARY OF APPLIED CHEMISTRY.

THE interval between the publication of the last edition of Sir EDWARD THORPE's *Dictionary of Applied Chemistry*⁶ and its immediate predecessor was twenty-two years. In the preface to the new edition, the first volume of which was published a few weeks ago, the editor considers it necessary to apologize for the fact that, owing to circumstances arising out of the war, it has not appeared earlier; yet the interval on this occasion is only nine years. We have heard much of the influence of applied chemistry on the operations of the war, but Sir Edward Thorpe maintains that it is equally true that the war exercised a great influence on applied chemistry, both in this country and abroad, leading to an enormous expansion, more or less permanent, of certain branches. New products have been made, new processes devised, and established methods improved and extended. The progress of manufacturing chemistry in this country and in other English-speaking countries has, he believes, been permanently affected for good. The entire work has been carefully revised, and for this purpose many new contributors have been found. The new edition, however, has one disadvantage—that it has been found necessary to increase the size. The last edition contained five volumes, its predecessor three; the new edition will contain at least six, possibly seven.

The first volume of the new edition carries the matter from A to C, the last article being a lengthy account of the uses of calcium and its salts. The article on alkaloïds is contributed jointly by Dr. George Barger, F.R.S., Professor of Chemistry in relation to Medicine in the University of Edinburgh, and Dr. F. L. Pyman, Professor of Technological Chemistry in the University of Manchester. Professor Barger has also written articles on several drugs.

⁶ *A Dictionary of Applied Chemistry*. By Sir Edward Thorpe, C.B., LL.D., F.R.S., assisted by eminent contributors. Vol. I. Revised and enlarged edition. London and New York: Longmans, Green and Co. 1921. (Med. 8vo, pp. 752 + x; illustrated. 60s. net.)

⁴ *Anxiety Hysteria. Modern Views on some Neuroses*. By C. H. L. Rixon, M.D., M.R.C.S., and D. Matthew, M.C., M.B., Ch.B.; with a foreword by Colonel Sir A. Lisle Webb, K.B.E., C.B., C.M.G. London: H. K. Lewis and Co., Ltd. 1920. (Crown 8vo, pp. 136; 8 illustrations 4s. 6d. net.)

⁵ *The Physical Basis of Heredity*. By Thomas Hunt Morgan, Professor of Experimental Biology, Columbia University. Philadelphia and London: J. B. Lippincott Co. 1920. (Demy 8vo, pp. 305; 117 figures. 10s. 6d. net.)

including that on acouitine and the acouite alkaloids, and on adrenaline. The latter contains an account of the physiological methods of estimating the substance and a list of substitutes. Professor Halliburton again contributes the articles on bile, blood, and bone. It has not been found necessary to make any considerable alterations in the article on bread, but it is noted that under war conditions arrangements were made in Germany to collect the germ of wheat from the mills and extract the 10 to 12 per cent. of oil which it contains, with the intention of using it for the production of margarine. The longest article in this volume is that on analysis, the first part written by Professor G. T. Morgan, of Birmingham, and the second, on electro-chemical analysis, by Dr. F. Mollwo Perkin.

Thorpe's Dictionary has long been an indispensable part of laboratory libraries, whether those of research institutes or of manufactories, and the new edition, judging by the first volume, will fully maintain its high reputation.

NOTES ON BOOKS.

MENTAL nurses will find in *Model Answers to Questions on Nursing*, by Mr. HECTOR MACPHAIL, a book which should prove of real assistance to them in preparing for their examinations. Many nurses with a good knowledge of their work have had little experience in putting their ideas on paper, and for such, a book of this kind is almost a necessity. Its answers contain a large amount of useful information which will serve to supplement and to express in a somewhat different form the contents of the ordinary nursing manuals. The answers are brief and to the point, and altogether as many as 240 questions are dealt with. The regulations for the nursing certificate of the Medico-Psychological Association have recently been altered, and, no doubt, Mr. Macphail will note this in any subsequent editions of his book. We observe in one question that manic-depressive insanity is spelt *maniac-depressive*. We fear it is not a misprint and suspect that some examiner must be blamed for this rather than Mr. Macphail himself.

Dr. C. B. BURR, an American psychiatrist, has revised his book entitled *Practical Psychology and Psychiatry*,⁸ the fifth edition of which has recently been published. It is written for the use of nurses and attendants who are taking a course in mental nursing. Both the theoretical and practical parts are clearly written, but we are of the opinion that the chapter on "Symbolism in sanity and insanity" is most unsuitable in a textbook designed for mental nurses. It is almost incredible that these crudely sexual details and vulgarisms should be recounted for the instruction of young, immature, and often poorly educated girls, and it is most difficult to find any possible value to nurses in the information thus conveyed.

Sarah Battle, who is still something of an authority, held that in square games (she meant whist) "all that is possible to be attained in card games is accomplished." At any rate, if for whist we substitute its grandchild, Royal Auction Bridge, a great many doctors will be found to endorse Mrs. Battle's opinion. It needed little observation during the war to discover the popularity of auction among members of the medical profession. In every officers' mess it beguiled the tedium of inactive times, at home and abroad; it was played in sun-scorched tents, and in waterlogged dug-outs by the light of candles that flickered with each bursting shell; and the medical officers who served afloat found it a solace on every one of the seven seas. We may therefore be excused for noticing very briefly two little treatises on this game of cards that have been sent to us for review. The more important of the two is perhaps the new edition of *Royal Auction Bridge*⁹ by the well known writer "Bascule," who now includes a chapter on Contract Bridge for those who agree with him that that is "the game of the future." In other respects it differs little from the first edition, which went through many impressions. The other work is a second edition of Colonel HINGLEY'S *Hints on Royal Auction Bridge*.¹⁰ This, in a conversational way, sets out to guide the player

through some of the difficulties of declaring a suit and playing a hand. The author's method of instruction may be found helpful: "The truth is, a fearful lot of rubbish is written about bridge; the subject is very soon exhausted, and all any author can do is to point out some rules for guidance, nothing more. Some people prefer the very safe game, and some the forward game." In fact, the game of bridge is very like the game of life, save that it has rules framed by the Card Committee of the Portland Club, with the co-operation of a representative of each of five other clubs.

Medical chess players, of whom we believe there are a good number, may be glad to know of a little book, *The Pocket Guide to the Chess Openings*,¹¹ by Messrs. GRIFFITH and WHITE, the joint authors of a more comprehensive work on the same subject. Here will be found a selection of openings illustrating methods of play in the early stages of the game, drawn mainly from the practice of masters of to-day. For the guidance of less experienced players a summary is given of the laws of chess, together with a short definition of terms, a statement of the relative value of pieces, an introductory chapter on general principles in tactics and strategy, and a page of useful maxims which the beginner might well commit to memory.

APPLIANCES AND PREPARATIONS.

A Standardized Reverdin Needle and Holder.

MR. VICTOR BONNEY (London, W.) writes: A drawback to all the present patterns of Reverdin's needle is that, as the needle is attached to the holder by a square fitment, it is impossible to standardize them so that any needle will fit any holder of the same type. This objection applies even to the otherwise ideal pattern designed by my late assistant, Mr. Arthur Woo. The Genito-urinary Company have therefore constructed for me a new pattern similar to the Woo pattern, but having a round fitment, so that every needle fits the holder without special adjustment, and when new ones are required it is not necessary to send the holder back to the makers to fit them. This is a great improvement, especially for surgeons living in the country or abroad. The round fitment, moreover, has this further advantage that it allows of the needle being moved in the holder into any position the surgeon desires, so that, for instance, he can adjust it for passing it "back-handed" if he wishes to. The needle is held in the holder by a "locking lever," as in the Woo pattern, rendering changing of the needle a matter of a few seconds. The holder and needle can be obtained not only from the Genito-urinary Company who make it, but from Messrs. Allen and Hanbury as well.

Portable Manometer for Intrapericardial Pressure.

Dr. G. ARBOUR STEPHENS (Swansea) has devised a portable manometer for estimating the intrapericardial pressure *post mortem*. He finds it useful as a ready test (even without opening the chest) of heart failure as a cause of death, for in all such cases the fluid does not move in the glass tube—that is, the intrapericardial pressure is atmospheric, whereas when the heart is normal the fluid is drawn up towards the bent top, T, of the tube to which the rubber tube is attached—that is, there is a suction action due to the negative intrapericardial pressure which in health keeps the lubricating pericardial fluid at an equal thickness all round the heart. This fluid tends to vary in quantity and quality, and this variation has a marked effect on the movements of the heart. When the heart beats rapidly as the result of exercise, there is an increase of the area of cardiac dullness, due, in his opinion, to an increased secretion of the pericardial fluid necessary for lubricating the more rapidly moving organ, and the distress experienced before second-wind is established is, he thinks, due to the process of producing the right amount of that lubrication. In those cases in which objection is raised to a *post-mortem* examination the aspirating needle, N, can be inserted at the inner end of the fourth left intercostal space, and passed directly downwards towards the heart and through the anterior portion of the pericardium.

THERAPEUTIC TENDENCIES.

BY
CHARLES WHITBY, M.D.,
BATH.

IN an old book given to me by a patient, *Culpeper's Last Legacy*, the sixth edition, dated 1680, that famous seventeenth-century practitioner has set forth his "Choicest Secrets" for the benefit of posterity. For the most part it is an olla podrida of prescriptions for ailments of every kind culled from various authorities, many of an outrageous, disgusting or obviously superstitious nature, and some frankly ludicrous. One of Culpeper's remedies for epistaxis is to "put a piece of hot hog's tard as it comes from the hog up the nose!" Another, derived from Mizaldus, is to write *consummatus est* on the patient's forehead with his own blood. "If any be troubled with stomach worms," observes our good Nicholas, "let him hold a piece of a honey-comb in his mouth, and the worms will come out to the honey."

Still, Nicholas was no quack; no fool, either. Many of his suggestions are quite sound. He was, of course, a famous herbalist; he was also an anatomist, who made his own animal dissections, and had no scruples about giving Galen the lie direct when he found his descriptions inaccurate. In this last book, having previously dealt with simples on the same lines, he devoted several chapters to a synopsis of the compound remedies in general use in his day—and some of them are still far from obsolete—in which these are methodically tabulated according to their supposed general or local effects.

At no period has the practice of medicine been wholly empirical; and it certainly was not so in Culpeper's time. Among the great array of his remedies, genuine or superstitious, no choice could be made without guiding principles of some sort. We find these clearly indicated in Part III of his *Last Legacy*, entitled "Aphorisms." From this it appears that all medicines may be classified as heating, cooling, drying or moistening in effect; and that each of these qualities may be subdivided into four degrees. For example, a fluid which by outward application caused burns or blisters would be called heating in the fourth degree, and as such unfit for internal administration. Pathological conditions are similarly classified as hot, cold, dry or moist; and the general principle seems to have been that the kind and degree of pathological deviation, local or general, was a guide to the appropriate remedy. Thus, a condition of heat and dryness of the second degree would indicate a remedy cooling and moistening in the same degree. A moist remedy would be one which caused a flux of any kind—a purgative, diuretic or diaphoretic; a dry one would be a local or general astringent.

In addition to this primary classification, remedies are grouped in accordance with their topical affinities—what we should call their organotropisms. Part IV of the *Last Legacy* is devoted to aphorisms intended to guide the physician in the choice of drugs adapted to particular organs—for example, "cephalicks," "pectorals," "cordials" (that is, cardiac remedies), "renals," "hystericals" (that is, uterine agents), and so forth. Culpeper attached some importance to odour as a guide to remedies, particularly for those classified as "cephalicks," most of which are of a pleasant and aromatic or else of a decidedly nauseous odour. He thought that there was a special relation between the brain and the uterus, the joints and the stomach, so that all are similarly affected by the same drugs. He attached some importance to the doctrine of "signatures," that "yellow purges choler, black melancholy, white flegm," and so forth. He was also a professed astrologer, who was careful to gather his herbs under favourable aspects. But his mysticism is tempered by common sense, just as his inert or crude drugs are prescribed with suitable adjuvants or correctives. Such, then, in brief outline, were Culpeper's guiding lights. It will be interesting to compare with them those which underlie distinctively modern methods.

Of these, let us consider first the group of remedies comprised under the term vaccine therapy, a method rescued from empiricism by Pasteur's epoch-making discovery of

the rôle of the yeast plant in fermentation, and Davaine's identification of the anthrax bacillus. Like all great discoveries, this was but the bringing into clear light of a principle already adumbrated in the consciousness of mankind. The practice of inoculation for small-pox was begun in the early part of the eighteenth century, the famous Lady Mary Wortley Montagu having played a pioneer part in its popularization. When, in 1798, Edward Jenner, after twenty-five years' research, published his *Inquiry into the Causes and Effects of the Variolæ Vaccinæ*, the cruder form of prophylaxis was for some of his medical opponents a lucrative speciality. Jenner himself was led to investigate the subject by his frequent failure to inoculate with small-pox those of his country patients who had suffered from "cow-pox," and the discovery of a vague opinion among dairy folk that this was a preventive. It is the great principle of attenuation which is the foundation stone of vaccine therapy; and this stone was laid by Edward Jenner. I have searched Culpeper's book in vain for any evidence of awareness among seventeenth-century practitioners of the true nature of infection. In a section devoted to the Pestilence, he goes out of his way to combat the exaggerated terror of the disease, which in his day too often deprived sufferers of the services, not only of their neighbours, but even of a physician. He himself attributed the disease to a corrupted and unwholesome air caused by a malign conjunction of the superior planets. It is interesting, however, to find among Culpeper's prescriptions one recommending drachm doses of the desiccated and pulverized liver of a rabid dog as a remedy for the bite of such a dog. Also, there seems to be an anticipation of modern surgery in the strong recommendation of a linen cloth soaked in lime-water, prepared by pouring boiling water on quicklime in a clean new earthen vessel, as a dressing for wounds and ulcers. "This water," says Culpeper, "draws out the corruption of putrified sores." Mizaldus extols it to the skies.

The Jennerian method—that is to say, the introduction of pathogenic organisms in a living although attenuated state into the circulation—is not, of course, obsolete, but is, I think, in a fair way to become so. The awkward consequences that sometimes follow vaccination are, no doubt, in the majority of cases due to septic complications, but there must always be an element of uncertainty as to the behaviour of a living virus when introduced into a human organism. The modern tendency in vaccine therapy—a tendency accelerated, if not initiated, by the researches of Ehrlich and Almroth Wright—is to transform a biological and empirical into a chemical and truly rational method. These two distinguished men have approached the problem of the treatment of infective maladies the one from the chemical, the other from the biological point of view. Ehrlich's famous side-chain theory was an extension to the biological sphere of a hypothesis derived from the study of complex organic molecules, and was utilized by its inventor in an attempt to evolve an improved method of chemical treatment. Wright's opsonin theory was based on observation of the phenomena of infective and counter-infective processes, and is the basis of modern vaccine therapy. Yet the common aim of both investigations tends to a similar goal. In his recent investigations Wright has been drawn to inquire into the possibility of immunization *in vitro*, and deems it possible, "not only to test the efficiency of vaccines on normal blood *in vitro*, but also to determine upon the patient's blood *in vitro* what vaccine and what dose of that vaccine would give the desired effect." This clearly would be a close approximation to the ideal pharmacological method, especially in view of the fact that vaccines tend to conform to the chemical type of remedy, as isolated toxins of presumably definite and ascertainable composition. The term chemio-therapy calls to mind Ehrlich's epoch-making discovery of salvarsan (dioxidiamidoarsenobenzol dichlorhydrate), but the objective of his *therapia sterilisans* is, of course, achieved in a different way. With vaccines it is always an active immunity, due to exploitation of the latent phylactic resources of the patient, that is aimed at. Salvarsan is, by reason of its direct attack upon the constituents at once the strength and weakness of the method: on the one hand, the benefit is prompt and independent of the constitutional response of the patient; on the other hand, it is a merely quantitative effect, the

CURRENT NOTES.

Pay of the R.A.M.C.

THE Naval and Military Committee of the British Medical Association has had under consideration the question of pay and retired pay in the Royal Army Medical Corps. The revised scale of pay, published on September 13th, 1919, was not entirely satisfactory. The most notable anomaly which it contained was that concerning the retired pay of majors, who under the new scale actually received less money than they did before. The Association at once called attention to this point, and it has been remedied. The Committee is of opinion that the amended scale of pay and retired pay which was issued on October 9th, 1920, and published in the *BRITISH MEDICAL JOURNAL*, October 16th, is a fair scale, and compares favourably with those of other services. There are, however, several points which need adjustment, such as the absence of any provision for an increase in the pay of majors between fifteen years' service and the date of their promotion to lieutenant-colonel. There is also the case of the Director-General, A.M.S., who receives considerably less emoluments than any other officer holding a lieutenant-general's appointment, and, being on consolidated pay, is at a further disadvantage by reason of income tax. These matters will receive the attention of the Naval and Military Committee.

Refusal of a Medical Certificate on Behalf of a Jurywoman.

Recently the Under Sheriff of Middlesex declined to accept a certificate which stated that a certain lady on account of a recent operation for appendicitis was unable to serve upon a jury at the Middlesex Assizes. A certificate was sent in accordance with a notice on the summons which stated that

"Application for exemption from attendances at jury... must reach the Summoning Officer within three days of the receipt of this summons supported by medical certificate or otherwise that you are or will be unable to serve."

The Under Sheriff wrote stating that he was unable to excuse the patient, and must ask her to attend. Not having attended she was afterwards informed that she had been fined £2 2s. for non-attendance. The medical practitioner asked for the advice of the British Medical Association, and was told that if the patient was prepared to fight the case out she ought to write to the authorities and tell them that she did not intend to pay the fine and would be prepared to take the consequences, when the doctor would be able to attend the court and state his views on the injustice of the whole procedure. The practitioner was strongly advised to press this case as a test case, and was offered any help the Association could give him. He has since reported that the patient adopted the suggestion

made to her, and received, first, an apologetic explanation suggesting that someone had exceeded his authority, and, later, a notice that the fine had been remitted.

Wellhouse Hospital, Barnet.

The Wellhouse Hospital, Barnet, is a Poor Law infirmary with 204 beds, under the control of the board of guardians of the Barnet Union. The British Medical Association has had brought to its notice arrangements which have been made by the Barnet guardians whereby separate accommodation will be provided in the Wellhouse Hospital for persons who cannot secure admission to the voluntary hospitals, and are able to pay for medical care, treatment, and nursing. The local medical profession, which had not been consulted at all in the matter, held a meeting on January 19th, when a resolution was passed maintaining that the practitioners in the Barnet rural area should be allowed the right of entry into the Wellhouse Hospital to attend their own patients sent in by them. This was forwarded with a covering letter to the guardians, who, however, replied that they were unable at present to entertain any proposal to interfere with the existing arrangements, and indicating that the scheme in question had received the sanction of the Ministry of Health. The British Medical Association then approached the Ministry of Health in this matter, and the Deputy Medical Secretary, in the course of a letter, wrote as follows:

"Knowing how firmly the Minister believes in the advisability of consultation, both centrally and locally, in any new development of this kind, the Association is surprised at being informed that the new arrangements at the Wellhouse Hospital have received the sanction of the Minister of Health. Any new proposals for the medical service of the community are not likely to meet with much success if at the outset they are framed so as to excite hostility in the minds of the local medical profession, for, after all, the health services of this country cannot be satisfactory unless the hearty co-operation of the medical profession is assured. I should be glad to know, as soon as possible, whether or not the Minister has sanctioned the proposed arrangements at the Wellhouse Hospital, and whether or not he suggested that the local profession should be consulted before the scheme was finally settled. If the Minister has given his sanction I would most respectfully request that he suggests to the Barnet guardians the advisability of consulting the local profession before the schemes are actually put into operation."

The reply to this letter stated that the Ministry of Health had not been consulted in regard to the scheme of the board of guardians concerned. Inquiries have, however, been made, and the following letter has been addressed by the Ministry to the guardians of the Barnet Union:

"I am directed by the Minister of Health to state that he has been informed that the guardians of the Barnet Union have in contemplation a scheme for admitting persons other than sick poor to the Wellhouse Hospital. Such a scheme appears to the Minister to raise very important principles, medical and other, and he would be glad to receive as early as possible a full statement of the exact nature of the proposals, and what steps, if any, have been taken towards putting them into operation."

The matter is being considered by the Hospitals Committee of the Association at its meeting this week.

DANGEROUS DRUGS REGULATIONS.

The following is a summary of the evidence given on March 22nd before the Home Office Committee on Dangerous Drugs by Dr. J. W. Bone and Dr. Alfred Cox, on behalf of the British Medical Association:

1. The Association understands that the Committee is in possession of the correspondence which has passed between the Association and the Home Office in respect to the Draft Regulations. It is proposed, therefore, to take the detailed consideration of the Regulations up at the point where it was left by the letter from the Home Office of February 15th, on the assumption that the alterations in the Regulations promised by the Home Office will be made.

2. But before dealing with any details of the Regulations the Association desires to emphasize the statement made in the first paragraph of its Memorandum of February 3rd—namely, that it is "aware of the public danger arising from the improper use of the drugs . . . and recognizes that in consequence, medical practitioners must submit to the imposition of certain restraints in prescribing, compounding, dispensing and administering these drugs, and of certain clerical duties in recording their transactions in them." The Association, speaking on behalf of a very considerable section of the medical profession, trusts that before placing on the profession such restraints and clerical duties the Committee will satisfy itself that they are necessary, will carry out the objects of the Opium Convention, and are not merely being imposed on doctors because it is felt that as regulations must be imposed on some distributors they must be imposed on all.

3. Clause 7 of the Dangerous Drugs Act, 1920, says that provision may be made for, *inter alia*, regulating the issue of prescriptions and the dispensing of the drugs by medical practitioners "for the purpose of preventing the improper use of the drugs." The Association earnestly hopes that the Committee will satisfy itself that improper use of the drugs can rightfully be laid to the charge of the medical profession. So far as the British Medical Association has been able to ascertain there is no evidence that the medical profession has had any part in the illicit traffic in these drugs. Unless the Committee is satisfied that there is such evidence, the Association would urge that it will not countenance the idea of placing restrictions on a body of professional men to whom the lives and health of the community are entrusted, and who, therefore, may be assumed to be trustworthy as regards handling powerful and dangerous drugs. Their time ought not to be taken up in keeping records of small dealings in drugs, unless it can be proved that these records are essential.

4. The Association has carefully examined the draft Regulations as amended in accordance with the Home Office letter of February 15th. It would appear that the idea originally underlying the draft Regulations was that every distributor of the drugs shall keep a balance sheet of his dealings in them; that is to say, that every doctor, for example, shall keep records which would enable anyone investigating them to ascertain how much of each of the drugs has come into the doctor's possession and what has become of them. The Association agrees that if this could be done the information thus obtained would enable a close check to be kept on the distribution of these drugs.

5. But this idea, which presumably underlay the original draft Regulations, has been abandoned. The striking of a balance was never a possibility, even under the original draft. If Clauses 4 and 5 (as explained in the Home Office letter of February 15th) were not meant to apply to personal administration, and seeing also that no record need be kept of those quantities of the drugs which are used in making preparations of less percentage strength than those mentioned in the Act. Under the Regulations as amended the check kept on the distribution of those of "the drugs" which get into the possession of a medical practitioner is worthless.

6. The following example is taken from the practice of one of the witnesses (Dr. Bone) who is a partner in a large practice in Luton which dispenses for all its private patients:

In 1919 there were 25 buying transactions in the scheduled drugs which, aggregated, would appear as follows:

Opium.				
Tinct. opii	2 lb. 8 oz.
Liq. opii sed.	8 oz.
Pulv. ipecac. co.	4 oz.
Pil. plumbi c. opio (gr. 5)	1 gross
Pil. opii (gr. 1/2)	1 gross
Morphine.				
Morph. sulph.	2 dr.
Liq. morph. hydrochl.	9 oz.
Tinct. chlor. et morph.	6 oz.
Hypodermic tablets morph. sulph. (gr. 1/4)	2 tubes
(20 in each tube)				
Hypodermic tablets morph. sulph. (gr. 1/6)	2 tubes
(20 in each tube)				
Heroin.				
Tabellac heroin (gr. 1/25)	124
Cocaine.				
Tabell. cocain et pot. chlorat.	200
Ophthalmic tablets cocaine hydrochl. (gr. 1/50)	2 tubes
(12 in each tube)				

7. The outgoings that would require to be recorded under the Regulations (as amended by the Home Office letter of February

15th) would only be those relating to pulv. ipecac. co., pil. plumbi c. opio, pil. opii, and the tablets of heroin and cocaine, as these are the only transactions in which any of the drugs were dispensed at or above the scheduled percentage strength. In every other case the drugs were administered personally or were dispensed in mixtures below the scheduled strength. Such a record would, it appears to the Association, be useless as a check on illicit traffic.

8. The Association would again raise the question asked in its letter of February 3rd—namely: "In small hospitals without resident house-surgeons, in nursing homes and in private practice where a trained nurse is in attendance it is a common occurrence to leave a hypodermic injection or a sedative draught which would contain one of the scheduled drugs to be given if necessary. Would this be in conformity with the Regulations, or would the nurse or orderly be a person not authorized to be in possession of the drug?"

The class of cases above alluded to is a very common one, and unless the doctor can delegate his authority to administer the drugs personally there will be much totally unnecessary suffering. It cannot be expected, for example, that the honorary medical officers to hospitals should pay visits to those institutions merely to administer a sedative drug which up to the present has been administered, without any evidence of abuse, by trained nurses or other responsible persons.

9. The Association believes that Regulation 9 presents the following dilemma. Take the case of a person handing to a chemist, say in Brighton, a prescription purporting to be signed by a doctor in York. Either the chemist is a very careful person who declines to take the risk of deciding whether or not the prescription is really signed by a medical practitioner (he could only be sure if he were familiar with the writing), or he accepts the prescription at its face value and takes the risk of it being a forgery. In the first case the patient may be put to quite unnecessary inconvenience; in the second the Regulation is seriously impaired as a protection against unauthorized possession of the drugs.

10. Regulation 13. The Association is not satisfied with the answer given in the Home Office letter of February 15th. It is not yet clear whether Regulation 13 does or does not require that the messenger of an authorized person (either doctor, chemist, or patient) must be authorized in writing to receive the drugs. If it is meant that there is to be an authorization in writing in every case, the demand is an impossible one. If such authorization is not demanded, the uncertainties and difficulties of the pharmacist seem to be very great. Any undue difficulties placed in the way of the pharmacist will, of course, be reflected on the patient, and in due course on the doctor who gives the prescription.

11. The Association must in any case press for the exclusion of the substances mentioned in its letter of February 15th. Regulations may be necessary as regards some preparations of the drugs, but it is impossible for anyone to hold that any of the substances mentioned in that letter (with the possible exception of pulv. ipecac. co.) could be used by the illicit drug-taker. There seems no reason why they should not be excepted from any restrictions laid on prescriber, buyer or seller.

Association Notices.

ELECTION OF COUNCIL OF ASSOCIATION,
1921-22.

A LIST of the Groups of Branches in the United Kingdom for election of twenty-four Members of the Council, 1921-22, and **Nomination Form**, were published in the SUPPLEMENT of March 12th (p. 73). The **Nominations** must be in the hands of the Medical Secretary by **May 16th**.

The result of the election for Members of Council by the Groups of the Oversea Branches was published in the SUPPLEMENT of February 19th, 1921.

ELECTION OF REPRESENTATIVE BODY OF
ASSOCIATION, 1921-22.

Constituencies in Representative Body.

THE Council has finally grouped the **Home Divisions** for election of the Representative Body, 1921-22, in the same manner as for 1920-21, except that the Caithness and Sutherland Division of the Northern Counties of Scotland Branch, and the Rotherham and Sheffield Divisions of the Yorkshire Branch, have been made independent Constituencies.

As intimated to all the **Oversea Bodies**, the Council has made each Oversea Division and Division-Branch an independent Constituency.

Election of Representatives and Deputy-Representatives.

THE REPRESENTATIVES AND DEPUTY-REPRESENTATIVES for election of the Representative Body must be elected not later than June 17th, and their names notified to the Medical Secretary **not later than June 24th**. The Annual Representative Meeting at Newcastle begins on July 15th.

Special attention is drawn to the fact that the election of Representative(s) and Deputy-Representative(s) may, at the discretion of the Constituency, be carried out by General Meeting of the Constituency, or by postal vote.

MOTIONS FOR ANNUAL REPRESENTATIVE MEETING, NEWCASTLE, JULY, 1921.

NOTICES OF MOTION by Divisions, Constituencies, or Branches, for the consideration of the Annual Representative Meeting of the Association, commencing Friday, July 15th, 1921, proposing to make any addition to, or any amendment, alteration, or repeal of, any Article or By-law, or to make any new Article or By-law, or proposing material alteration of the policy of the Association in matters relating to the honour and interests of the profession or of the Association, must be published in the *BRITISH MEDICAL JOURNAL SUPPLEMENT* not later than May 14th, and for this purpose should be received by the Medical Secretary **not later than April 30th.**

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A list of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 6.30 p.m. (on Saturdays 10 a.m. till 2 p.m.).

BRANCH AND DIVISION MEETINGS TO BE HELD.

SOUTH-WESTERN BRANCH.—An intermediate meeting of the Branch will be held at Newton Abbot on Thursday, April 7th. Members should notify the Honorary Secretary, Mr. F. A. Roper (12, Southernhay West, Exeter) not later than March 25th of any cases, notes, papers, specimens, or notices of motion they may wish to bring forward in order that they may be placed on the agenda paper.

Meetings of Branches and Divisions.

MALAYA BRANCH.

THE Malaya Branch of the British Medical Association held a conference on January 20th, 1921, with the Commissioners of the National Council for Combating Venereal Diseases. Dr. MALCOLM WATSON, president of the Malayan Branch of the Association, presided, and in his opening address welcomed the advent of the Commissioners and dwelt on the importance of venereal disease to the community. Dr. HALLAM stated that the objects of the Commission were to confer with the local authorities in the Far Eastern ports with regard to the possible measures which might be undertaken to reduce the incidence of venereal disease, and spoke of the recommendations which had been approved by the National Council for the provision of free treatment, early treatment centres, and a campaign of education of the general public. He mentioned the fact that in Japan the public health department was in favour of suppressing brothels, and cited as an instance the improvement in one of the counties of Japan in which the measures had been already enforced.

Dr. D. J. GALLOWAY in his reply gave full approval to the establishment of approving of a ca principle, he was score in Singapore. He proceeded to point out the great divergence which existed between the facts as existing there and the commonly accepted ideals which were held on this subject in civilized countries, and urged that the only way by which any useful measure could be evolved to deal with the evil was by a careful study of the local conditions. To that end he moved the following resolution:

That this Association memorialize the Government of the Straits Settlements and Federated Malay States to cause full enquiry to be made as to (a) the prevalence of venereal disease, (b) the cause of that prevalence, (c) means of treatment, (d) means of prevention, and (e) the subject of prostitution generally.

Dr. RATTRAY, in seconding Dr. Galloway's proposal, stated that for the past year he had been making efforts to establish a kindred society in Malaya, giving greater prominence to the value of disinfectants in the prevention of venereal disease. Dr. Hoops gave his experiences of the value of antiveneral clinics which he had established in Kedah. Dr. HACKER spoke of his experiences with the garrison in Singapore; he was in favour of early treatment.

DRICK, Dr. GLASS, Dr. The proceedings were of Dr. Galloway's reso-

Intion, a copy of which has been forwarded to the Colonial Secretary. The Council and members of the Malaya Branch afterwards entertained the Commissioners to dinner at the Europe Hotel.

METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.

A MEETING of the Marylebone Division was held on March 16th, when Sir JAMES GULLOWAY was in the chair. The senior honorary secretary, Mr. C. Edward Wallis, was welcomed back after his recent serious illness, and Messrs. L. E. Ware and Philip Tignor were elected to fill the vacancies on the Branch Council. Dr. T. WATTS LIDEN gave a most interesting address on "Some notes on the treatment of private patients in hospitals in the United States of America and Canada," which was followed by a discussion.

MIDLAND BRANCH: NOTTINGHAM DIVISION.

THE report of the work done by the Division in 1920 shows that the membership increased from 161 to 177. During the year there were twelve Divisional meetings, four of which were combined meetings with the Society, at which scientific cussed. The Executive Co there were several smaller the Colliery Field Club Bo special meetings at various centres. In the early part of the year the Division agreed that all doctors should raise their private fees 50 per cent., and this was advertised to the public.

The Division, after a long and arduous fight with the Colliery Field Club, has just brought this dispute to a satisfactory ending. As a result of this the contract price for medical attendance on dependants of miners has been raised from 16s. 3d. to 21s. 8d. per annum per married man, in addition to the whole system being placed upon what the Executive hopes will prove to be a more satisfactory and businesslike footing. The result of these negotiations is that the salaries of the Notts colliery surgeons have been increased by £3,242 per annum, or an average of £14 10s. per colliery surgeon. Before 1916 the contract price for this was only 13s. 6d.

Again, owing to the action of the local Division, the salary for maternity and child welfare work in one district was raised from £20 to £80 for forty sessions. A scheme has already been started in some of the districts whereby neighbouring practitioners do one another's holiday work. It is hoped to develop this scheme further in the future. In addition to the above local work, the Executive Committee points out that during the year the increased capitation rates for attendance under the National Insurance Act came into force, and that the British Medical Association was largely responsible in obtaining that increase from the Government.

INSURANCE.

CHARGES OF FRAUD IN INSURANCE PRACTICE.

IN the JOURNAL of December 25th, 1920, at p. 932, we recorded that at the Manchester Assizes on November 29th Dr. J. T. Godfrey, of Royton, was convicted and sentenced to three months' imprisonment on an indictment charging him with fraudulent conversion of goods and attempting to obtain money by false pretences. The charges were preferred by the Lancashire Insurance Committee. We have now received from the Ministry of Health a communication relating to an inquiry held at Manchester on February 9th under Part VI of the Medical Benefit Regulations, 1920, in regard to Dr. J. T. Godfrey, together with the report of the Inquiry Committee, and a formal statement of the Minister's decision.

The Committee of Inquiry consisted of Mr. Hugh Gamon, barrister at law (chairman), Dr. A. Forbes, and Dr. T. A. Goodfellow. The Minister of Health was represented by Mr. L. G. Dawson, and Dr. Godfrey by Mr. John G. Mahaffy. The administrative officer and cashier of the Lancashire Insurance Committee gave evidence on oath as to the nature of the offences. It was admitted on the part of Dr. Godfrey that his conviction was on six charges, of which three related to attempts by him to obtain payment from the Lancashire Insurance Committee in respect of fictitious attendances upon insured persons, and the other three charges concerned the obtaining by Dr. Godfrey for his own benefit from a chemist of drugs and appliances by means of prescriptions written by him containing the names of insured persons from his list of patients. Dr. Godfrey, in the course of his evidence before the Committee, stated on oath that he had been unjustly convicted, contending that the evidence upon which his conviction had been obtained was to a large extent false, and suggesting that his conviction was the result of a conspiracy. He, however, brought before the Committee no evidence to support such contention, and the Committee was not able to accept his unsupported evidence of his innocence with regard to the transactions in question. They expressed themselves satisfied that all the offences, and particularly those of attempting to obtain money by false pretences, were deliberately committed.

The Minister of Health, having read and considered the Inquiry Committee's report, is satisfied that Dr. Godfrey's continuance on the Medical List would be prejudicial to the efficiency of the medical service of the insured, and accordingly decides that his name be removed as from April 1st, 1921, from the Medical Lists of the Insurance Committees for the County of Lancaster and for the County Boroughs of Oldham and Rochdale.

CORRESPONDENCE.

The New Medical Records.

SIR,—I am in practice in Scotland, in the County of Renfrew Insurance Area, and here is my experience with the new record cards and envelopes:

My record cards begin with the date January 7th, 1921, which was the date on which I received them.

On March 12th, 1921, my envelopes arrived and I proceeded to put the record cards inside. I found (1) I was duplicating on the envelope the date on the record card; (2) I must get hold of a paper cutter, or some such implement, in order to open up the inside of the "paper poke" and get the record card to reach the bottom; (3) I must double the size of my former cabinet to accommodate the envelopes and record cards, at what will no doubt be a substantial sum.

Meanwhile I have suspended operations pending an envelope opener and an enlarged cabinet.—I am, etc.,

THOS. CARRUTHERS, M.A., M.B., Ch.B.

Kilbarchan, Renfrewshire, March 17th.

The Dental Bill and Insurance Practice.

SIR,—Has any consideration been given as to how the new Dental Bill will affect panel practitioners? At the present time about nineteen-twentieths of insurance patients are treated by unqualified dentists.

I understand that under the present Regulations panel practitioners are liable to give anaesthetics for dental treatment. I presume that we shall now be compelled to attend at the surgeries of these formerly unqualified men which will cause a large increase of work. I hope I am wrong in my surmise. I shall be glad to know it.

It would be rather a Gilbertian situation if one week one is punished by the General Medical Council for giving an anaesthetic for a man, and the next week punished by the Insurance Commissioners for not doing so. Great is the power of parliamentary whitewash.—I am, etc.,

W. G. BENNETT.

Worcester, March 20th.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty: Surgeon Commander K. H. Jones to the *Fisgard*. Surgeon Lieutenant H. A. L. Guthrie to the *Robin*.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel D. A. Bourke, D.S.O., is placed on retired pay on account of ill health contracted on active service. The following temporary Captains relinquish their commissions and retain the rank of Captain: J. Anastasio, M.B.E., A. G. Wright.

ROYAL AIR FORCE.

MEDICAL BRANCH.

... are granted permanent commissions as Flight Lieutenants on their present seniority (subject to acceptance of the notification in the *London Gazette* of these officers to short-service commissions is Gray, R. E. Bell, E. A. Lumley, M.C., D. G. Boddie, H. McV., and A. E. Barr-Simm (July 13th, 1920). Flight Lieutenant D. McLaren is granted a permanent commission, retaining his present substantive rank and seniority (subject to acceptance of final conditions of service, March 31st, 1920). The notification in the *London Gazette* of September 14th, 1920, appointing this officer to a short-service commission is cancelled.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel A. B. Lyon, T.D., is appointed to command 1st London C.C.S. Lieut.-Colonel J. H. Harris, T.D., resigns his commission and retains the rank of Lieutenant-Colonel, with permission to wear the prescribed uniform. Captain and Brevet Major R. E. Barnsley, M.C., R.A.M.C., to be Adjutant of the R.A.M.C. School of Instruction, Northern Division (I.F.).

Captain P. J. Gamkin, M.C., to be Major. The following officers resign their commissions:—Major J. R. Benson, and is granted the rank of Lieutenant-Colonel. Major A. W. French, T.D., and retains the rank of Major. Captains, and retain the rank of Captain: C. F. Backhouse, A. J. H. Isles, S. L. Brimble-Meade-King, and C. E. M. Jones, C. H. Maskow, A. V. Maybury. The following officers resign their commissions and retain the rank of Lieutenant-Colonel J. E. Square, 4th Southern General Hospital. The following officers resign their commissions and retain the rank of Major: Major A. C. Roper, Captain (Brevet Major) E. G. Smith, and Captains W. L. Pethybridge, C. F. Glin, G. C. F. Robinson, B. Dyball, R. V. Solly, R. Jaques, H. Andrew, and C. D. Lindsey. 5th Southern General Hospital.—The following officers resign their

commissions and retain their rank: Major N. E. Aldridge, Captains C. H. Saunders, M. H. Way, J. L. Wright, C. Lamplough, J. E. F. Falser, A. W. Power.

TERRITORIAL FORCE RESERVE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel C. A. Lees, C.B.E., from 2nd London (County of London) General Hospital, to be Lieutenant-Colonel.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.—Section of Laryngology: Fri., 4 p.m. Cases. 4.15 p.m., Mr. A. Ryland: Epidiastroscope Demonstration of a Pharyngeal Pouch. Section of Anaesthetics: Fri., 8.30 p.m., Drs. R. L. Mackenzie Wallis and C. Langton Hewer: A New General Anaesthetic.

St. John's Hospital, 49, Leicester Square, W.C.—Thurs., 6 p.m., Chesterfield Lecture, Dr. W. Griffith: Bullous Eruptions.

POST-GRADUATE COURSES AND LECTURES.

GLASGOW POST GRADUATE MEDICAL ASSOCIATION: Lock Hospital, 41, Rottenrow.—Wed., 4.15 p.m., Dr. Madeline Archibald: Venereal Disease in the Female.

1 Fri. London: Central Ethical Committee, 2 p.m.
London: Medico-Sociological Committee, 2.30 p.m.
7 Thurs. Worcestershire and Herefordshire Branch: British Medical Association Lecture by Mr. P. L. Daniel, W.R.C.S., on the Differential Diagnosis of Acute Abbot.

APPOINTMENTS.

RICHARDS, H. A., M.A., B.Ch.Cantab., Junior Anaesthetist and Assistant Instructor in Anaesthetics to King's College Hospital. ROBINSON, G. C. F., F.R.C.S. Eng., Honorary Consulting Surgeon to East Cornwall Hospital (Bodmin), Liskeard Cottage Hospital, Fowey Cottage Hospital, Kingsbridge Cottage Hospital, Totnes and District Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s, which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

MARRIAGES.

ANDERSON—HOOD.—On the 18th March, at St. Columba's (Church of Scotland), Pont Street, S.W., the marriage of Major H. Graeme Anderson, M.D., F.R.C.S., R.A.F., of 75, Harley Street, W., to Gladys, elder daughter of Charles Hood, of Hatch End, Middlesex. JARVIS—COCKBURN.—At Duddingston Kirk, Midlothian, on March 17th, 1921, by the Rev. William Robertson, D.D., assisted by the Rev. William Serle, B.D., Captain Oswald D. Jarvis, O.B.E., Royal Army Medical Corps, to Alice, eldest daughter of the late Rev. George Cockburn, B.D., and of Mrs. Cockburn, 13, Elm Place, Aberdeen.

DEATHS.

FORT.—On March 13th, at Shorelea, Oldham, Lancs., Thomas Fort, M.R.C.S., L.R.C.P., L.M., in his 69th year. KAY.—March 11th (suddenly), at The Grove, Starbeck, Harrogate, Elizabeth Mary, wife of Walter Smith-Kay, M.D., formerly Medical Superintendent of West Riding Asylum, Wadsley, Sheffield.

number of spirochaetes rendered *hors de combat* is necessarily limited by the amount of "606" that can be brought to bear on them. The defensive process initiated or augmented by a vaccine bears no necessary proportion to the dose introduced; the effect is, it seems to me, qualitative rather than quantitative. On the other hand, as Wright himself admits, vaccine therapy is permissible only when the body is not already making its maximum immunizing response, and is also generally unsuccessful in presence of pyrexia and severe constitutional disturbances, unopened abscesses, and foul, discharging or sloughing wounds. It gives less favourable results in long-standing than recent infections. As between the direct attack of antibacterial or antitoxic serums upon the pathogenic organism or its toxins and the evocative action of vaccines the present therapeutic tendency is decidedly favourable to the latter method—that of active in preference to passive immunization.

It is an interesting, albeit somewhat speculative, question to ask how our views of drug therapy in general are being or are likely to be modified by the dominant conception of immunity. To some extent one can recognize a similar duality in the use of drugs to that involved in the distinction between vaccines and serums, active and passive immunity. "The whole ground of Physic," says Culpeper, "is comprehended in these two words, *Sympathy* and *Antipathy*;" the one cures by strengthening the part of the body afflicted, the other by resisting the malady afflicting." Here, surely, are foreshadowed the two points of view which were later to split the profession into conflicting schools of thought. There is, however, nothing really incompatible in these two points of view; belief in the efficacy of Behring's serum does not preclude faith in that of anti-enteric vaccine. In a lecture delivered last year Sir Almroth Wright described experiments proving that "in response to inoculations of a staphylococcal vaccine the blood serum and lymph acquire bactericidal powers for both staphylococci and streptococci." In fact, it would seem that immunity is not, as has hitherto been thought, merely specific; inoculation may produce collateral as well as direct immunity. This conclusion suggests the questions whether something comparable to immunity be attainable by ordinary drugs, and whether the leaning towards vaccines rather than antitoxins—towards what Culpeper calls the method of "sympathy," of "strengthening the part afflicted"—be discernible in the wider field of modern medicine.

If, as can scarcely be questioned, the legitimate resources of drug therapy include the administration for curative purposes in medicinal doses of remedies capable of producing symptoms resembling those of the malady under treatment, it seems that the conditions of success must be approximately the same as those experimentally established in and for vaccine therapy. Such a method might appropriately be termed *synergic*, in distinction from the more widely applicable *corrective* medication, of which, say, the administration of a purge on general principles, of a dose of sulphonal or barbitone for insomnia, or of a combination of alkalis for acidosis, are examples. I have more than once observed symptoms suggestive of anaphylactic shock in endeavouring to push remedies like arsenic, and I am inclined to think that much better results might be obtained in drug treatment, and particularly with definitely organotropic remedies, by a modification of dosage and periodicity based on the assumption of the occurrence of a "negative phase" or period of diminished therapeutic susceptibility. It surely favours of crudity to jump straight to our maximum dose of such potent remedies as digitalis, nux vomica or strophanthus, and to give these for weeks together at intervals of three or four hours only, although when we push digitalis to clear up a dropsy we are after all using it correctively, not curatively.

Assuming that impaired nutrition is basic in most diseases, my suggestion is that a drug capable of acting as a physiological stimulus to a given organ will in smaller doses act as a *trophic* stimulus, and that such stimuli, if maintained long enough and never exceeded, will in some cases re-establish the normal nutrition and, consequently, the normal function. Further, that the maximum trophic effect will be produced by a dose just short of that productive of an appreciable physiological effect. This dose must not be regarded as a fixed quantity; as soon as tolerance of the original dose is established it should be

cautiously increased. As regards the spacing of doses no fixed rule can be laid down, but it should be long enough to preclude such heaping up of the trophic effect as would result in functional stimulation. Thus the medicine may be given night and morning, or, in some cases, once daily or less. The common observation that a remedy continued too long "loses its effect," the facts of drug and tobacco tolerance, and the enormous quantity of alcohol that some people can take with apparent impunity, all suggest that the principle of immunity has wider application than is yet commonly realized.

A closely related subject is that of toxic idiosyncrasies, particularly those which manifest themselves in the form of coryza and bronchial asthma. Dr. John Freeman in a recent lecture showed that abnormal sensitivity to foreign proteins, such as grass pollens and animal emanations—for example, from the horse, cow, or, above all, the cat—can be detected by the production of conjunctival or cuti-reactions. In bronchial asthma, which he regards as the result of the endotoxin of the microbe causing the bronchitis, the skin reaction can be produced by using a solution of this microbe. Food idiosyncrasies can be tested for in the same way. Hypersensitiveness to foreign proteins is, he finds, commonly a family trait, but is apt to take diverse forms in its different members. I have myself often noted the occurrence of a liability to hay fever, asthma, or urticaria in members of the same family, and sometimes alternating in the same person. With regard to food idiosyncrasies, Dr. Freeman suggests that where mothers insist on faddy children finishing up their meals they are probably immunizing them against slight hypersensitiveness of this kind. In this, as in many other respects, modern mothers might with advantage revert to the sturdier methods of their Victorian forebears.

The department of modern medicine, comprised under the terms organotherapy, opotherapy, or endocrinology, may, I think, best be characterized as a realm of great expectations. We hope much of it, but, except in the treatment of such rare diseases as myxoedema, mongolism, or scleroderma, it is difficult to point to notable achievements. Although regarded as a distinctively modern method, its origin is deeply rooted in antiquity. "Dry a Bullock's, Sheep's, or Goat's bladder," writes Culpeper, "and beat it into powder, and give a drachm of it in water, vinegar, or any convenient liquor to such as cannot hold their water or use to piss abed and it will help them." In another section he affirms that the internal skin of a hen's gizzard "helpeth concoction"—that is, digestion—exceedingly; "nothing like it" if given after meals. Also he asserts that "the Brains of a Weazel dried and drunk in vinegar cures the Falling sickness." In a recent paper on the nervous system and the endocrine glands, Dr. Sybil Welsh suggests that below the level of the most simple type of nervous stimulus there is a set of systems of chemical control, aiding the co-ordination of the processes of nutrition, growth, and reproduction. In spite of the valuable work of Blair Bell and others, our knowledge of the mutual dependencies and reciprocal actions of the endocrine glands, and even of their individual effects, is still inadequate for confident generalization as to their therapeutic rôles. We are as yet mainly confined to the phase of empirical gleanings. The available secretions may be used in one of six ways: (1) diagnostically, to determine whether symptoms be due to excess or deficiency; (2) to compensate for a deficiency; (3) homo-stimulatively; (4) hetero-stimulatively—for example, in giving thyroid to promote ovarian secretion; (5) to inhibit excessive activity, as in the use of mammary extract to diminish ovarian activity; and (6) physiologically and occasionally, as in the use of adrenaline as a haemostatic or pituitrin to facilitate parturition. Of these six methods, by far the commonest and, so far, the most successful, are the second, of which thyroid feeding is a familiar example, and the last. It is in the exploitation of the homo- and hetero-stimulative and also of the inhibitory potentialities of endocrine remedies that the lack of adequate guidance is at present most evident. The treatment by pituitrin injections of uterine inertia, previously the commonest of indications for forceps delivery, is in my opinion the greatest advance made in obstetric practice for the past quarter of a century. I have been favourably impressed by the effects of parathyroid extract in cases of epilepsy. In one case of twenty-five years' standing the patient has been able to discontinue entirely the large doses of bromide she had been

taking for many years, and the seizures, although not entirely checked, are milder and followed by less mental disturbance. This drug is worth trying also in paralysis agitans, chorea, and the tremor of "shell-shock." Thyimus gland extract is indicated in cases of rachitis and infantile marasmus, and is said to have cured some cases of carcinoma. Pineal gland is recommended for children of backward mentality, also for premature mental failure. Cases of genital infantilism in girls and young women are benefited by ovarian feeding, also some cases of hysteria and painful menstruation. Extracts of the corpora lutea are said to alleviate the psycho-neurosis of the natural or artificial menopause, and of pregnancy, and to diminish the risk of abortion. Mammary gland extract is indicated in those forms of menorrhagia, metrorrhagia and hysteria which are attributable to excessive activity of the ovaries, and will sometimes check the growth of uterine fibromyomata.

One frequently sees cases in which girls and women show considerable enlargement of the thyroid gland without any of the recognized symptoms of cretinism on the one hand or of Graves's disease on the other. Whatever the explanation, such patients are often benefited by the cautious administration of thyroid extract. Some years ago Maranon published the observation that in 87 per cent. of cases of hyperthyroidism slight friction of the skin of the neck, near or over the gland, readily produces an erythema, sometimes accompanied by swelling. If this test be reliable, hyperthyroidism is the exception in the numerous cases of thyroid enlargement I have seen recently. It may well be that perverted rather than merely excessive or decreased activity is the commonest concomitant of such enlargement.

To sum up, it may be said that, while the note of mastery which distinguishes modern surgery is still to seek in medicine, there are signs of a growing intimacy of touch and sureness of method. The prognosis is good.

VOLUNTARY HOSPITAL FINANCE.

INTERIM REPORT OF THE MINISTRY OF HEALTH COMMITTEE.

The Committee appointed by the Minister of Health on January 25th, under the chairmanship of Viscount Cave, "to consider the present financial position of voluntary hospitals, and to make recommendations as to any action which should be taken to assist them," has made an interim report dated March 9th.

CONTRIBUTIONS BY APPROVED SOCIETIES.

The Committee states that the evidence already received has convinced it "that it is desirable, in the public interest, to maintain the voluntary system of hospital management, and also that—mainly owing to the large increase during and since the war of salaries and wages and the cost of provisions and materials—many of the hospitals are faced with a serious deficiency of income to meet necessary expenditure." The Committee intends in due course to make further recommendations, but its interim report is issued in order to deal with a pressing matter—namely, the propriety of the approved societies making contributions. The following is the text of the paragraphs dealing with this matter:

We understand that the quinquennial valuation of approved societies under the National Health Insurance Acts, which is now in hand, shows a considerable surplus over the amounts required for the purposes of the Acts. Excluding Ireland, the valuation of 4,926 societies and branches, containing 2,558,123 members (out of a total of approximately 10,000 societies and branches completed on nearly 15,000,000 members), which had been completed on December 24th last, showed a total disposable surplus of £2,171,576; and it is anticipated that when the valuation is completed the total disposable surplus of all the approved societies will not be less than £7,000,000. This result is attributed to the reduction, to conditions arising out of the war, such as the reduction, owing to war conditions, of sickness, disablement, and maternity claims, and the release of reserves in respect of members killed on active service.

Under the provisions of the Acts the societies are empowered to submit to the Minister of Health for approval schemes for utilizing the disposable surplus in providing additional benefits during the next five years; and the list of additional benefits authorized by the Acts and

the Regulations made thereunder includes, besides such matters as increase of sickness, disablement, and maternity benefits, and the provision of dental treatment, the "payment of the whole or any part of the cost of the maintenance and treatment of members in a hospital or convalescent home."

We are strongly of opinion that, in the interests both of the hospitals and of the societies, the schemes to be approved should provide for the application of a substantial part of the disposable surplus in providing a contribution towards the cost of the maintenance of members in hospitals. It will not, we think, be denied that the work of the voluntary hospitals is of great value to the approved societies and their members. Of the patients treated at the hospitals a considerable portion, about 30 per cent. of the out-patients and a larger percentage of the in-patients, are insured persons, and the effect of hospital treatment is not only to relieve these patients from suffering, but also to reduce the periods during which they are a charge upon the insurance funds. The fact that while depleting the hospital funds the war has had the effect of greatly increasing the surplus available to the approved societies, seems to provide a special reason for the consideration by the societies of the claims of the hospitals. The power given to the societies by Section 21 of the 1911 Act to subscribe to hospitals has been little used, doubtless owing to the anxiety of those concerned in the management of societies that their resources shall be sufficient to meet all claims; but now that a surplus is in sight it seems probable that a different view will be taken.

The method which should be adopted in order to secure the above result requires some consideration. The contribution of an approved society might take the form either of a weekly payment towards the cost of the maintenance of any member of the society who might become an in-patient in a voluntary hospital, or of a quarterly or yearly subscription for the benefit of the hospital or hospitals concerned; but in the latter case some amendment of the regulations would appear to be required. In either case an arrangement might (if so desired) be made with the hospitals for relieving the members of the society from any obligation to make further payments in respect of their maintenance or treatment.

We have reason to believe that some of the largest approved societies would be glad to see these proposals generally accepted, and that the hospitals would welcome such a result.

We are aware that it is not the desire of the Ministry of Health to interfere unnecessarily with the schemes submitted by the different societies for the utilization of their surplus funds. But we are confident that if the proposals here made were brought to the notice of the members the general feeling would be in favour of providing this measure of assistance to the hospitals, and so of making some return for the great benefits which those institutions have so long and so generously conferred upon them.

We therefore recommend that the Ministry

- (1) should make any necessary amendment in the regulation;
- (2) should forthwith bring this matter to the notice of the societies concerned and advise them as to the amount of the contributions which might reasonably be made out of the available surplus; and
- (3) should not approve any scheme for the disposal of a surplus until the suggestion has received due consideration.

We should have preferred to include these recommendations in our general report, so that their relation to other parts of the report might be seen; but we understand that the matter is urgent, as some of the societies are now engaged in framing schemes under the Act.

The report is signed by all the members of the Committee—Viscount Cave, the Marquis of Linlithgow, Sir Clarendon Hyde, Sir W. B. Peat, Mr. Vernon Hartshorn, M.P., and Mr. R. C. Norman.

A SMALL epidemic of small-pox has recently occurred at Chicago, being apparently due to a case being mistaken for varicella. Up to December 116 cases had been notified. The second International Congress of Eugenics will be held in New York from September 22nd to 28th. Further information can be obtained from the Secretary, Dr. C. Little, American Museum of Natural History, 77th Street, New York City.

THE mortality from tuberculosis in Austria has considerably increased during the last few years. Before the war it was on the decline, the number of deaths from this cause in Vienna among women being 2,635 in 1914. During the war this figure began to increase, and is now 5,018. The mortality is highest between 35 and 65.

British Medical Journal.

SATURDAY, MARCH 26TH, 1921.

MUNICIPAL MEDICINE.

It is generally recognized that the extension of plans for the municipal treatment of certain classes of patient and certain kinds of disease is a matter of serious moment to the private practitioner. We have seen the institution of medical inspection of school children, then of a tuberculosis medical service, followed by maternity and child welfare centres, and recently by venereal disease clinics. Still more recently proposals for the establishment of municipal hospitals, some of which have been carried out, have afforded further evidence of the trend of municipal enterprise and have convinced the general profession of the need of watching developments very closely.

All these matters have for some time past been under the consideration of various committees of the British Medical Association, and on March 16th a conference of these committees was held in order that the present situation might be discussed from all points of view. The conference was by invitation attended by some representatives of the medical officers of health. The hope that in this way some basis of understanding might be reached was not disappointed, and the conference at an early stage affirmed its desire to find some means of reconciling the difference between medical officers employed in municipal clinics and municipal hospitals on the one hand, and private practitioners in certain areas on the other. After this gratifying exhibition of professional solidarity the conference proceeded to the discussion of details, but though it sat for some four hours, it did not reach the hospital question. With regard to clinics, however, the ground was to some extent cleared. The desire of the representatives of clinical medicine in the committees of the British Medical Association was that the clinical work of clinics should be carried out by private practitioners. Many, perhaps the majority of medical officers of health, have preferred that clinics should be conducted by whole-time officers, who will be more directly under their personal control; and municipalities have been moved to take the same view on the ground of economy, since they believe that the whole-time officer would not cost so much as a rota of practitioners. A resolution, however, was adopted at the conference, moved by a member of the staff of a voluntary hospital, and seconded by the medical officer of health of a large urban district, to the effect that clinical work done for a public health authority should, wherever possible, be carried out through the agency of private practitioners, subject to conditions to be agreed upon.

The remainder of the time of the conference was mainly given to a discussion with regard to the medical inspection of school children. It was agreed that the wise and proper course for a local authority to take was to invite local practitioners to submit a scheme for giving advice and treatment at school clinics and also at maternity and infant welfare centres; it was agreed also that specialist treatment in such clinics should be given by part-time specialists. Both these recommendations were qualified by the phrase

"if possible." It is, of course, plain that the method is possible; it is followed in some other countries; the chief objection to it in this country would appear to be the risk of some extra expenditure. A further principle agreed upon was that those responsible for medical inspection ought not to refer a case to the clinic direct should the patient have a private practitioner or be willing to consult one. On the other hand, it was agreed that practitioners of the area ought to have the right themselves to refer cases to the school medical officer for treatment.

The near resemblance that may be traced between the recommendations of the Medical Consultative Council of the Ministry of Health with regard to clinics, and the decisions of the conference last week on the same subject, gives good ground for believing that they express the considered views of the profession. We shall hope for further guidance on the hospital question, for it is important that its professional aspects should be thoroughly considered and the opinion of the profession presented to the public, as far as may be possible, simultaneously with the final report of the Voluntary Hospitals Committee appointed by the Minister of Health under the chairmanship of Lord Cave. We give elsewhere the text of the operative clauses in the interim report of this Committee. It will be seen that the members reached the unanimous conclusion that it is desirable in the public interest to maintain the voluntary hospital system of management. In expressing this view the Committee is in agreement with the British Hospitals Association, with King Edward's Hospital Fund for London, and, we believe, with the majority of the medical profession.

While it is recognized that it is undesirable that general hospitals should be converted into municipal or state institutions, thereby losing the advantages of voluntary administration and control, the necessity for finding additional sources of income is equally generally admitted. Lord Cave's committee makes a definite recommendation—namely, that in the interest both of the hospitals and of the approved societies a substantial part of the large surplus funds held by those societies should be used to provide contributions towards the cost of the maintenance of their members when in hospital. The total disposable surplus of the approved societies at the end of 1918 will, it is believed, when the valuation is completed, prove to be not less than seven millions. The Committee estimates that of persons treated at the hospitals, about 30 per cent. of the out-patients and a larger percentage of the in-patients are insured persons; the effect of hospital treatment is not only to relieve the patients from suffering and disability, but also to reduce the periods during which they are charged upon the insurance funds. The war, while depleting the hospital funds, has had the effect of greatly increasing the surplus available to the approved societies, and this would seem a special reason why the societies should give consideration to the claims of the hospitals. Section 21 of the Insurance Act, 1911, gave power to an approved society to grant subscriptions or donations to hospitals; it appears that this power has been little used. Lord Cave's committee has reason to believe that some of the larger approved societies would be glad to help the hospitals, and mentions two alternative methods: either the approved society might make a weekly payment towards the cost of the maintenance of any member who is an in-patient, or it might make a quarterly or yearly subscription to the hospital. The choice of method will require careful consideration, and is a matter upon which the medical profession will undoubtedly wish its opinion to be heard.

SPLENECTOMY IN PERNICIOUS ANAEMIA.

AMONG the numerous methods of treatment proposed and practised for pernicious anaemia the most heroic is splenectomy. It was introduced about ten years ago, and, although never popular in this country, it has not entirely escaped attention, for in 1914 Thursfield and Gow,¹ in an analysis of 21 cases collected from the literature, 11 being from Mihsam's clinic, showed that the red blood count was increased in all; with full recognition of the natural tendency of the disease to show remissions, they conclude that the operation afforded a fair promise of prolonging life, and even of making possible an active existence, at any rate for a time. In 1917 L. B. Wilson and Giffin² reported 7 cases at the Mayo clinic with temporary improvement; and in 1917 Giffin,³ in bringing this number up to 31, stated that there was a well marked favourable reaction in 78 per cent. of the patients who recovered from the operation, the immediate mortality of which was very low; most of the cases were so recent that no conclusions as to the duration of post-operative survival could be then drawn.

Giffin and Szlapka⁴ have now published a report on 50 cases, including the 31 mentioned above, in which the operation had been performed more than three years previously. The immediate operative mortality was 3 (or 6 per cent.), and, though higher than in chronic splenomegalic haemolytic jaundice, was considerably lower than in chronic splenic anaemia. Out of the 47 patients 42 have now succumbed, but 10 survived for more than three years, and 5 of those were alive and well in November, 1920, with an average of six years' illness, and an average interval since operation of four and a half years; the average total duration of the disease in the 10 cases was four and a half years, or longer than the average expectation of life (two to three years) in pernicious anaemia, and hence it is concluded that splenectomy prolonged life in 20 per cent. of the 50 cases. Estimation of bile pigments in the duodenal contents by a modification of Schneider's method suggested that haemolysis is less after than before operation, and there was some reason to believe that after splenectomy the progress of spinal cord changes was less rapid than would have been anticipated. Splenectomy appears to stimulate the bone marrow, for large showers of nucleated red cells may appear in the blood; but this is not an infallible index of the patient's post-operative progress, for several of the most successful cases showed few nucleated reds and only slight leucocytosis. The cases were selected from patients between 35 and 45 years of age, with a history of a year or less of illness, a favourable blood picture, namely, a polymorphonuclear rather than a lymphocytic predominance, absence of well-marked leucopenia, and with little if any evidence of degeneration of the spinal cord. But the writers finally conclude that there are not any features of the disease that can be relied on to indicate a favourable result from splenectomy, though cases with signs of acute haemolysis show a more pronounced immediate improvement after operation.

In contrast to this surgical estimate of the effect of splenectomy Bloomfield's critical analysis of 57 cases of pernicious anaemia treated in various ways at the Johns Hopkins Hospital may be recalled⁵; he found no definite evidence that transfusion of blood (26

cases), splenectomy, or elimination of focal infections prolonged life. By that time (1918) splenectomy had been abandoned at the Johns Hopkins Hospital, 6 out of 8 cases having terminated fatally without clinical improvement or prolongation of life in any instance. In five of the cases transfusion of blood was performed after splenectomy, but there was not any proof that the transfusion "held" any better after removal of the spleen. Bloomfield's figures of splenectomy are much smaller than Giffin's, but they were controlled by other series of cases treated in other ways, and thus are valuable.

THE NEW TUBERCULOSIS BILL.

THE National Insurance Act, 1911, required Insurance Committees to make arrangements to the satisfaction of the Insurance Commissioners (now of the Ministry of Health) for providing treatment in sanatoriums or other institutions, for insured persons suffering from tuberculosis; and powers were given to the Committees to extend this benefit, if considered desirable, to the dependants of insured persons. The Act had not been in force very long before it became apparent that if the best results were to be obtained those persons who were not insured would also have to be considered. The Government accordingly undertook to provide out of national funds one-half of the net expenditure incurred by county councils and county borough councils in connexion with those tuberculosis schemes which included provisions making them available for the entire population; we believe we are right in stating that at the present time there are only two or three of these authorities whose schemes have not been approved, and that the Ministry of Health withholds approval from any scheme which does not provide for the non-insured equally with the insured. As there seemed no longer any justification for differentiating between insured persons and non-insured persons, opportunity was taken in the National Health Insurance Act, 1920, to provide that sanatorium benefit, except in the case of Ireland, should no longer be included in the benefits conferred by the National Insurance Act of 1911, and after April 30th next this special benefit to insured persons ceases. This means that insured persons who are tuberculous will be entitled to appropriate treatment not because they are insured but because they are tuberculous. In those districts in which satisfactory arrangements for treatment have not been made by the county council or county borough council the inhabitants, after April 30th, will be placed at a disadvantage compared with those living in other parts of the country where the local authorities have had a fuller sense of their responsibilities. With the object of removing this disability in England and Wales, Dr. Addison, on March 16th, introduced the Public Health (Tuberculosis) Bill into the House of Commons. This measure lays down that adequate arrangements for the treatment of tuberculosis shall be considered to have been made by a county council or county borough council if the scheme for carrying out such treatment has received the approval of the Local Government Board, the Minister of Health, or the Welsh Insurance Commissioners. But in those cases in which a council has failed to make adequate arrangements for such treatment the Minister of Health may do what is required, after giving the council in question an opportunity of being heard on the matter. The cost of establishing and carrying out a scheme of the Ministry of Health is to be borne by the council concerned. Although the main object of this bill is similar to that embodied in the bill presented by Dr. Addison in November, 1920, and subsequently withdrawn, it differs in some material respects. For example, the bill of 1920 empowered county councils, county borough councils, and the Metropolitan Asylums Board to provide and maintain

¹ Thursfield and Gow: *St. J. Hosp. Rep.*, 1914, 1, 26.

² Wilson and Giffin: *Ann.*, 1917, 1, 423.

³ Giffin: *Journ. Amer. Med. Assoc.*, 1917, 1, 1181.

⁴ Giffin and Szlapka: *Journ. Amer. Med. Assoc.*, 1921, 1, 1181.

village settlements. It also enabled county councils, county borough councils, and metropolitan borough councils to engage in propaganda work relating to the prevention and treatment of tuberculosis and to contribute to the expenses of voluntary bodies established for the purpose of assisting persons suffering from tuberculosis or their families. These enabling clauses are not in the present bill, but a new clause has been inserted empowering the Minister of Health to give conditional approval of an institution for the treatment of tuberculosis or to withdraw his approval altogether. A very useful provision in the new bill is that which enables county councils and county borough councils to delegate their powers in relation to the treatment of tuberculosis to a committee upon which there may be appointed, either by the council or by the committee itself, persons who are not members of the council but who are specially qualified by training or experience in matters relating to tuberculosis. Two-thirds of the members of the committee must, however, be members of the council. The National Insurance Act, 1911, in Section 64 (3) made provision for establishing through an Order of the Local Government Board a joint committee from county councils, county borough councils, and other local authorities, except Poor Law authorities, for the purpose of providing sanatoriums and other institutions. This subsection is repealed in the present Tuberculosis Bill, and there is substituted for it a clause through which such a joint committee can only be formed from county councils and county borough councils. There can therefore be no co-operation between any local authorities other than these bodies, and in some quarters this will be looked upon as a distinct defect in a measure which in other respects calls for no adverse criticism.

THE MANCHESTER RADIIUM INSTITUTE.

THE annual report of the Manchester and District Radium Institute, compiled by Dr. Arthur Burrows, radiologist, states that the number of patients applying for treatment during 1920 was 834, or 157 more than in the previous year; of these patients, 552 were suffering from malignant disease. Sixty-five cases of carcinoma were rendered free from signs and symptoms of the disease during the year; the organs affected were: the breast in 7 cases, the cervix of the uterus in 32, the larynx in 1, the lip in 3, the mouth and tongue in 5, the nose in 2, and the skin in 15. The number of rolent ulcers treated was 100, and of these 45 were cured. The number of cases of carcinoma of the cervix of the uterus seen during the year was 128; 3 were found unsuitable for treatment, 1 died, 8 were not improved, 29 abandoned treatment too early, 51 were improved, and, as already stated, 32 were well at the end of the year. The total is made up by 4 cases submitted to prophylactic radiation. The question whether the use of radium can replace operation in the treatment of early carcinoma in this situation is not yet decided, but the future is considered to be promising. Although the methods employed in the early years of the Institute were not as efficient as at present, a number of cases regarded at the time as inoperable and treated by radium were alive and well five, four, and three years later. During 1920 six cases classified as improved were regarded as inoperable before radium treatment was applied; they have since been operated upon. Appended to the report is a reprint of an article communicated by Dr. Fletcher Shaw and Dr. Burrows to the Section of Gynaecology of the Royal Society of Medicine on the use of radium to render possible hysterectomy for advanced carcinoma of the cervix; an account of this article was published in our columns of June 12th last, p. 806, and it was noted that during the discussion which followed its reading the opinion was expressed that it might be proper to operate on the second day after the completion of the exposure to radium; that is to say, at a time when the destructive action of the emanation on the malignant

cells has been completed, and the hard fibrous tissue, which at operation later on may make dissection difficult, has not yet been formed. The report now before us states that recently some operable cases had been given doses of radium, and the uterine removed three days later, but we do not find that the final result is stated. Of 86 cases of cancer of the mouth and tongue which applied for treatment, 3 received prophylactic radiation only, 17 were found unsuitable for treatment and 15 abandoned it too early, 5 cases died, and 9 were not improved; 32 were improved and 5 were well at the end of the year. Among the cases returned as improved was a considerable number in which the primary growth of the mouth had disappeared, but secondary glands were still present in the neck. The problem of secondary deposits still remains, it is said, the most difficult factor in dealing with cases of carcinoma of the mouth. Among the patients suffering from non-malignant disease were 54 cases of exophthalmic goitre; of these, 3 were deemed unsuitable for radium treatment, 10 did not persevere with it, 2 were not improved, 1 died, 37 improved, and 1 was well at the end of the year. A long period must be allowed to elapse before any definite opinion can be expressed. In a paper read to the Electro-therapeutic Section of the Royal Society of Medicine by Dr. Burrows and Mr. Woodburn Morison in March, 1920, the opinion was expressed that no other treatment gave such safe, uniform, and promising results as irradiation of the thyroid gland. In view of the alarming accounts of grave anaemia resulting from the handling of radium for therapeutic purposes, Dr. G. E. Loveday made some examinations of members of the staff of the Manchester Institute; at present the results are incomplete, but the inquiry will be continued. A new building provided with beds will be taken into use by the Institute this year.

CONGRESS OF RADIOLOGY AND PHYSIOTHERAPY.

THE forthcoming Congress of Radiology and Physiotherapy, organized by the Electro-therapeutic Section of the Royal Society of Medicine and the British Association of Radiology and Physiotherapy, will be held in London on Thursday, Friday and Saturday, April 14, 15th, and 16th, 1921, under the presidency of Sir Humphry Rolleston, K.C.B. The Congress will open at 10 a.m. on April 14th at the Royal Society of Medicine. On each day there will be papers and discussions in each of the three Sections—A, Radiology; B, Electrology; and C, Physiotherapy. On the morning of April 14th, Section A will discuss diseases of bone, Section B the action of the direct (constant) current on the tissues in health and disease, and in Section C there will be addresses on physical training and on the Chartered Society of Massage and Medical Gymnastics. In the afternoon Section A will meet at St. Bartholomew's Hospital; papers will be read on the intraperitoneal injection of oxygen, and visits will be paid to radiographic departments of selected hospitals. Members of Section B will visit the electrical departments of selected hospitals, and Section C will discuss the treatment of cardiac disorders by physical means. On April 15th Section A will discuss the normal stomach, Section B the uses of electrical methods in the diagnosis and prognosis of paralysis, and Section C physical treatment as an aid to orthopaedic surgery. In the afternoon Section A will discuss the abnormal stomach, and Sections B and C will meet for a joint discussion on re-education of muscles. On April 16th Section A will discuss deep therapy and radium therapy, Section B the physiological action and therapeutic uses of high frequency currents, and Section C backache and referred pain. In connexion with the Congress there will be an exhibition of x-ray and electrical apparatus, a dinner, visits to the Universities of Oxford and Cambridge, and a demonstration of physical training, organized by the Ling Association, at the Royal Albert

Hall on April 16th, at 2.30 p.m. Representatives from France and Belgium will take part in the proceedings, and communications may be made in French or English. The Secretary-General is Dr. G. Harrison Orton, and the Honorary Treasurer, Dr. J. Metcalfe, to whom subscriptions (2 guineas for English members and 40 francs for French and Belgian members) should be forwarded at the Royal Society of Medicine (1, Wimpole Street, London, W. 1).

THE MEDICINE OF ANCIENT EGYPT.

PROFESSOR ELLIOT SMITH read an interesting paper on the ancient medicine of Egypt before the Section of the History of Medicine of the Royal Society of Medicine on March 16th. In the whole of its history, he said, medicine had been drawing upon knowledge not primarily acquired for the diagnosis and treatment of disease; and the further back into history inquiry was pushed, the more striking did this fact appear. Egypt occupied an important place in the beginnings of medicine. The elaborate methods followed for the preservation of bodies made it possible to ascertain the nature of some of the disorders from which the individuals had suffered during life. The practice of mummification itself had a far-reaching effect in acquainting men with the nature of materials that would preserve the body, and certain of these materials, such as balsams, were used later on as therapeutic agents. Among the numerous photographs exhibited was one of a fractured jaw revealing a blood stain after twenty centuries. So wonderful was the preservation of the bodies that even the contents of the alimentary canal could be examined. In the stomachs of small children the remains of a mouse were often found. The custom of giving a mouse as a remedy to children *in extremis* was mentioned by Pliny, and had its echo in our own time when, in some parts of the country, the mouse was thought to have healing properties—a striking instance of the persistence of custom through long ages. The idea of the mouse as a life-giver was probably associated with the fact that after the inundations of the Nile mice appeared in great numbers, and it was a belief firmly maintained by the Egyptians that they were formed of Nile mud, the substance of the life-giving god. The fundamental principle underlying the practice of medicine in Egypt was that illness was due to deficiency of vital substance, and that, therefore, the rational method was to give to the patient an additional dose of such substance. Blood was regarded as the substance of life, and if blood was not given in illness, red ochre or some red-coloured substance was substituted. Butter, which was often found in the mouths of mummies, was supposed to perpetuate existence by drawing upon the life-giving properties of the cow. Lotus flowers and other plants were used in the same way, and although the great majority possessed no therapeutic properties, some came to be used as drugs, and their use continued even into modern times. Professor Elliot Smith next showed photographs of splints of the pyramid age, and remarked that the same type existed in Abyssinia to-day. Sculptures had been discovered showing that the operation of circumcision or some simpler form of incision was practised in the earliest beginnings of Egyptian history. Other sculptures showed that patients were massaged, though with what object was not clear. The Egyptians never put the knowledge of dissection, acquired by embalming, to any practical use in medicine, but they made it possible for the Greek physicians of about 300 B.C. to practise dissection in Alexandria, a practice forbidden by popular prejudice in Greece itself. In the bodies of many persons of over 30 years of age found in pre-dynastic cemeteries there was evidence of arthritis in various stages. Several photographs showing extensive mastoid disease were exhibited. Another series showed tuberculous disease of the spine with unmistakable evidences of psoas abscess. At the time he began his investigations in Egypt certain

French observers had expressed the view that the appearances seen in bones from some pre-dynastic bodies were due to syphilis. His own examination of the specimens, however, showed that the damage to the bones had been inflicted by beetles after death. Altogether, with his collaborators, he had examined some 40,000 bodies in every part of the Nile valley belonging to every period of Egyptian history; in no single case was evidence of syphilis detected. He had found no evidence that trephining was practised in ancient Egypt, although the operation was performed in other parts of North Africa. The point was illustrated by a photograph showing a depressed fracture in the process of healing, which had erroneously been supposed to be an example of trephining. Skulls from the period when heavy full-bottomed wigs were worn showed characteristic thinning symmetrically disposed on the parietal bones. In the early Christian period one example of leprosy and one of gout had been found among aliens from Syria, but none of either disease at earlier dates. In concluding his lecture, Professor Elliot Smith recalled that Herodotus had stated that the bodies of women were not mummified immediately, as in the case of men, but were kept for a few days. This statement was confirmed by finding flies and larvae embedded in the resinous material used in the process of preservation.

BIRTHS, MARRIAGES, AND DEATHS.

THE Registrar-General's quarterly return for England and Wales shows that the births registered in the fourth quarter of 1920 numbered 208,380, being 21,500 fewer than in the preceding three months, and 15,200 fewer than in the corresponding quarter of 1919. The registered deaths were 115,603, being some 21,900 more than in the preceding three months, and 843 more than in the corresponding quarter of 1919. The births corresponded to an annual rate of 22 per 1,000 total population; the deaths to an annual rate of 12.5. Influenza was said to be either the primary or a contributory cause in 1,396 deaths, or 1.2 per cent. of the total deaths registered. There was no fatal case of small-pox. Infant mortality, measured by the proportion of deaths under 1 year to registered births, was equal to 85 per 1,000, being 19 per 1,000 below the average of the ten preceding fourth quarters. While the mean temperature for the quarter was above the normal in all districts, the total rainfall was everywhere below the normal, and throughout the greater part of the country the mean daily amount of sunshine was above the normal. As has already been indicated in the Registrar-General's provisional return,¹ the numbers of births and marriages in England and Wales during 1920 were the highest ever recorded, while the number of deaths was the lowest since 1862, when the population was about 20 millions. The natural increase of population (by excess of births over deaths) was not far short of half a million in 1920, and this also was the greatest on record. To make a bumper year complete, the marriage rate was higher and the total death rate and the infant mortality were lower than in any other year on record. Even the birth rate had something to be proud of, being the highest since 1909.

CANCER AND THE PUBLIC.

WHEN the lay press takes to the discussion of medical problems, as it does from time to time, the journalistic efforts are generally ludicrous and often pathetic. Of all the problems there is none more appealing to the excitable young journalist than that of cancer. Here he can dwell on "the mysteries that baffle our greatest scientists," or animadvert on the conservatism or worse of our doctors, who are sitting with folded and nerveless hands, incompetent to stay the awful scourge. Unaware of what is known and what is being done, he too often assumes that the whole subject is hid in impenetrable darkness, and that it is his duty to stir up a lethargic profession. He may

¹ BRITISH MEDICAL JOURNAL, January 29th, 1921, p. 173.

even tell us sometimes how to set about the solution. From the foreign correspondents of the daily journals we learn, at one time, that some savant has found the cause of cancer; at another, that a second savant, of whose name and existence we were ignorant, had hit upon the cure. Some newspapers, indeed, leave the subject severely alone, but in these days, when the man in the street clamours for a simple exposition of Einstein's theory, and problems in biology are freely discussed, it is to be expected that the public may reasonably demand a stocktaking of the knowledge that has been gained in the study of malignant disease, for there can be few families in this country in which some member has not died of cancer. It is unfortunate, however, that the writers who take it upon themselves to instruct the interested public are seldom in a position to know the facts of the case. Recently there has been something like an epidemic of "stunt" articles, and the alleged increase in cancer mortality in England and Wales as disclosed by the Registrar-General's report has formed the text for a mass of pseudo scientific nonsense. It is admittedly difficult to treat the questions adequately in short compass or in popular language, and some of our laboratory experts object to having their plants so frequently pulled up to display the roots. Amongst these newspaper articles on cancer we have noticed one which should serve as a model to the journalist. The writer of an article in the *Evening Standard* of March 16th, discussing the question of the increase of cancer, gives ten facts known about malignant disease which it is of advantage to the public to know. Whoever the writer may be he knows the subject, and has the ability to put the position clearly in few words, and we gladly congratulate the newspaper on the article. *Si sic omnes!*

IMPORTED SMALL-POX.

We are indebted to Dr. D. S. Davies, M.O.H. Bristol, for a copy of his report on a recent outbreak of small-pox in that city. As on several previous occasions during the last thirty years in Bristol, the first case was a man engaged in unloading ships. This man, a dock labourer, had been working in three ships at Avonmouth between November 16th and December 22nd. It seems probable that he contracted the disease from infected sacks, as one of the vessels came from an infected Rumanian port. Some time in December he apparently developed a mild attack of small-pox, which did not cause him to be absent from work for more than four days. He had been vaccinated in infancy and showed three marks. On January 22nd a medical examination revealed the presence under the thick skin of the sole of one undoubted deep-seated pustule. He communicated the disease to his wife and son, and, so far as is known, to them only. The wife, who had been vaccinated in infancy and showed four good scars, sickened on January 2nd, developed a modified discrete eruption on January 4th, and had secondary fever. The son, aged 5, unvaccinated, sickened on January 2nd, and had the eruption on January 4th; it was a semi-confluent attack, becoming haemorrhagic in the pustular stage, and the child died on January 12th. The other child of the family, a daughter aged 2, who had been vaccinated in 1920 in order to qualify for a baby show, though equally exposed to infection, has remained in perfect health. There had been no small-pox in Bristol since 1915, and the nature of these two cases was at first overlooked, and they were not notified until January 8th. Between January 2nd and January 8th twelve persons visited the house; one, a woman aged 36, who had been vaccinated in infancy, nursed the patients daily, and was revaccinated on January 9th; on January 17th she had fever, and an eruption on January 19th. Her daughter, a girl aged 8, unvaccinated, visited her mother on January 5th; she was vaccinated on January 9th, and had fever on January 16th, and the eruption on January 18th. A

domestic servant, aged 24, a sister of the woman who nursed the child that died, was another visitor; she had not been vaccinated in infancy but was vaccinated on January 10th; she had fever on January 17th and the eruption on January 19th. Another woman, aged 23, sister of the last named, unvaccinated in infancy and vaccinated on January 10th, also visited the cases; she developed fever on January 17th, and the eruption on January 20th. All these patients recovered. The eight other persons who visited the house escaped infection. In spite of the delay mentioned subsequent cases were, it will be noted, entirely limited to "home-contacts." The incident illustrates the value of informed supervision. In 1903 there were fifteen introductions of small-pox, and in nine of these no resulting case followed, nor in any instance did more than ten cases result. To maintain such control requires experience coupled with much work, the necessity for which might be avoided by the simple expedient of vaccination.

CONGRESS OF MILITARY MEDICINE.

We announced some time ago that the Belgian Army Medical Service was organizing an international congress of military medicine and pharmacy. This will be held at Brussels from July 15th to the 20th next, under the presidency of Dr. Wibin, Inspector-General of the Belgian Army Medical Service. The following subjects will be under consideration: (1) The general organization of army medical services and their relations with Red Cross societies; (2) clinical and therapeutic study of poison gases used during the war by the Central Empires, the results of their action upon the body and their influence upon the pensioned soldier; (3) the antituberculosis and antivenereal campaigns in the army; (4) the lessons of the war in the treatment of fractures; (5) purification of water on campaign. All reports and communications on the above subjects should be addressed to the Secretary-General of the Congress, Military Hospital, Liège, Belgium, before May 1st.

DURING the annual meeting of the British Medical Association at Newcastle, the Popular Lecture will be delivered by Professor Arthur Keith, M.D., F.R.S., on Friday, July 22nd, at 7.30 p.m. The subject he has chosen for his lecture is "Evolutionary wounds, their healing, and the part they play in the evolution of the human body." The lecture will be illustrated by lantern slides.

At the next meeting of the British Association, to be held in Edinburgh under the presidency of Sir Edward Thorpe from September 7th to 14th, 1921, Sir Walter Fletcher will be President of the Section of Physiology, Professor C. Lloyd Morgan President of the Section of Psychology, and Sir James Frazer President of the Section of Anthropology. A joint sectional meeting will be held to discuss problems of biochemistry.

Medical Notes in Parliament.

Venereal Disease.

DISCUSSION IN THE LORDS.

LORD WILLOUGHBY DE BROKE moved in the House of Lords, on March 16th, that the report of the committee on venereal diseases, appointed by the National Birth Rate Commission,* should be printed and issued as a Parliamentary paper. He recalled that the committee was presided over by the Bishop of Birmingham; that its membership included the heads of most of the religious denominations, and also women doctors and physicians and surgeons of the highest standing; further, that it was appointed with the approval of the Minister of Health.

Having, on behalf of the Society for the Prevention of Venereal Disease, expressed entire concurrence with the view that there should be a national effort to assert the moral obligation of chastity, Lord Willoughby de Broke dealt with a

* BRITISH MEDICAL JOURNAL, February 26th, 1921, p. 314.

passage about self-disinfection, in which the Committee held that no obstacle should be placed in the way of people obtaining the right disinfectants from chemists, and that, if necessary, the law should be altered to enable them to do so. In his opinion it was not really necessary to alter the Act of 1917, except perhaps in the way of making it clearer. In one section of the Act chemists were forbidden to expose or advertise or to recommend any drugs, medicaments, etc., or to hold out any of these things as cures or as preventing venereal disease. At the end of that section there was a paragraph to the effect that nothing in it should apply to what was sanctioned by the public health authority. To carry out the idea of self-disinfection which was visualized by the Committee it would be necessary only that the Ministry of Health should put that section into operation, and should, through the public health authorities, enable chemists to sell to people who asked for such things as were duly authorized. He and others who favoured the policy of self-disinfection did not shut their eyes to other means which might be adopted for combating the evil; but this policy had the advantage that it could be carried out immediately by the efforts of the Ministry of Health. Legislation to make communication of the disease a crime or for compulsory notification would, he reminded the House, in any case be difficult to carry. The official policy here had been to exhort people not to commit fornication, and to tell them if they did they should consult a doctor either before or immediately after symptoms arose. That policy had failed in its object.

The Bishop of London pleaded for a consideration by the Government of the report in its entirety. With regard to the policy of disinfection, he said it was impossible to imagine a greater contrast than was to be found between the evidence of Sir Archdall Reid and that of Colonel Harrison. What he gathered, from his study of the report was that even in the army a system of disinfection was, except under skilled instruction, practically valueless, and that Colonel Harrison, who had hoped for much from the practice, had been grievously disappointed. If that were the case with the army, it would be almost impossible to apply the proposal in the case of civilians. It appeared also, according to his reading of the report, that the fancied security might give rise to greater licence to sin, with the result that the disease might possibly spread. From the moral point of view such a system, he considered, would debauch the conscience of the community. He did not say that any individual should not have the right to purchase disinfectant or cure for any disease from any chemist. He failed to understand, however, how a personal obligation could be enforced without penalties in case of refusal. He agreed broadly, however, that we had reached a stage when strong measures were needed to meet the situation; and it was for that reason he had introduced his bill.

Lord Sydenham, speaking for the National Council for Combating Venereal Diseases, reaffirmed his view that there was no reason to expect any material result if disinfection were tried among the civilian population. Lord Willoughby de Broke apparently wanted the Government to start a propaganda to enforce disinfection upon the population, and his society was making extensive efforts in this direction. Any chemist could, in fact, sell disinfectants now, though he might not advertise them as a specific against the disease. Lord Sydenham agreed that there was no reason why the nature and effects of disinfection, if properly carried out, should be kept secret. But the Government would be ill advised if it issued a statement which might be misunderstood with consequent increase of infection.

Lord Gorell explained why the National Council for Combating Venereal Diseases had been unable to take up an invitation for a joint conference upon the report with the other society and any other bodies desiring to join. The Council could do nothing in any important matter of policy before there had been a general meeting and the conclusions of that meeting had been confirmed by a second. The first meeting was, however, taken place on March 22nd. Points of policy had been, however, unanimously adopted by a representative executive meeting, and had received the full approval of the Ministry of Health. The report of the Bishop of Birmingham's committee, said Lord Gorell, was the work of a private body—a subcommittee of the National Birth Rate Commission—and could not be regarded as official. It was valuable, but not a document upon which lines of policy could be founded. He hoped that the points which his executive had agreed upon might be adopted by his society and prove acceptable to Lord Willoughby de Broke and his society, but it was impossible to prejudge that matter. On the question of immediate self-disinfection he thought that there could be no doubt that, with proper application, in the enormous majority of cases it would be a preventive; but on this subject he wished to quote a letter he had received from a member of the Bishop of Birmingham's committee who had been for twenty-five years a surgeon in the London Lock Hospital and now controlled the venereal department of Charing Cross Hospital. This letter, he thought, showed the grave doubt as to the possibility of any authoritative pronouncement being made at the present time.

Viscount Knutsford, after giving figures with regard to new cases in the London Hospital, urged that it was time for vigorous action undeterred by mere speculative theories as to moral results. If he were Minister of Health he would institute a most energetic propaganda, preaching continence and chastity and pointing out the horrors of the disease in the most awful colours. He would insist on the necessity of self-disinfection; he would emphasize that even disinfection was by no means certain in its action; he would open more clinics. But the

great difficulty with regard to the last was that 40 per cent. of the people who came did not continue the treatment till cured; and that should be made an offence.

The Earl of Malmesbury agreed with Lord Gorell that to publish the evidence of a more or less private committee as a parliamentary paper would be entirely contrary to precedent. But, speaking as a member of the joint committee which investigated the several Criminal Law Amendment Bills, hearing much evidence, he entirely agreed with Lord Knutsford as to the call for action by the Ministry of Health. In Committee he was much more impressed by the evidence of Sir Archdall Reid than by that of Colonel Harrison.

Lord Askwith and the Earl of Clanwilliam supported the views of Lord Willoughby de Broke.

Viscount Peel, Under-Secretary for War, thought sufficient attention had not been paid in the discussion to the report of the Inter-Parliamentary Committee presided over by Lord Astor. That Committee reported unanimously against the advocacy of self-disinfection for the civilian population, and they came to that decision after considering the war experience of the various armies. In regard to promoting a policy for self-disinfection it was desirable, he thought, that they should arrive at some definiteness as to what medical opinion was; but it was very much divided, and action should only be based on some decided preponderance very strongly pointed out by the authorities.

He used in many cases. This would constitute a very grave and serious danger. Besides, there were the moral and social objections to be considered. He could offer no definite information on behalf of the Ministry of Health, but the question was at present receiving. He would shortly receive, the attention of the Cabinet. The report of the Bishop of Birmingham's committee not being official, he could not, on grounds of economy, agree to the request that the Government should publish it.

Lord Willoughby de Broke regarded the reply of Lord Peel as profoundly disappointing. He thought the Ministry of Health might do much to encourage self-disinfection without invoking penalty. As to medical opinion, he said without fear of contradiction that the vast mass of instructed medical opinion in the country was on his side in the matter, and that a preponderance could be claimed in favour of having a cautious, wise, and scientific system of self-disinfection laid down by the Government of the day, vouched for by the proper authority—namely, the Ministry of Health acting through the local health authorities.

The Archbishop of Canterbury hoped it would not be thought that they lacked belief that the subject would be handled in the best possible manner by the Ministry of Health if they did not support the proposal for publishing the report as a Parliamentary paper.

On a division, 9 voted for publication and 29 against.

Criminal Law Amendment Bill.

Upon report on the Criminal Law Amendment Bill in the House of Lords, on March 17th, Lord Dawson of Penn explained why he did not move an amendment which he had put down to qualify Clause 1. This clause reads:

"It shall be no defence to a charge or indictment for an indecent assault on a child or young person under the age of 16 to prove that he or she consented to the act of indecency."

Lord Dawson intended to move that the section should not apply where the child had attained the age of 13 unless the person charged had at the time of the offence attained the age of 18. His object in presenting this amendment was to secure different treatment for youths from that meted out to older offenders, his belief being that in dealing with the younger offenders the law was not dealing with a perverted instinct but rather with the overflow of a natural instinct at a time when restraint was imperfectly developed. He had, however, since framing the amendment had a conversation with representatives of the Home Office who had convinced him that in application the amendment would not have the object he had in view and that it would be more successfully achieved by administrative means. Great discretion was already exercised by chief constables and other authorities, and it was very rare for these young persons to be brought before a court and indicted as criminals. It was held also that the amendment might weaken administrative authority in those few cases amongst young persons which it was desirable should be brought before the justices; hence he did not pursue the matter.

Some drafting amendments have been made, but otherwise the bill passed the report stage as in committee.

Hospital Finance Committee's Report.

In reply to Sir Godfrey Collins, on March 17th, Dr. Addison said that the Committee on Hospital Finances, the substance of whose interim report is given on page 468, hoped to complete the hearing of evidence by the beginning of May, and to present their final report before the end of that month.

Dangerous Drugs Act Regulations.

The Departmental Committee set up by the Home Office to consider what regulations shall be made under the Dangerous Drugs Act has held several meetings under

the chairmanship of Mr. Chester Jones. A paper on the evidence given this week on behalf of the British Medical Association by Dr. Bone and Dr. Cox is printed in the SUPPLEMENT at page 82.

The Parliamentary Medical Committee.

The Parliamentary Medical Committee, which consists of medical members of the House of Commons and university representatives, met on March 21st. Lieut. Colonel Nathan Raw presided. Captain Elliot is honorary secretary of the group. Sir Philip Magnus raised the question of the security of tenure of medical officers of health. He presented a draft bill, and it was agreed that this should be brought up to date and resubmitted at a subsequent meeting. It was further agreed that reports of the proceedings of the Committee should be communicated to the medical newspapers.

A deputation from the Medical-Political Union consisting of Dr. Welford, Dr. Gordon Ward, Dr. Greig and Dr. Peter Macdonald, submitted their views on two matters: (1) The new medical record cards and (2) the new regulations on the transfer of practices and their bearings on the selling value of practices.

The Scottish Board of Health.—Major Glyn asked the Minister of Health, on March 15th, if all instructions drafted by the Ministry of Health regarding forms to be filled in, were invariably submitted to the Scottish Board of Health, or whether the Scottish Board of Health were brought into consultation when such forms were under consideration; and whether, should any difference of opinion arise, the Secretary for Scotland would decide if the desire of the Ministry of Health should apply to Scotland. Dr. Addison replied that the Ministry of Health were not concerned with forms applicable to Scotland except in the case of forms prepared by the Department, of building material supplied, in regard to which the Scottish Board of Health were consulted. The answer to the latter part of the question was in the affirmative.

Medical Staff of the Ministry of Health.—In answer to Sir T. Bennett, on March 16th, Dr. Addison said that the number of whole time and pensionable medical men employed in the Ministry of Health and the Welsh Board of Health was 71.

State Contributions to Health Services.—Mr. T. Thomson asked, on March 16th, whether, in view of the results obtained from the activities of local authorities in the exercise of their powers for the amelioration of the health conditions of their areas, the Minister of Health would see that no curtailment took place in the grants made from the Exchequer in support of school clinics, maternity welfare centres, the care of tuberculous cases and similar work when preparing his estimates for the coming financial year. Dr. Addison replied that the Minister for Education was responsible for the provision of school clinics. As regards the other services mentioned, the amounts inserted in his own estimates for the next financial year were such as were required to provide the State contribution towards existing services and commitments and also for such extension as could be shown to be necessary for immediate and urgent health requirements. Lieut. Colonel Raw asked what grants were made by the Ministry of Health towards the cost of treatment of tuberculosis and what proportion of the total expenditure was represented by the grants. Dr. Addison said that grants amounting approximately to £97,000 would be made during the current financial year towards the expenditure of local authorities on the treatment of tuberculosis. The grants represented less than a farthing in the pound on the total sums voted by Parliament for the supply services of the country. In addition to these maintenance grants, grants in aid of capital expenditure amounting to £36,000 would also be made.

Medical Record Cards.—Asked by Sir W. Davison, on March 16th, the precise composition of the committee set up to deal with medical record cards, Dr. Addison said it was under the chairmanship of Sir Humphry Rolleston, and was composed in all of seventeen persons of whom fourteen were medical men. Of the fourteen medical men on the committee four were in insurance practice at the time, and the fifth had been in such practice until shortly before the committee's appointment. Mr. A. T. Davies asked the Minister of Health, on March 17th, whether large numbers of patients' record cards had been inaccurately filled up by medical men or others; whether the numbers had increased during the past three months; whether he was satisfied with the present method of inspection; and to what he attributed the growth of inaccuracy in these returns. Dr. Addison replied that in the filling up of 15,000,000 cards a certain number of inaccuracies was inevitable, but his information was that the tendency was all in the direction of improvement, and the last part of the question did not therefore arise. The answer to the third part of the question was in the affirmative.

The Bloomsbury Site for London University.—In reply to Sir J. D. Rees, Mr. Chamberlain, on March 16th, said that no decision had been taken on the question of the period during which the Bloomsbury site was to be kept for the new building for London University. The agreement with the vendor contained the clause under which, if before April 1st, 1926, the Government gave notice that they found it impossible to use the property for the purposes of the University, the vendor had an

option to repurchase it for the price given, and if he did not exercise the option the restriction of the use of the site for purposes of the University was removed. During the period of option the property would be administered in its existing form, and in the improbable event of the abandonment of the scheme, it would be for the Government of the day to determine whether to dispose of the site, or to divert it to other purposes.

Veneral Disease on the Rhine.—Captain Elliot asked, on March 16th, whether the Secretary for War was satisfied with the venereal disease admission rate of the army of the Rhine, which showed no reduction from the admission rate as stated by Mr. Churchill in May, 1920; whether this meant that in six years the admissions for venereal disease would have equalled the total strength of the force; and whether every possible effort was being made to reduce the rate, including the spread of information as to self-disinfection. Sir L. Worthington Evans said the incidence of the disease on the Rhine was not satisfactory, and had, indeed, been anxiously considered ever since the area was first occupied. The figures given by Mr. Churchill

The corrected figures now show that in the first quarter of 1920 the rate of disease was 45.81 per 1,000 of the force, and in the last quarter of 1920 was 40.22, and for the month of January last it was equal to a quarterly ratio of 37.80. These figures indicated a gradual improvement. The admission rate included every case admitted to hospital—relapses and readmissions for further treatment, as well as primary infections. Amongst the efforts being made to reduce the amount of disease was the spread of information about self-disinfection as followed in the United Kingdom, where the incidence was now, and was for the year 1920, at a lower level than at any other time in the history of the British Army.

Civil Policy as to Venereal Disease.—Viscountess Astor asked, on March 16th, whether the Minister of Health proposed to depart from the policy of dealing with venereal disease which was adopted by him on the unanimous recommendation of the Interdepartmental Committee which reported last spring after taking full evidence. Dr. Addison replied that the question whether any modification in policy was required was now under consideration, and he was not at present in a position to make a definite statement on the subject. Dr. Targuierson asked if Dr. Addison was aware that the great weight of evidence given before the Interdepartmental Committee and before the Birth Rate Commission was entirely against the idea that prophylaxis for self-disinfection were efficacious means for stopping or preventing venereal disease. Dr. Addison said he believed the statement to be correct, and also that it was supported by the experience of the various armies; but the whole matter was under consideration.

The Disability Pensions New Warrant.—On inquiry by Sir T. Bramston, Mr. Macpherson stated, on March 17th, that in the case of all soldiers whose claim to pensions or grants for services during the war had been dealt with under previous warrants, return to the previous warrant might, if more beneficial to them, be applied with retrospective effect as from September 3rd, 1919. Similar provision was made in the Order in Council dated June 11th, 1920, for seamen and marines. There had been delay in the issue of the Order, but this did not obstruct the process of award.

Neurotic Patients' Treatment.—In reply to Sir Walter de Frece, on March 17th, Mr. Macpherson said that the facilities for the treatment of ex-service neurotic patients had already been greatly extended, and the arrangements made by the Ministry were still in process of development. It would need a prolonged investigation to ascertain the total number of men treated since the formation of the Ministry. The number of officers and men at present under treatment was 9,921.

Blind Welfare Advisory Committee.—Dr. Addison said, in reply to Mr. Myers on March 17th, that the term of service of the members of the advisory committee on the blind expired in December last; that he was proposing to set up a new advisory committee, and hoped to announce its composition very shortly.

Indian Medical Service Travelling Facilities.—Lieut. Colonel Raw asked, on March 16th, when the long promised concessions to officers in the I.M.S. with regard to passages to and from India on duty, would be brought into operation. Mr. Montagu replied that he was not clear as to the reference. Officers proceeding to and from India on duty were granted free passages; possibly Lieut. Colonel Raw was thinking of officers proceeding on leave. In those cases grant of free passages was sanctioned in June last.

Medical Service on River Gunboats in China.—Commander Bellairs asked, on March 17th, whether there was a medical staff of a surgeon and a sick berth attendant to a remaining crew of twelve men in each of our river gunboats in China; whether the First Lord of the Admiralty was aware that the American and French gunboats did not carry doctors, and whether the Board would consider the economy that could be made by relying on the missionary doctors along the river. Sir James Craig replied that the Upper Yangtze had two gunboats with one medical officer and one sick berth rating between them. The Lower Yangtze had eight gunboats with five medical officers and six sick berth ratings. The West River had four gunboats with two medical officers and two sick berth ratings. There was no information as to whether the American or

French gunboats carried medical officers. It was not considered desirable nor practicable to rely on the services of the missionary doctors. The complement of the vessels varied from twenty-five to fifty-three. Owing to the climate and the difficulty of obtaining good vegetables, sickness had to be provided against, as well as the possibility of casualties from local disturbances.

Naval Hospital at Yokohama.—Sir James Craig, in answer to Commander Bellairs, on March 17th, gave the following information as to the British Royal Naval Hospital at Yokohama: Accommodation, 87 patients; Staff, 1 surgeon commander, 4 sick-berth staff and 13 native employees; maximum number of patients under treatment last year 8, minimum number, nil.

Nurses' National Fund.—Mr. John Davison asked, on March 14th, whether the Government had any control over the administration of the Nation's fund for nurses, and whether it was a fact that although one of the main objects of the fund was to benefit nurses who were in precarious circumstances owing to after-war conditions, or were suffering ill health as a result of war strain, out of a total of nearly £150,000 only £2,144 had been applied to this purpose, while nearly £40,000 had been given to the College of Nursing. The Prime Minister replied that the Government had no control over the fund; and he had no knowledge how it was administered. He advised Mr. Davison to direct his inquiries to the Charity Commissioners.

Antimony Treatment for Ex-Service Men.—Captain Thorpe asked the Minister of Pensions, on Monday, whether in view of the successful treatment by antimony of ex-service men who contracted bilharziasis during the late war, he could hold out any hope of similar treatment being at public expense to pensioners who contracted the disease in the South African campaign and were still suffering. Mr. Macpherson replied that the matter was under consideration.

Food in War and Peace.—Mr. Sugden asked the Minister of Health, on March 21st, what steps he was taking to alter the food products instituted in war days as substitutes for a more nourishing type, to protect the physique of the people, especially that of industrial workers and their children, and what action he proposed to take to ensure that local authorities had these matters under close and practical scrutiny. Dr. Addison said he was not sure what particular classes of products Mr. Sugden had in mind. Substitutes such as margarine had generally been adopted by consumers for economic reasons, and so far as he was aware all staple articles of food were now freely available. Local authorities generally had resumed the active enforcement of the Food and Drugs Act, and the information obtained from their reports did not indicate that there was any increase in adulteration.

Artificial Limbs.—Mr. Macpherson informed Mr. Aubrey Herbert, on March 21st, that light metal limbs made by Desoutter were supplied by the Ministry of Pensions when specially recommended by a board of surgeons for reasons which made the supply of this particular limb essential. Where it was considered by the surgeons that another type of limb would be equally satisfactory, the issue of a Desoutter limb was refused on grounds of economy.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on March 8th seventeen cases were considered, and £175 voted to fourteen applicants. The following is a summary of some of the cases relieved:

Widow, aged 60, of M.R.C.S. who died in February, 1921. Applicant's husband had been unable to practise for some time owing to failing eyesight and old age, and the small amount of £60 left at his death from the practice was much reduced by funeral expenses and debts. The widow's sole income is £37 10s., and at present her rent and rates amount to £32 per annum.

Daughter, aged 49, of M.R.C.S. who died in 1873. Applicant was operated on in June, 1920, and since has been living on her small savings and cannot possibly return to nursing, her profession, for some considerable time. She asks for temporary assistance whilst incapacitated.

Widow, aged 44, of L.R.C.P. and S.I. who died in 1918. Applicant was left with two children totally unprovided for, and no income towards the education of the children. This help may cease an allowance, but this help may cease this by letting apartments. Help has been given by the Royal Medical Benevolent Fund and the Professional Classes War Relief Council. Her rent is £48 per annum.

Daughter, aged 65, of M.D. Lond. who died in 1885. Applicant has been doing needlework, but owing to advancing years and the amount of work necessary to pay her rent is now about 18s. a week, and her rent is now about 18s. a week, and her rent is now about 18s. a week.

Daughter, aged 50, of M.R.C.S. who died in 1870. Three sisters live together in one room, one an invalid. Applicant made about £50 this year at nursing, but owing to ill health has applied to the Fund for assistance. The rent of the room is 16s. a week.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1. The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and

skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

THE PREVENTION OF VENEREAL DISEASE.

POLICY OF THE NATIONAL COUNCIL.

IN view of recent events and controversies, the executive of the National Council for Combating Venereal Diseases has drawn up a statement of what it considers should be the general policy of the Council, and this was submitted to the full quarterly meeting of the Council on March 22nd.

It is declared, in the first place, that the public must be officially informed of the prevalence, causes, and consequences of venereal diseases. As by far the most important cause is promiscuous sexual intercourse, the question cannot be dealt with apart from social and moral factors, with regard to which all medical practitioners, parents, and teachers must feel their separate responsibility. Parents must instruct their children, not only in the facts of sex, but in the moral obligations thereby imposed. The action of public health authorities in dwelling in their publications on the medical prevention of these diseases, to the exclusion of moral considerations, is deprecated. The means used to prevent the spread of the diseases must not be such as to weaken the deterrents or have any appearance of condonation. At the same time, the executive recognizes that there are individuals who do not respond to the moral or social appeal, and who may not only contract the diseases themselves but may be a means of infection to others, often innocent persons. In these irresponsible and must be prevented as far as this is possible. The public recommendation, by advertisement or otherwise, of protective disinfectants must result in giving increased notoriety to quack remedies, and is deprecated; while detailed official instructions as to the use of these disinfectants, issued with the sale, will have the appearance, not only of official condonation but of official guarantee to the purchaser against contracting the disease. Further, more, such instructions, unless scrupulously followed after definite and personal tuition, may aggravate rather than prevent. The public should be warned against laxity. On the constructive side, the executive urges that strict personal cleanliness, with information as to the part played by dirt and disease organisms in causing infection of the genital passages, should be inculcated as part of the instruction in sex hygiene. If an individual has incurred, or believes that he (or she) has incurred risk of infection, he must be brought to understand that it is his bounden duty to cleanse himself thoroughly and immediately; delay or inadequacy may lead to development of the disease. If any signs or symptoms, however slight, make their appearance it is his duty to attend promptly at a venereal diseases clinic. It should be officially stated that it is only by fulfilling these duties that the individual can make such amends as are possible for what is a social as well as a moral offence. The existing cleansing and disinfecting centres should be continued experimentally, subject to careful supervision, and any decision as to their extension should depend on the experience obtained. The Ministry of Health, finally, is asked to accept publicly this considered policy as one which is essential to the successful waging of warfare against these diseases in this country.

The statement of policy, of which the above is a summary, was adopted by the National Council.

DR. GEOFFREY LUCAS was entertained to dinner at the Palace Hotel, Aberdeen, on March 17th, by a large and representative gathering of the medical profession and residents of Aberdeen and district and Banchoy, the occasion being his approaching departure from the district, consequent upon his resignation of the post of medical superintendent of the Nordrach-on-Dee Sanatorium, Banchoy, with which institution Dr. Lucas has been associated for the past twelve years. Appreciative speeches were made by Professor Ashley W. Mackintosh of Aberdeen University, Lachlan Mackinnon, Esq., and Provost McHardy of Banchoy. The guest of the evening fittingly responded. On March 19th Dr. Lucas was the recipient of a handsome canteen of silver as a token of esteem and gratitude from his patients at Nordrach-on-Dee.

Scotland.

SCOTTISH BOARD OF HEALTH.

Dr. NORMAN WALKER, Edinburgh, has been appointed chairman of the Scottish Board of Health Consultative Council on Medical and Allied Services, in succession to Principal Sir Donald MacAlister, K.C.B., and Dr. John Yule Mackay, Principal of University College, Dundee, has been appointed vice chairman, in succession to Dr. Walker. While relinquishing the chairmanship of the council, Sir Donald MacAlister will continue to give his services as a member of the council.

THE CAMERON PRIZE.

At a meeting of the University Court of the University of Edinburgh on March 14th, with Principal Sir Alfred Ewing in the chair, it was reported that the Senatus had awarded the Cameron Prize for 1921 to M. Jules Jean Baptiste Vincent Bordet, Director of the Pasteur Institute, Brussels.

THE EDINBURGH TUBERCULOSIS TRUST.

The report presented to the annual general meeting of the Royal Victoria Tuberculosis Trust in Edinburgh stated that the work of establishing a sanatorium colony at Southfield, in the parish of Liberton, was making good progress. The site is within a short distance of Edinburgh and not far from the new chemical laboratories of the University. Sir Robert Philip expressed the hope that the new colony, while affording opportunities for controlling observation, investigation, and research, would result in important contributions to the knowledge of tuberculosis and the most effective means of treating it. Recently persons concerned in the treatment of tuberculosis had been bombarded by inquiries about the Spahlinger treatment, and he had himself received one night a long cablegram from a colonial Government asking what steps should be taken to obtain the benefits of the treatment for patients in the colony. Such an incident and the excitement generally meant hopeless ignorance as to tuberculosis; it was an infectious disease, which took a long time to come, a long time to go, and for which there was no magical cure. The Edinburgh Tuberculosis Trust sought to educate the public, and by establishing a chair of tuberculosis in the University of Edinburgh was endeavouring to ensure that every student of medicine received a thorough training in the subject. The search for a cure would continue, but the public should look with caution on novelties for which more was often claimed than could be fulfilled.

Ireland.

WOUNDED IN HOSPITAL.

In connexion with the representations recently forwarded to the President and Council of the Royal College of Surgeons in Ireland regarding fellows and licentiates of the Royal College and other members of the profession in Ireland affected by the military Order requiring them to furnish daily particulars of wounded persons under their care in hospital, Sir William Wheeler, Vice-President, in the absence, owing to illness, of the President, Mr. E. H. Taylor, has forwarded to the Irish Medical Secretary a copy of the following resolution adopted by the Council of the Royal College of Surgeons in Ireland:

The Council are of opinion that it is contrary to the public interest that medical men should break their professional tradition and, without the consent of their patients, disclose information which they have obtained in the discharge of their professional duties. If any instance is reported to the Council in which one of the fellows or licentiates of the College is pressed to break confidence, such specific case will be considered by the Council, and representations made to the authorities if such be thought necessary.

The pronouncement contained in this resolution will be much appreciated by the profession generally, as there were many professional objections against compliance with the military Order. If the Order were carried out by the profession in Ireland, it would mean that wounded members of the Irish republican army would be disposed rather to die from their wounds than seek medical aid,

when doing so meant for a certainty their trial at a later date by the military authority. This aspect of the working of the military Order caused medical men in Ireland much anxiety, as in practice it would mean the denial of medical aid to the wounded.

POOR LAW MEDICAL OFFICERS' SALARIES.

The Council of the Royal College of Surgeons in Ireland has also had under consideration the non payment of the salaries of Poor Law medical officers in the circumstances stated in this column on February 26th, 1921 (p. 319). The Council appointed Sir William Wheeler, Vice-President of the College, to interview the Local Government Board (Ireland), with the result that he has received from the Vice-President (Sir Henry Robinson) of that body the following letter:

Dear Sir William Wheeler,

In accordance with my promise I write to let you know that the draft Order in Council, which I read to you when you called here yesterday, has been approved by the Privy Council and the order made.

The Order will empower the Local Government Board to authorize boards of guardians and district councils to pay interest on overdrafts which they may require to enable them to meet salaries of medical officers and other urgent payments until they obtain the requisite funds for the purpose from the county councils.

Yours sincerely,
(Sgd.) H. A. ROBINSON.

The Order referred to will not meet the case of the Poor Law medical officers including those retired on pension. The main obstacle to the payment of the salaries of Poor Law medical officers and the pensions of retired Poor Law medical officers is the Malicious Injuries Amendment Act, 1919, and the Restoration of Order in Ireland Act, 1920. These Acts provide that all grants for health and other local administration, as well as all moneys raised through the local rates, are to be set aside to meet awards made for malicious injuries, including those committed by the Crown forces. In connexion with these malicious injuries, Mr. Justice Pim, in his recent address to the Queen's County grand jury, said:

"As to the destruction of property by so-called reprisals, it was a matter for suggestion that it should not be put on the county, but where the destruction was caused by Irishmen it was right Irishmen should bear the burden. It would all end in no county being able to bear what the law would put on."

The last sentence quoted from Mr. Justice Pim's address describes what has happened in the majority of Irish counties; they are not able to meet the burden put on them by recent legislation. The entire machinery of local government administration in Ireland is at present employed, in the first instance, on the collection of the awards for malicious injuries. The result is that the health services are not administered; they are practically suspended, except so far as the local doctors in their charity afford gratuitous attendance to the necessitous poor. Numerous complaints are made that poor persons are dying from want of sufficient medical attendance and medicine. The local authorities, however, disclaim all responsibility; they point out that they have made provision in their rate estimates for this year for the carrying on of health administration and other essential services, but that all the efforts of the Government are directed to compelling the local authorities to continue to lodge their funds with banks as treasurers for the purpose of meeting the awards for malicious injuries by whomsoever committed. The complaint of the Poor Law medical officers and other medical officials, whose salaries are paid out of the rates and public grants, is that recent legislation, in connexion with the disturbed conditions in Ireland, should provide for the seizure of their well earned salaries and their diversion to meet the awards for malicious injuries. Moreover, the amended statutes, which in their application have inflicted such hardships on the Poor Law medical officers and the necessitous poor for whose treatment they were responsible, made special provision that certain public funds set aside in aid of land purchase should be exempted and expended as heretofore. When this legislation was being enacted there were stronger reasons why the public grants and other moneys for Irish health services should be similarly safeguarded, if only in respect for the Red Cross. It is only right to state that the permanent officials of the Irish Local Government Board are not responsible for the present condition of the Irish health services. That Board

had no choice but to administer the local government statutes as they left Westminster. The Chief Secretary for Ireland is the President of the Irish Local Government Board as well as Minister of Health for Ireland. In his dual capacity the Irish medical profession have appealed to him, and based their case more on the grounds of suffering humanity than on their own personal interests. Notwithstanding this appeal the Chief Secretary's attitude is unaltered. The position is this, that fully 30 per cent. of the necessitous Irish people are left by the Government absolutely unprovided for as regards medical treatment and medicine. Such a state of affairs could not have arisen had a Ministry of Health been established in Ireland on the same lines as in England and Scotland.

Correspondence.

PAST APPEARANCES OF ENCEPHALITIS LETHARGICA.

SIR,—So much publicity has naturally been achieved by the recent memorandum of the Ministry of Health on "Encephalitis Lethargica" (Memo. 45 Med.), that it seems desirable that attention should be drawn to the extraordinary inaccuracy of the paragraph thereof which bears the above heading.

1. Willis died in 1675. The allusion, therefore, to a "strange fever" arising in 1685, and described by him, seems "obscure." In 1918 I identified Willis's "epidemic fever" of 1661 as a myoclonic form of "encephalitis lethargica"; Dr. Hamer has identified the "strange fever" of 1658 (following the influenza of that year) as cerebro-spinal meningitis.

2. The "epidemic of somnolence with associated nervous symptoms" recorded by Camerarius in 1712, appears to relate to the account by R. J. Kammermeister of an epidemic febrile catarrh in 1712 that has been hitherto regarded as influenza by every epidemiographer, and which was influenza without doubt. As Kammermeister himself said, during this epidemic, he saw few people who were sleepy unless they had opium. It is to von Economo that must be attached the responsibility for the suggestion that in 1712 one Camerarius described what we now call encephalitis lethargica, as a clinical entity distinct from influenza. In 1729, however, Elias Kammermeister described admirably, as arising during an epidemic of what we now call influenza, an outbreak of myoclonic disease indistinguishable from what is now called encephalitis myoclonica.

3. It is difficult to say what epidemic is indicated by the reference to "Lepecq de la Clôture (1768)," but a careful perusal of the works of the author indicated has failed to satisfy me that, during the "grippe" observed by him in 1768, he noted cases that were "encephalitis lethargica" rather than cerebro-spinal meningitis.

4. By "Ozanam" the Ministry apparently intends reference to Ozanam, the celebrated French epidemiologist, who described much of our modern "influenza" as *fièvre catarrhale*, and so forth. The German prevalences of 1745, the Lyonnais prevalence of 1800, and the Milanese affair of 1802, are all accepted nowadays as parts of the "influenzas" of those years, which he recorded at second-hand.

These facts render even more strange than otherwise would be the case, the statement of the Ministry (loc. cit., p. 8) that no direct relation between encephalitis lethargica and influenza has been established, and the earlier statement of the Ministry's chief medical officer (Annual Report, 1919-20, p. 48) that the pandemic of influenza of 1918-19 was accompanied, in point of time merely, by encephalitis lethargica in various parts of the world. Since a relation in space is not denied, it is difficult to see what other relation than one in time could be expected. What relations other than those of space and time does the Ministry hope to establish by way of "epidemiological connexion"?

As a matter of fact, complete demonstration has been given by me that, during 450 years at least, outbreaks of "epidemic encephalo-myelitis" in many clinical and epidemiological forms have invariably appeared in definite relation to epidemics of influenza.

The demonstration of this fact constitutes practically the only recent advance in our comprehension of influenza; and it is of cardinal importance, for it affords us a means

of foreknowledge of the outbreak of influenza on the grand scale. This was first shown in the Chadwick Lectures for 1918, and later in a paper which was published in the *Proceedings of the Royal Society of Medicine* (Section of History of Medicine) during 1919, and has since been reprinted both at home and abroad and largely copied.

There is no excuse for the appearance in an official memorandum of the inaccurate and loose "historical" references to which I have alluded, for the real historical facts were given in this paper and could have been easily verified.—I am, etc.,

London, W., March 16th.

F. G. CROOKSHANK.

ASTHMA AND ANAPHYLAXIS.

SIR,—Before accepting Mr. Frank Coke's teaching on anaphylaxis as the explanation of asthma (*BRITISH MEDICAL JOURNAL*, March 12th, 1921, p. 372) we must ask if it accounts for all the facts and whether it does not suggest a less complex line of treatment. In the typical picture of anaphylaxis experimentally induced the animal "becomes restless, scratches its muzzle as if irritated; respiration is quickened, then difficult; vomiting takes place, especially in dogs; there is diarrhoea with discharge of blood; micturition occurs; tetanic spasms and somersaults give place to paralysis and collapse; cessation of breathing brings death. There is marked eosinophilia and other blood changes." Of this picture the vomiting and diarrhoea occasionally occur in asthma; the difficult respiration and eosinophilia are regular characteristics. Therefore for asthma anaphylaxis is of interest pathologically, and the results recorded by Mr. Coke show that there is value therapeutically. In short, there is clear evidence of an upset metabolism in asthma; this I have repeatedly tried to point out.

But cannot we go further back, and get to something simpler than anaphylaxis, and especially to something simpler in treatment? The extreme sensitiveness displayed by these patients to minute doses of hundreds of substances harmless to ordinary individuals indicates an extraordinarily unstable metabolism. How is this instability brought about? Is it not likely that it is brought about in a large number of the 50 per cent. who exhibit anaphylaxis in the same way as in the 50 per cent. asthmatics in whom Mr. Coke has been unable to demonstrate anaphylaxis? There is much clinical evidence, supported by therapeutic success, to show that excess of energy food in proportion to energy expended is at the bottom of the condition—be it symptom or disease—called asthma. The mucous membranes become water-laden, plethoric, so that there arise the catarrhal conditions so frequent in children, catarrh of the bronchial tree manifested as recurrent bronchitis; similarly arises catarrh of the skin—eczema. The carbohydrate excess seems to interfere with protein metabolism, and so toxæmia results; to this the intestinal condition contributes. By regulating diet and exercise on these lines we can get the patient cured—to stay cured—in about 70 per cent. of uncomplicated cases.

Again, asthmatic attacks are most frequent between 2 and 4 a.m., and in working men are remarkably common on Sundays and Mondays—week-end asthma. This periodicity there is no gainsaying; and if there is one striking feature about anaphylaxis it is not periodicity.

Yet again, take these five cases from a list of over 600. They are chosen more for because they are all the cases that have come to me since October from the demobilized army, and because the lesson to be drawn is so plain that any one may read.

A., aged 23 (seen in October). Asthma twenty years, except when in the army (three years) and prior to that when at an English boarding-school (two years) where the life was similar in respect of exercise and diet to that in the army. Asthma recurred some months after return to civil life, but has much improved on following proper lines as to diet and exercise.

B., aged 25 (seen August 8th, 1920). Asthma for lifetime, except in the army (four years), and prior to that in English boarding-school (four years). Demobilized eighteen months; first attack March, 1920, then almost weekly, at week-ends. Has remained well since treatment. (A cousin of this man, aged 28, had a very similar history, with the addition of paroxysmal sneezing, the attacks being latterly of markedly week-end type. She became well on turning postwoman during the war.)

C., aged 27 (seen in October, 1920). Asthma twenty-two years, except in the army while in the infantry. On getting a commission and a "soft job" he had recurrence. Reports now "Very well, have had no attacks."

D., aged 24 (seen in October, 1920). Asthma twenty-two years, except in the army (three and a half years) and once just after armistice. Three months well after demobilization, then recurrence, chiefly at week-ends. Asthma now much better, but there are still occasional attacks.

E., aged 32 (seen March 8th, 1921). Asthma six years—that is, two years before entering army. None while in army (three years); fortnightly since (mostly week-end; Mondays and Tuesdays off work).

These cases will all get well and remain well as long as they properly apportion diet and exercise, especially open-air exercise, and take care as to the cooking and eating of their food. If comment is necessary, it is contained in the story of the following case:

A Salvation Army officer, aged 47, was sent to me in July, 1916. Asthma thirty years, except seven out of eleven years in Canada. While there he visited an Indian location. An old squaw said to him, "You breathe heavy." "Yes; I have asthma." "Ah, you English eat too much." "What would you have me do?" She held up two fingers. "Two days no eating." As before his telling me this story I had advised a weekly fasting day, he was so struck by the advice that he followed it. He came to see me in June, 1920, and said, "I've not been out of bed one night for three years; for two years while in France I had no asthma, though I slept in the open in the wet and mud. I can bring on asthma by an indiscretion in diet, and as I'm travelling about the world living mostly in hotels I cannot control my diet, but just leave certain things alone"—mainly a matter of cookery—"but I fast on Fridays and stick to my weekly blue pill."

Similar cases, multiplied to weariness, could be adduced from civil life, all pointing the same lesson. What is wanted is research as to the metabolism in asthma, such research as has been carried out, especially in America, as regards kidney conditions and glycosuria, and probably no disease would prove more illuminating on many problems in metabolism.—I am, etc.,

JAMES ADAM, M.A., M.D.,

Surgeon for Diseases of Ear, Nose and Throat,
Royal Infirmary, Glasgow.

March 18th.

THE CURE OF HAEMORRHOIDS WITHOUT OPERATION.

SIR,—In the interesting correspondence on this subject I have as yet seen no mention of the curative properties of electricity. Many patients fear operation or cannot, for reasons of general health, undergo either operation or any procedure involving pain. Every electro-therapist sees so many patients who exclaim, "Why did no one tell me of this method of treatment years ago?" that they are only beginning to realize how little it is known by the profession at large.

Patients who have suffered for ten and sixteen years with constant bleeding, with pain which is rarely absent, are, after ten to twenty applications of the local high frequency current, relieved of pain and bleeding. Where pruritus and eczema accompany the haemorrhoids the relief in the majority of the cases is almost magical; a week of daily ten-minute treatments giving more progress than months—in some cases years—of ointments and lotions. At the same time the patient remarks that the treatment has a very tonic effect upon the general health, so that the termination of the period of treatment is regretted. Any remaining piles can be dealt with by electrolysis, which is painful, probably as much so as the method of injection.

I feel that an apology is due for taking up your valuable space by the mention of a matter so well known to all electro-therapists, but the fact that several practitioners have told me that they had never heard of this method of treatment must be my excuse.—I am, etc.,

London, W., March 12th.

AGNES SAVILL, M.D.

PUERPERAL INFECTION.

SIR,—I have been much interested and rather amused at the many articles on this subject wherein our learned professors give most elaborate advice, etc., as to the manner in which the medical man should clothe and disinfect himself when attending a midwifery case, but they fail to state that the majority of cases of puerperal infection are due to bad nursing and dirty habits on the part of certain so-called monthly nurses (Mother Gamps), and whom the medical attendant scarcely ever appears to trouble about after having performed what he considers to be his own part of the work, and leaving the house when everything appears to be satisfactory, not waiting to

see if the patient is properly washed and that all dirty clothing and slops are at once removed from the bedroom.

How is it that some medical men have more cases of puerperal fever in their practices than others, although most careful about disinfecting themselves, etc.? I have ventured to supply the answer. I have seen nurses throw dirty diapers under the bed of the patient, also the chamber filled with discharges, etc., and who did not intend removing them for some hours after unless forced to do so. I have known a nurse, after disinfectants had been previously used, pour water into a lately used chamber pot in order to wash the patient's private parts, and when remonstrated with, reply, "Oh, I have been a nurse for many years, have attended the best families, and you are the only doctor who has ever told me it was wrong."

As a medical man who has attended many cases of midwifery, I would venture to suggest the following simple recommendations, but which, of course, would not be applicable to either trained nurses or those who understand the importance of sanitary conditions, namely:

1. Do not leave the patient for at least half an hour after the placenta has been removed, and see that the nurse uses a proper vessel containing the clean water with disinfectants to wash the perineum, etc.

2. If the nurse is a novice at the work, do it yourself and show her the correct way.

3. See that all soiled clothes, diapers, and slops are immediately removed from the bedroom and do not allow them to be thrown under the bed, only to be removed later on (a very common occurrence). There is very little fear of puerperal fever if these instructions are thoroughly carried out and the medical attendant takes the necessary antiseptic precautions about himself.—I am, etc.,

Bristol, March 15th.

W. HOWARD CORY, M.R.C.S. Eng.

THE CONTROL OF BILHARZIA: DESTRUCTION OF MOLLUSCS.

SIR,—It has been suggested that wild birds should be employed to lessen the incidence of bilharzia infection, because they are known to feed on fresh-water snails. The Public Health Department was recently considering the desirability of introducing others into the stream at Pinetown, Natal, for a similar reason. The destruction of these species of fresh-water snail which harbour schistosomes, more especially *Physopsis africana*, *Limnaea natalensis*, *Planorbis Pfeifferi*, *Isidora forskali*, *Isidora tropica*, *Isidora schackoi* and *Modiolus capensis* should certainly be attempted in those places which show evidences of stream pollution; but to eradicate fresh water snails from any country would seriously disturb the balance of nature in many regions because of the number of organisms that depend upon the snail for food. Our attention should rather be directed to those places where artificial dams have tended to increase the number of fresh-water snails and other evidences of stream pollution. A few domesticated duck will soon rid such artificial collections of water from fresh-water snails. A pool at Sydenham, from which I used to collect hundreds of infested snails in 1919, has been kept free from them for twelve months, as a result of the Indian to whom the pool belongs introducing three domesticated ducks on my advice. Besides *S. boris*, some of the schistosomes that infest these snails probably infest animals, and the introduction of water animals is only likely to increase the number of infested snails. Domesticated duck soon eat up all the snails without introducing others to take their place; but, in providing snails as food for wild-bird life, nature has safeguarded the extermination of the snails by providing that, when visiting a pool in search of snails for food, the wild birds should carry in the clay attached to their claws minute snails and snails' eggs. Wild birds thus assist in the spread of bilharzia infection.—I am, etc.,

Durban, Natal, Feb. 17th.

F. G. CAWSTON, M.D. Cantab.

BIBLIOGRAPHICAL REFERENCES.

SIR,—In the JOURNAL of March 19th Dr. W. C. Rivers criticizes my book on *Pulmonary Tuberculosis in General Practice* (Cassell and Co., 1916), on the ground that one-third of the bibliography refers to the writings of Scotsmen—an offence in itself—and that there are no references to original German or Austrian papers. In attributing these

blemishes to political and geographical prejudice he is right, but in ascribing these prejudices to me he is wrong. As stated in the preface, the book was written during 1914-15 in a warship. This ship was cruising between Sierra Leone and the mouth of the Amazon, and in that part of the South Atlantic Ocean there are no reference libraries, this being a deplorable fact for which I am in no way responsible. Had there been access to a library I would have quoted in certain instances the original German authorities. On the other hand, the book makes no pretence to be a compilation of the writings of others, and as there are only fifty-five references in a work of over 100,000 words, the proportion of Scotsmen quoted should cause no undue anxiety.—I am, etc.,

London, S.W., March 19th.

HALLIDAY SUTHERLAND.

IRRITABLE BLADDER.

SIR,—Many learned and interesting papers have appeared lately on retention of urine arising from prostatic hypertrophy with residual urine. But for every one such case that a practitioner is consulted about, there are at least twenty who ask his advice on irritable bladder where there is no question of residual urine, only a feeling that when the desire comes to micturate the patient must at once do so or wet himself, and then he passes about six ounces only. These cases are most troublesome at night, and afflict most men of over 60 or 65. Women are not exempt, as most old ladies say they have to get up at night two or three times. Cold, various beverages, such as tea and coffee, alcohol in all forms, but especially spirits, increase the discomfort. In the majority of cases I cannot find anything in the urine to account for the trouble.

I can find no help in treatment from the published textbooks; in fact, I cannot see anything new stated from what was taught half a century ago; therefore I appeal to specialists and fellow practitioners to aid me if they can.

I do not think the prostate has much to do with the trouble, otherwise why should females suffer? I inquired last week of an old patient who had had the prostate removed about ten years ago—a very successful operation, in so far that he can urinate freely and retain the urine about four hours in the daytime; but he informs me he has to get up to pass water two or three times a night.—I am, etc.,

London, S.W., March 20th.

JAMES HAMILTON, M.B.

ANGIO-NEUROTIC OEDEMA.

SIR,—I have read with great interest Dr. Truman's communication on angio-neurotic oedema, published in the *BRITISH MEDICAL JOURNAL* of January 15th, 1921.

In the *JOURNAL* of April 3rd, 1915, to which Dr. Truman refers, I gave notes of two cases of the disease, in one of which I was the sufferer. I have not been able to follow up the other case, as the patient left British Honduras for England soon after my article was published. I have, however, heard that he suffered from repeated attacks of the complaint, and that he was strongly advised by the doctors in England not to return to the colony. He subsequently died in England, but I have not been able to ascertain the cause of his death.

My own case, which was a very severe and typical attack, I have no doubt whatsoever was brought about by several factors, all acting together and at the same time. For two weeks I was camping in the forest exposed to rain and sun, with insufficient and poor food, and subjected to innumerable bites from mosquitos, ticks, sand-flies, and a species of the *Tabanidae* family, whose bite was particularly bad, producing great local inflammatory swelling and oedema. The climax, however, was reached in my return journey when I passed a night in a "bush" house. Here I was at the mercy of thousands of bed-bugs, and these pests attacked me so fiercely and in such numbers that sleep was absolutely out of the question. A few days after my return to comfort and civilization I experienced my first and only attack of angio-neurotic oedema.

I most sincerely hope that Dr. Truman may be mistaken in his view that the disease always returns. My one and only attack was in the year 1913, and up to the present

time I have been free. The disease is uncommon in the colony, and I have seen no other cases.—I am, etc.,

F. L. DAVIS, M.R.C.S.

Corozal, British Honduras, February 18th.

SPINA BIFIDA.

SIR,—Mr. Cokkinis, in your issue of March 12th, records an unusual case of myelocoele, and in the concluding paragraph of his communication states that an exceptionally busy practitioner has had but two cases of spina bifida in thirty years.

In these circumstances it may be of interest to record that between November 19th, 1919, and February 25th, 1921, I have had 4 cases of spina bifida occurring in about 100 midwifery cases; 3 of them were born dead, the other lived for two months.—I am, etc.,

R. P. SMALLWOOD, M.B., B.Ch.Cantab.

Little Waltham, Chelmsford, March 14th.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Radcliffe Travelling Fellowship.—The Master and Fellows of University College announce that the Radcliffe Trustees have elected Tom Sydney Nelson, M.A., B.M., University College, to a Radcliffe Travelling Fellowship of £200 for three years.

Radcliffe Prize.—The Master and Fellows of University College have awarded a Radcliffe Prize of £50 to Edward Palmer Poulton, M.A., D.M., F.R.C.P., Balliol College, for his researches in Physiology and Pathology.

UNIVERSITY OF CAMBRIDGE.

THE degree of Doctor of Laws *honoris causa* will be conferred upon H.R.H. the Prince of Wales on May 31st.

The election to the Sir William Dunn Professorship of Biochemistry will be held on April 19th.

The General Board of Studies has recommended the appointment for five years of a University Lecturer in Physics as applied to Medical Radiology in connexion with the Special Board for Medicine.

At a congregation held on March 11th the following medical degrees were conferred:

M.D.—Geoffrey Evans, R. R. Walker.

M.B., B.Ch.—E. P. Brockman.

M.B.—R. K. Merson.

Applications for the John Lucas Walker Studentship in Pathology must reach the Professor of Pathology, at the Pathological Laboratory, before April 5th.

UNIVERSITY OF LONDON.

The University of I

As announced last week,

of December 15th last to close the University at the end of July. At the meeting of March 16th a resolution was adopted to continue the laboratory until the end of the current triennium—that is to say, until the end of 1923.

At a meeting on March 15th the Faculty of Medicine adopted two resolutions: the first stated the Faculty's opinion that the closure of the Physiological Laboratory, South Kensington, would be a grave injury to the advancement of science, and the second affirmed that it was highly desirable to continue the work of the Physiological Laboratory in its present situation on its pre-war condition until at least equivalent facilities can be provided elsewhere, as forming a valuable part of the work of the University.

QUEEN'S UNIVERSITY, BELFAST.

At the graduation ceremony held on March 19th the following degrees were conferred:

M.D.—J. Donnelly, F. Hopkins.

M.B., B.Ch., B.A.O.—J. A. Smyth, Eileen O. Bartley, H. A. Thompson, J. Black, S. M. Bolton, J. W. Bradbury, Henrietta Bradshaw, P. F. Connolly, M. Emery, J. English, J. Gausson, E. M. Hadden, H. Harris, S. M. Kirk, D. Loughridge, R. J. McMullan, B. McNeill, A. McSparran, E. C. Patter-on, J. Patton, J. D. Reynolds, W. J. Simpson, A. C. Sinclair, Kathleen R. Snodgrass, J. Young.

D.P.H.—J. M. Clearkin, J. H. Davison, J. W. Kernohan, Orla R. I. Love, J. A. Martin, G. Patton, W. Sanderson, R. L. Sinclair, S. J. Stewart.

* First-class honours. † Second-class honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Nominations for Councillors.

MONDAY, March 21st, was the last day on which the names of candidates for the elections for members of Council on July 7th were to be received. No fewer than eleven nominations have been received. Of the four retiring candidates, Sir George Makins and Mr. Ernest Lane will not seek re-election. On the other hand, Mr. Waring, of St. Bartholomew's Hospital, Fellow 1891, Member 1893, and Mr. F. T. Burghard, C.B.,

Fellow 1889, Member 1886, will once more offer their services to the Council. The new applicants are: Mr. W. Thelwall Thomas, M.B.E., of Liverpool, Fellow 1890, Member 1886; Mr. A. H. Cheate of King's College Hospital, Fellow 1892, Member 1888; Mr. J. H. Fisher, St. Thomas's, Fellow 1893, Member 1891; Mr. W. Turner, Westminster, Fellow 1895, Member 1893; Mr. C. H. Fagge, Guy's, Fellow 1895, Member 1896; Dr. Victor Bonney, Middlesex, Fellow 1899, Member 1895; Mr. L. Bathe Rawling, St. Bartholomew's, Fellow 1900, Member 1896; Mr. Donald J. Armour, C.M.G., West London Hospital, Fellow 1900, Member 1897; and Mr. Russell Howard, C.B.E., London Hospital, Member and Fellow in 1903.

Obituary.

WILLIAM IRONSIDE BRUCE, M.D. ABERD.

Physician in Charge of the X-Ray Departments, Charing Cross Hospital and the Hospital for Sick Children.

We regret to announce that Dr. William Ironside Bruce died at his residence in London on Monday, March 21st, after a severe and distressing illness of about two months' duration. His early death has cut short a career of good service and much usefulness, and his loss will be greatly felt by many members of the medical profession, and is especially lamented by Charing Cross Hospital and its Medical School.

William Ironside Bruce was the second son of the late Dr. William Bruce of Dingwall, and a nephew of Dr. J. Mitchell Bruce, Consulting Physician to Charing Cross Hospital. His mother, who survives, was a Miss Ironside, so that he was a cousin of Major-General Sir W. E. Ironside, now on service in Mesopotamia. His family had its origin in the upland Aberdeenshire parish of Keig, in the valley of the Don, which remained remote from outside influences till comparatively recently. The lads of promise passed from the parish schools of the district to the grammar schools in Aberdeen and to the University, and it is along this well-beaten road that men with names such as Bruce, Ironside, and Robertson Nicoll have proceeded to take their place in the nation's roll of honour.

William Ironside Bruce was born at Dingwall, and was educated at various schools in the north-east of Scotland. Entering the University of Aberdeen he obtained the degrees of M.B. and Ch.B. in 1900, and then he took service as civil surgeon in the South African Field Force. During his period of service he suffered from enteric fever, the consequences of which affected his health for some time. While in South Africa he took much interest in the early application of x rays for the diagnosis of war injuries. On his return to this country he obtained the diploma of Public Health, and proceeded to the degree of M.D. of his university. Shortly afterwards it became necessary to appoint an assistant to the late Sir J. Mackenzie Davidson at Charing Cross Hospital, and Ironside Bruce was selected for this post. He remained in the service of Charing Cross Hospital to the time of his death, and gradually built up an exceedingly complete and efficient x-ray department in the hospital.

Ironside Bruce was intensely interested in his work, in the scientific developments of his subject, and especially in its practical application to the diagnosis and treatment of disease. The whole of his later work was built on a good foundation, as is evidenced by the publication in the early part of his career of his *System of Radiography with Atlas of the Normal*. He was a good teacher, and many now engaged in the practice of radiography owe much to his instruction. Perhaps Ironside Bruce's strongest point was his desire to be of service to his professional brethren in their practice. With a very complete knowledge of his subject he had a sound and increasing acquaintance with general medicine and surgery. Anyone who had the opportunity of consulting him, either in hospital or in private practice, gained not only such knowledge as was possible by radiographic means but much sound information both as to diagnosis and treatment. In this peculiar relationship Bruce's work was of the greatest value to all his friends. In process of time he became President of the Section of Radiology in the Royal Society of Medicine, and took much interest in the establishment of the special diploma in this subject, now given by the University of Cambridge. It is only a fortnight ago that we announced his appointment to be President of the Section of Radiology and Electro-therapeutics at the forthcoming Annual Meeting of the British Medical Association at Newcastle.

For some months his colleagues had been unhappy as to the condition of his health, but his energy would not be restrained. At the beginning of the year, however, he was persuaded to stop work and take a prolonged holiday. Shortly it was found that his illness was serious. Blood examination established the diagnosis of the severest type of aplastic anaemia, and from this disease he died. The evidence now accumulating that this condition can be caused by the effects produced on the blood-forming structures of the body by the more penetrating radiations both from x-ray tubes and from radium renders it almost certain that he succumbed as the result of his continuous and enthusiastic work in the subject of his choice.

THE LATE CAPTAIN E. R. ARMSTRONG.—Major-General Sir Patrick Hehir, I.M.S. (ret.), writes: I should deem it a privilege to be allowed to add a few remarks to those made in the issue of the BRITISH MEDICAL JOURNAL of March 19th, 1921, regarding the late Captain Edward Raudolph Armstrong, I.M.S., whose untimely death has deprived the Indian Medical Service of one of its most brilliant and capable officers. I knew him chiefly at Army Headquarters in India, where he was attached to the D.M.S.'s office, and did most excellent work during the war. He was very loyal to his friends and those with whom he was officially connected. He had a lovable disposition, and I personally greatly enjoyed and benefited by his friendship. It was a source of pleasure to him to be of service to others. He was very hard working, and got through an extraordinary amount of work with exceptional ease. Nothing seemed to deprive him of his calm, quiet, and unflustered demeanour: he appeared to grasp intuitively the main points of any subject he was dealing with; one looked upon his power of penetration as a remarkable gift, and found him a quick and sound thinker and rapid worker. I was principally brought into contact with him in sanitary matters, and found that he had a natural talent to get down to the first principles of questions arising and apply the remedy. He was a good mathematician. One expected him to go far, but there was always doubt as to his being able to stand the strain of the high pressure at which he worked. One of his greatest griefs was that his state of health precluded his selection for field service during the great war.

Medical News.

At the meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on Monday, April 4th, at 8.30 p.m., papers on malaria will be read by Dr. W. Broughton-Alcock and Dr. H. C. Lucey.

THE Tuberculosis Society proposes to arrange a post-graduate course in Paris towards the end of May if a sufficient number of applications are received by Dr. W. G. Dickenson, 1, Bidley Villas, Newcastle-on-Tyne.

A SERIES of meetings for graduates, with demonstration of cases, will be held by Dr. Dingwall Fordyce in Ward 4, the Royal Liverpool Children's Hospital, Myrtle Street, at 10 a.m. on the following Saturdays: April 2nd, baby feeding and the prevention of disease; May 7th, indigestion in infancy, the wasting baby; June 4th, diet of older children, indigestion; July 2nd, dietetic treatment in illness.

At the meeting of the Harveian Society held at the Paddington Town Hall on March 17th the Harveian Lecture was delivered by Dr. Leonard Williams on "The thymus gland in everyday life." At the close of the lecture a vote of thanks was proposed by Dr. Willcox and seconded by Dr. Wilson.

A VERY successful reunion dinner of No. 14 General Hospital, B.E.F. (Wimereux), was held on March 16th at the V.A.D. Ladies' Club, 28, Cavendish Square. Lieutenant-General Sir John Goodwin, D.G.A.M.S., a former commanding officer of the hospital, was in the chair, and proposed the only toast, "Absent Friends." Apologies for absence were read from Colonel R. J. C. Thompson, Major Colin Mackenzie, and others, and a message was sent from the reunion to Miss Fox, matron during the greater part of the hospital's existence, who was now abroad. Among those present at the large gathering were Miss Barrett, R.R.C., Miss Morris, R.R.C., and other former nursing sisters; Lady Elizabeth Keppel, the Hon. Cecilia Lawley, Miss Sloggett, and many other former members of

the V.A.D. detachment; and Lord Dawson of Penn, Colonel A. Webb-Johnson, Colonel Francis Steward, Major Hugh Thursfield, Captain Sir Joseph Skevington, Captain Ridley Mackenzie, and other former medical officers.

THE twenty-fifth anniversary of the day on which Professor Röntgen made his first communication on the discovery of x rays to the Würzburg Medical Society was recently celebrated at the Physical Institute of Würzburg University.

THE personal estate in the United Kingdom of Lieut.-General Sir William Babbie, V.C., K.C.B., K.C.M.G., was £6,807.

TWO supplementary volumes of Keen's *Surgery*, which have been in preparation since the armistice, will shortly be published by Messrs. W. B. Saunders. The first six volumes recorded the progress of surgery down to 1913; the two new volumes bring it down to 1921.

THE annual meeting of the Société française d'oto-rhino-laryngologie will be held in Paris at the Hôtel des Sciences Savantes, 8, Rue Danton, on May 9th, 1921.

THE International Congress on the History of Medicine will be held in Paris at the Faculty of Medicine from July 1st to 5th, 1921. In connexion with the Congress, a historical exhibition is being organized. Communications should be addressed to the Secretary, Dr. Laignel-Lavastine, 10, Place de Laborde, Paris.

IN January 7 cases of rabies occurred in Holland—6 in the province of Groningen and 1 in the province of Drenthe.

THE 5th Sicilian Medical Congress, consisting of three sections devoted to medicine, surgery, and professional interests respectively, will be held next month at Palermo.

THE forty-fifth meeting of the German Society of Surgery will be held in the Langenbeck-Virchow House, Berlin, from March 30th to April 2nd.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London. MANAGER
2. FINANCIAL (Advertisements, etc.), telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, telephone, 2630, Gerrard. The address of British Medical Association is 16, South F telegrams: *Bacillus*, Dublin; telephone, the Scottish Office, 6, Rutland Square, Associate, Edinburgh; telephone, 4361, Central.

QUERIES AND ANSWERS.

"J. T." asks for light on the nature of the aches commonly called rheumatism, chronic rheumatism, or muscular rheumatism, and often associated with a coming change in the weather.

PROLONGED ADMINISTRATION OF ARSENIC.

"L. H." asks whether the long administration of arsenic, given fairly regularly over a period of three years in a case of psoriasis, which it greatly benefits?

INCOME TAX.

"N. R. W.," who contemplates retiring to England from the Colonies, inquires what tax he would pay on "a private income of over £2,000"?

Our correspondent would pay as income tax nothing on £135 (or on £225 if married), 3s. on £225 and 6s. on the remainder—less appreciable allowances for children under 16 years of age and for payment of life assurance premiums. He would also be liable to pay supertax at 1s. 6d. in the £ on the excess of his income over £2,000.

"G. P." intends to relinquish his practice, owing to illness and to commence a small consulting practice in the neighbourhood. He asks, "If the expenses exceeded the gross earnings, could the loss be set against the private income?"

* Yes; but if that is done the amount of the loss cannot be carried forward as a minus quantity for the average of future years. We may add that "G. P." might anticipate some difficulty with the authorities over his expenses—for example, the total cost of car and chauffeur might be objected to if infrequently used for the practice.

"ANOTHER R.M.O." receives "a salary of £350 plus £150 in lieu of board and lodging." He asks if the £150 is assessable.

* Yes—as our correspondent does not receive "in kind" but in cash. The principle is that something received for services rendered is assessable if it is money or something capable of being converted into money.

"A. K." pays interest on a bank overdraft. He asks whether he can deduct the amount in arriving at his total income.

* In our opinion, yes, provided of course that the amount has not been treated as a professional expense, in which case the deduction has already been effected in that the amount assessable has been reduced. Perhaps our correspondent can induce the inspector of taxes to quote the precise section of the 1920-21 Finance Act on which he relies for support in refusing the claim; we cannot identify it.

LETTERS, NOTES, ETC.

ADRENALINE IN RESUSCITATION.

DR. A. E. YOUNG (Kuruman, Bechuanaland) writes: I read with interest Mr. J. P. Lockhart-Mummery's note in your issue of January 15th, p. 100, on adrenaline in resuscitation. It has left me rather confused, as I have been taught that adrenaline with chloroform forms a poisonous compound which is liable to cause—and has caused—fatalities, and that its use during or just after chloroform anaesthesia is contra-indicated. I should be glad to learn from any of your readers whether the facts are as I have stated, or that I am under a misapprehension.

A THREE-WHEELED RUNABOUT.

THE Cambro monocar is a runabout produced by the Central Aircraft Company (60, Chancery Lane, W.C.2) with a view to combining the comfort and protection from weather of a three-wheeled car with the simplicity and economy of a motor tricycle. The body is something of the nature of a large side-car, with a hood and a small glass screen. Behind the body and above the driving wheel is a 2 h.p. horizontal engine with twin opposed cylinders. The transmission is direct from the engine through a counter-shaft to the back wheel by chains. The engine is started by means of a foot lever. The system of springing used on the machine is new, rubber cords as in aeroplanes being utilized for absorbing road shocks. Several of these monocars are stated to have travelled over 6,000 miles; it is said that they will average sixteen miles an hour, can do twenty-six when required, will climb any ordinary hill, and will run 100 miles on a gallon of petrol. It would seem that the Cambro monocar, like a motor scooter, might prove useful as an additional mode of locomotion in some rural and suburban practices. It is as cheap as a motor cycle, and affords a great deal more protection from weather.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line...	0	1	6
Whole single column (three columns to page) ...	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so made. Advertisements should be delivered, addressed to the Manager, at least later than the first post on Tuesday morning, and, if not paid for at the time, should be enclosed.

NOTE.—It is the rule of the Post Office to receive postal telegrams addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

373 Acute Endocarditis in Children.

LEDFORD (*Amer. Journ. of Diseases of Children*, February, 1921) analyses 250 hospital cases of acute endocarditis in children from the point of view of etiology, symptoms, signs, treatment, and results. Seventy were "mild" cases, the remaining 180 being classed as "severe." Several patients gave a history of tonsillitis, or chorea, or both, in addition to rheumatic fever, and the endocarditis occurring with chorea was found to be much milder than that occurring in either rheumatic fever or tonsillitis. Endocarditis in childhood is largely due to rheumatic fever, and it may be the first manifestation of the infection and be very severe in type with the mildest articular signs. Although 41 per cent. did not complain of any cardiac symptoms the most constant were dyspnoea, precordial pain, palpitation, and epigastric pain. Temperature averaged 99.8°. The leucocyte count was much higher in the severe cases and was not influenced by age or degree of fever. The mitral valve was always affected, the aortic being much less frequently involved (namely, 37 instances). The earlier in childhood the primary endocarditis occurs the better is the ultimate prognosis, though the immediate prognosis is much worse in younger children. The duration of the fever is significant, an early permanent return to normal being most favourable, since a long duration of fever means greater cardiac distress. Treatment mainly consists of rest in bed as flat as possible consistent with comfort. Severe cases were not allowed even to feed themselves, such strict rest not being relaxed until every sign of the acute infection had subsided, mild cases averaging 30.5 days in bed and severe cases 50 days. Any local foci of infection (for example, in teeth or tonsils) were removed before the patient was discharged from hospital.

375. The Predisposing Causes of Sciatica

LINDSTEDT (*Acta Medica Scandinavica*, January 14th, 1921) was induced to study the static factors promoting sciatica by seeing a patient whose sciatica he associated with an inflammatory pes planus. He then collected from various hospitals in Stockholm 100 cases in which the diagnosis of sciatica had been made by independent observers. Thus there was no bias in the diagnosis. In no less than 91 cases important morbid conditions were found, and they were calculated, in the author's opinion, to favour the development of sciatica. In 14 cases there were disorders of the knee joint, in 12 a history of rheumatoid arthritis, in 11 disorders of the hip joint, in 8 considerable varicose dilatation of the veins, in 8 disease of the spine, such as spondylitis deformans or fracture, in 8 pronounced pes planus, in 5 traumatic lesions of the foot, and in 4 marked looseness of the knee joint with genu recurvatum. Other complications were tumours, salpingitis, fracture of the femur, pronounced genu valgum, deformities of the foot, and constitutional static weakness. In 7 cases the complications were of gonorrhoeal origin. The author gives the following arguments in favour of regarding these complications as causative and not merely coincidental: Whenever they were unilateral they occurred on the same side as the sciatica. The complications were too numerous to be merely coincidental, and many of them were of a noteworthy and comparatively rare type. Sciatic neuralgia due to these causes may be compared with trigeminal neuralgia following toothache or the muscular fatigue induced by presbyopia.

375 Bronchopulmonary Spirochaetosis (Castellani)

LEVI (*New York Med. Journ.*, January 29th, 1921) discusses the three types of bronchopulmonary spirochaetosis first described by Castellani. An acute attack is usually accompanied by chilliness and fever, and lasts for from two to eight days. The cough is pronounced, with scanty mucopurulent sputum rarely containing blood, and rheumatoid general pains may be complained of. A subacute attack lasts from two to several weeks with little or no fever, frequent cough, and the expectoration of pink, jelly like mucus. The physical signs are those of a simple bronchitis. Chronic broncho spirochaetosis may follow on either of the above, or have a slow, insidious onset. The symptoms are those of a chronic bronchitis, but at times the sputum may contain blood

for two or three days together. Diagnosis depends upon the result of microscopic examination of the sputum collected after the mouth has been well rinsed out with sterile water, or some antiseptic, in order to remove the possibility of contamination by spirochaetes from a pyorrhoea. The similarity of the symptoms to those of malaria, influenza, and pulmonary tuberculosis makes differential diagnosis at times difficult. Acute symptoms usually disappear after a few days in bed, and in the way of specific treatment arsenic gives better results than any other drug, and considerable success has attended the intravenous use of one of the arsphenamine products. A more careful study of the sputum in chronic cough would possibly bring to light other cases of the disease, since the spirochaete has been found in thirty nine cases out of seventy nine examined.

376. Treatment of Migraine

DURAND (*Bull. Soc. de Ther.*, January 12th, 1921) reports the case of a woman who, at the age of 50, began to suffer from attacks of migraine accompanied by urticaria. The attacks became worse in the course of six months, until she had only a few days' relief at a time. After all other methods had failed, Durand had recourse to autohaemotherapy, which he had found successful in several cases of urticaria. A subcutaneous injection of 10 c cm. of the patient's blood was made during an attack, and four days later the dose was repeated at the onset of an attack, with the result that for the first time for three months the patient was a fortnight without another attack. The next attack was mild, and the following milder still. During the following months only abortive attacks occurred, and were easily cured by subcutaneous injections of 2 c cm. of the patient's blood.

377 The Date of Onset of Epilepsy.

KLESSENS (*Nederl. Tijdschr. v. Geneesk.*, November 6th, 1920) brings forward statistics which show that both forms of epilepsy start more frequently at certain definite periods of life than at others. All investigators have found that epilepsy commences most frequently in the first year, about the sixth year, and in the twelfth year. Some observers have also noted a slight increase of frequency at the eighteenth year. On the other hand, there is a considerably smaller number of cases beginning in the fourth year, and the diminution after the eighteenth year is very pronounced. While symptomatic epilepsy regularly declines in frequency after the first year, the diminution in the frequency of the genuine form is more marked after the sixth year, and still more so after the eleventh year. Klessens suggests that the difference in the time of onset may help to distinguish genuine from symptomatic epilepsy.

378 Perforation in Typhoid Fever

APCANGELI (*Riv. Osped.*, December 15th, 1920) still believes that the best treatment for typhoid is the cold bath and ice, and under his routine method says his mortality is not more than 24 to 3 per cent. The chief causes of death are haemorrhage and perforation, hence the great importance of early diagnosis and prompt surgical treatment in perforation. Perforation is not confined to severe cases, although more likely to occur where there is much haemorrhage, but it may happen to an ambulatory case. The three cardinal signs are vomiting, pain, and abdominal rigidity. When there is reason to fear perforation it is well to relieve meteorism by passing a rectal sound, limiting the food, and controlling peristalsis by opium. In patients too ill to notice a sudden onset of pain, tenderness in the right iliac fossa may suggest the possibility of perforation. Very small perforations with hardly any escape of faecal matter, but plenty of gas, may give rise to difficulty in diagnosis. In simple meteorism without perforation, the initial stab of pain, the localized tenderness, and the abdominal rigidity are wanting, other possible sources of error are appendicitis, scybala giving rise to colic in convalescence, cholecystitis (the pain in these cases is in the upper half of the abdomen, where perforation is rare), renal colic, attero mesenteric duodenal occlusion, and hysterical mimicry; the author quotes cases illustrating these varieties. He also refers to a specific urine reaction recently described by Sgambati as pathognomonic of acute peritonitis. Absence of liver dullness, lowering of

temperature, rapidity of pulse, are useful aids in diagnosis, but all come late and are not certain signs. It is better to do a laparotomy without perforation than leave a perforation without a laparotomy. Brown's stethoscopic sign (hearing a fine crepitant r  le in the right iliac fossa) and observation of the position of the patient are too fleeting in duration to be of much value.

379. Subcutaneous Emphysema in Measles.

BERGOLIA (*Il Morgagni*, September 30th, 1920) discusses at some length the conditions associated with subcutaneous emphysema, and describes the case of a child aged 1½ years, suffering from measles and bronchopneumonia, who on the fourth day of the disease developed subcutaneous emphysema, extending to the supraclavicular fossae and to the face (excluding the chin) up to the zygomatic arch, and spreading the next day to the trunk. There was a certain amount of cyanosis and dyspnoea. The emphysema did not clear until the twenty-sixth day; the child died. The cough was at no time violent. The author has collected 31 cases of subcutaneous emphysema complicating measles, and 13 of these died (6 also had bronchopneumonia). He speaks highly of the diagnostic value of the stethoscope in discovering and delimiting the area affected by emphysema. A bibliography of thirty references is appended.

380. Spontaneous Recovery from Renal Tuberculosis.

IN 1913 Harbitz published twelve cases showing that, contrary to the established teaching, tuberculosis of the kidney may run a chronic, benign course terminating in caseation with fibrosis. In five of his cases there was complete or partial obstruction of the ureter, which was either converted into a solid fibrous band or was distended by caseous matter. Two further examples of spontaneous recovery from renal tuberculosis are reported from Harbitz's pathological department by his assistant SCH  NNING (*Med. Rev.*, January, 1921), who discusses at length the different criteria by which clinicians and pathologists decide whether tuberculosis is active, latent, or "cured." As both cases terminated fatally with chronic nephritis, and amyloid disease was demonstrable in one case, the author insists that the proof that spontaneous recovery occurs in renal tuberculosis does not warrant the abandonment of operative treatment. He is also of the opinion that cases of spontaneous recovery are comparatively rare, and that in these rare cases the term "recovery" should be used with reserve.

381. The Mental Condition in Paralysis Agitans.

ACCORDING to CLAUDE (*Paris m  d.*, October 2nd, 1920), in most cases of paralysis agitans there are no mental disturbances, properly so-called. The patients merely present a certain slowness of ideation, more or less pronounced depression, and a tendency to melancholy—symptoms which can be explained by the patients' consciousness of their distressing condition. Claude records three cases illustrating, first, the resemblance between certain mental disturbances following lethargic encephalitis and those of paralysis agitans; secondly, the rapid variability of the mental symptoms met with in these two diseases, in which the same subject is very apt to show a quick change from a state of depression to one of merriment and excitement. Claude is of opinion that the mental disorders of paralysis agitans are the expression of a disturbance of function of the cerebral cortex and of certain lesions of the motor centres which adapt speech to thought. Lethargic encephalitis, in which the anatomical lesions are the same as in paralysis agitans, produces the same motor and psychical syndrome as the chronic vascular changes which appear to be the origin of paralysis agitans.

382. Scorbutic Dysergy.

ABELS (*Wien. Klin. Woch.*, October 7th, 1920) states that this term has been given to the diminished resistance of the scorbutic organism to protect itself against infections. This is illustrated clinically by the frequency of gingivitis, round carious teeth, the obstinate furunculosis and the extraordinary liability to bronchitis and bronchopneumonia shown by scorbutic patients, as well as by their increased susceptibility and diminished resistance with regard to specific infectious diseases. This diminished resistance is also seen in experimental animals. Intracutaneous injections of staphylococcal cultures to which, as to all pyogenic organisms, normal guinea-pigs are extremely resistant, produced a distinctly haemorrhagic infiltration and an abscess in scorbutic guinea-pigs, whereas these phenomena were entirely absent in animals fed on a diet containing antiscorbutic vitamins.

SURGERY.

383. Operative Treatment for Cancer of the Breast.

BRATTSTR  M (*Acta Chirurgica Scandinavica*, December 11th, 1920) has investigated the after-histories of patients operated on for cancer of the breast between 1898 and 1915. He experienced great difficulty in tracing these cases, and of the total of 295 patients who survived the operation, 39 could not be traced. As there was no record of their deaths in the parish registers scrutinized, a large proportion of these must be regarded as recoveries. In 136 cases the patients had subsequently died from recurrence of the disease, and in 45 cases there were signs of recurrence. In 75 cases the patients were either still free from recurrence or had died of other diseases than cancer more than three years after the operation. In as many as 22 of these 75 recoveries, metastases were found in the axillary glands at the time of operation, as shown by microscopic examination. The author refers to isolated cases of local recurrence followed by a second operation, radium treatment, and complete recovery. One patient who was operated on in 1911 showed a local recurrence in 1914; she underwent radium treatment and was quite well when examined in 1919, except for a couple of enlarged glands in the supraclavicular fossa. Included among these cases of malignant disease of the breast were 15 of sarcoma; 5 of these patients were still living and well six to seven years after the operation. The author gives details of several cases of special interest, because either simultaneously with the cancer of the breast, or at some later period, they showed primary tumours of other organs.

384. Nerve Stretching in Chronic Ulcers of the Legs.

VOLKMAN (*Zentralbl. f. Chir.*, February 12th, 1921) has treated 12 patients by the method of nerve stretching first introduced by French surgeons twenty-five years ago for the treatment of perforating ulcer, and later by Bardescu and Chipault for ulcers of the legs. In each case the ulcers had been present for a long time (twenty-seven years to two months) and various methods had been tried without any obvious improvement. Three of the patients were men and nine women, the ulcers being in seven cases on the right leg and in five on the left leg. The area of the internal saphenous nerve was most frequently affected, and in all cases this was the nerve stretched. When the outer side of the leg was affected, the area of the external saphenous nerve was involved, when the lesion was deeply situated, the superficial peroneal, and in circular ulcers that of the medial cutaneous nerve. In elderly persons the operation was performed under spinal anaesthesia, and in younger persons under a local anaesthetic. Of the 12 cases 9 were cured, 1 was discharged improved, and 2 were still under treatment. The operation was in most cases followed by an immediate improvement. All the patients were given the same ointment before and after the operation, and were kept strictly in bed.

385. Renal Calculi in Soldiers.

GAUTHIER (*Journ. d'Urol.*, October, 1920), who was formerly in charge of an army urological centre, states that among 918 cases in hospital or the out-patient department he diagnosed calculi in 10 cases and suspected their presence in another 10 cases. The diagnosis was most difficult in cases of aseptic lithiasis, in which there was no pus to suggest the presence of calculi, and where the stones were small and often composed of urates. Gauthier classifies his cases in two groups: The first consisted of four patients with aseptic calculi, who were placed in the auxiliary service owing to the frequency of renal colic. The second group consisted of six cases of infected lithiasis, in one of which he performed nephrolithotomy, in four nephrectomy, and in one partial excision of a very adherent pyonephrotic sac. The cases of infected lithiasis put up with their pyuria for a long period, probably owing to the slight degree of involvement of the bladder. One patient who had phosphatic calculi, the total weight of which was 104 grams, was able to serve in Macedonia for fifteen months. There was a great difference in this respect between these cases and patients with renal tuberculosis, who soon reported sick owing to early cystitis. All the cases on whom an operation was performed were recommended for discharge from the army, especially as three at least had slight lesions in the opposite kidney. In three cases discharge from the army or service in the auxiliary forces was recommended on account of pyelonephritis, verified by catheterization of the ureters.

386 Diagnosis of Gastric Ulcer.
HARDISTY (*Canadian Med. Assoc. Journ.*, January, 1921), reviewing the several means of diagnosis in gastric ulcer, shows that no single means by itself is pathognomonic, but a careful study of all the conditions together is necessary to arrive at a conclusion. In addition to a careful clinical examination very great importance attaches to an accurately weighed history. An account of the pain and its remissions, the vomiting and bleeding, and the downward progress, when considered with x ray findings, will generally confirm the diagnosis. Pain and tenderness are constant symptoms, and although hyperacidity is generally thought to be fairly constant in gastric ulcer, in many cases the acid may be normal or even subnormal. The finding of occult blood in the faeces probably indicates the presence of a gastric ulcer, though its absence does not exclude the possibility. The barium meal and x ray findings, with simultaneous palpation of the stomach while the patient is screened, are useful, though some cases of gastric ulcer show no x ray changes.

387 Gangrene of Erectile Tissue
ACCORDING TO VINET (*Journ d'Urol*, October, 1920), gangrene of erectile tissue may assume the following clinical forms. (1) The commonest is gangrene of the corpus spongiosum, which is responsible for circumscribed or more frequently diffuse perineurthral inflammation and is favoured by hyperaemia and coagulation of blood within the fibrous coats of the corpus spongiosum. (2) Gangrene of the corpus cavernosum on one or both sides is rare, and is usually a complication of urinary phlegmon, to the symptoms of which it adds pseudo pyrapism and rapid septic aemia, or a slower but often fatal pyaemia. (3) Gangrene of the glans may be a complication of the preceding form, but is usually the result of a cutaneous lesion. (4) Fulminating gangrene of erectile tissue is usually the result of an initial thrombosis. It must not be confused with the spontaneous fulminating gangrene of the external genitals described by Fournier, which is superficial. The general condition is little affected in spite of the intensity of the lesions. The starting point may be a focus of perineurthral or prostatic infection.

388 Intestinal Tuberculosis
CAIRD (*Edin. Med. Journ.*, February, 1921), from a study of 43 consecutive cases of intestinal tuberculosis, concludes that tubercle is a common affection of the intestinal tract, either as an acute destructive or as a chronic formative type. The former is the more usual and is secondary to pulmonary phthisis from direct infection by swallowed sputum. Characterized by extensive intestinal ulcerative lesions, with diarrhoea, it becomes a manifestation of advanced phthisis, and is rapidly fatal. The chronic formative type is less common, and infection occurs through the blood or lymph stream, giving rise to localized hyperplastic structures causing obstruction and necessitating operative treatment. There may be little or no pulmonary mischief. The lesions in both types are usually at the ileo caecal region, the appendix and lymph glands being involved. Tuberculous nodules develop in the submucous and subserous layers and give rise to ulceration, perforation, or the formation of faecal fistulae; but in the second type perforation is rare on account of the great proliferation of connective tissue. Definite symptoms may not arise for some time until signs of obstruction occur. Diagnosis may be difficult, but the chronicity of the ailment and the family and personal history of tubercle may help, though cases with a relatively short history cannot easily be discriminated from subacute appendicitis, while in others malignancy is simulated. Treatment aims at free and complete resection of the affected area, generally including the ileo caecal region, but there is not the same need for removal of all enlarged glands as in carcinoma. Short circuiting should be reserved to overcome destruction when excision is impracticable. The mortality after lateral anastomosis is not so great as that after excision, but it should not replace the latter unless the condition of the patient precludes it.

389 Mastoiditis and Pott's Disease
 It might be thought that there could be but little difficulty in differentiating between mastoiditis and Pott's disease. **PORTMANN** (*Rev. de Chir.*, September, October, November, 1919) in an exhaustive study shows how error can be avoided. The difficulty is only likely to arise when the inner wall of the mastoid gives way and pus collects in what Portmann calls the "cranio cervical gutter." The differential diagnosis of inflammation in this area with and without abscess and sinus formation is fully discussed. Recognition of Portmann's principles should obviate all possibility of mistake.

OBSTETRICS AND GYNAECOLOGY.

390 Late Results of Hysterectomy for Cancer of Cervix.

SCHWITZITZ (*Zentralbl. f. Gynäk.*, March 5th, 1921) records the after history of 41 cases of corporeal and 231 cases of cervical cancer treated by the Wertheim Zweifel abdomino vaginal operation, with a primary mortality of 4.7 per cent. It was possible to trace the after history of all the cases, 177 in number, of cervical cancer operated on from 1910 to 1915, of these, 12 had died immediately after operation, and 92 had remained free from recurrence for at least five years. The remainder (77) had died from intercurrent disease (2 cases), or had shown recurrence of the malignant condition (75). Recurrences took place in the first year in 46 per cent. of fatal cases, during the first three years in 85.1 per cent.; in three cases only was recurrence observed after the fifth year. Turning to prognosis as based on the condition of the pelvic glands at operation, Schwitzitz reports that unilateral enlargement was encountered in 97 cases, of these, the glands were removed in 52, with 26 cases of lasting (five years) cure. Bilaterally enlarged glands were removed in 35 cases, of which 13 showed no recurrence. Two among seven cases, in which enlarged glands were left *in situ* remained cured after five years. Only 53.6 per cent. of the enlarged glands removed were found on microscopical examination to be carcinomatous; five patients from whom such carcinomatous glands were removed were found to be healthy five to ten years after operation. Allowance being made for the primary mortality, the percentages of lasting cure obtained by the unmodified Wertheim operation and by the Wertheim Zweifel technique are given as 54.5 and 46.5 respectively.

391. Maternal Mortality in Childbirth

PUNDY (*Med. Journ. of Australia*, January 15th, 1921) gives some interesting statistics on maternal mortality. He compares the figures for 1911-14, which were 4 per 1,030 in England, with those of New South Wales, which were 7 per 1,000 for the same period. In both, one third of the deaths were due to puerperal fever. He considers that the remedy for this high mortality is a greater supervision of midwives by means of a Midwives Act, which is at present lacking in Australia, and by making puerperal sepsis a notifiable disease. He points out that of recent years the practice of midwifery has been passing more and more into the hands of midwives, and that the medical practitioner is becoming more and more a consultant as far as childbirth is concerned. He quotes Williamson (British Medical Association Annual Meeting, Cambridge, 1920) to the effect that obstetrics is essentially a branch of preventive medicine, and that the dangers of childbirth are to a great extent preventable.

392. Placenta Praevia.

GONZALES (*Semana Med.*, 1920, xxvi) records 8 cases of placenta praevia, with severe haemorrhage, treated by a vaginal Caesarean section, which he still regards as preferable to the abdominal method. There was no maternal mortality and of the children one only (who weighed just under 8½ lb.) died.

PATHOLOGY.

393. Studies in Properties of Blood Platelets

The increasing difficulty in obtaining brilliant cresyl blue led **BUCKMAN** and **HALLISEY** (*Journ. Amer. Med. Assoc.*, February 12th, 1921) to search for another dye that might be used for the vital staining of blood. After experimenting with a large number of dyes, they finally adopted as the most satisfactory, easily procurable vital stain crystal violet—pentamethyl pararosaniline hydrochloride. This dye, like brilliant cresyl blue, stains the leucocytes deep blue. The platelets and the reticular substance of young erythrocytes, which also are stained blue by brilliant cresyl blue, are stained a deep lilac by crystal violet. Haemoglobin is stained but faintly. The percentages of reticulated cells in twenty nine different cases counted by Robertson's method, using both brilliant cresyl blue and crystal violet, were substantially the same in every case. In fresh preparations a rough estimate also may be obtained of the number of platelets satisfactorily with crystal violet as with brilliant cresyl blue preparations. A method for the counting of platelets is described which it is asserted is superior to other methods.

The blood is collected in a miniature transfusion tube and is diluted to the 101 mark with a fluid containing 6 grams glucose and 0.4 gram sodium citrate dissolved in 100 c.cm. of distilled water. To this are then added about 0.02 gram tolucene red—dimethyldiamidotoluphenazine—sometimes also called "neutral red," and 0.1 gram of crystal violet. The solution is gently heated to 60° C., and held at that temperature for five minutes. It is allowed to cool slowly to room temperature, and centrifuged for ten minutes at 2,000 revolutions a minute. The supernatant liquid is then filtered twice, each time through three thicknesses of No. 30 Whatman filter paper (dry). The solution is preserved by adding 0.2 c.cm. of formaldehyde solution, and then keeps indefinitely. The method yields counts generally slightly higher than those obtained by the other methods, and especially so when the number of platelets is great. By this method simultaneous determination of platelets, red cells, and white cells may be made. It gives results for all three of the formed elements of the blood which closely parallel those obtained by standard methods.

394. Studies in Cyanosis.

LUNDGAARD (*Acta Medica Scandinavica*, January 14th, 1921) has measured the O₂ and CO₂ content of the venous blood of about 100 persons, some of whom were cyanosed. He could find no relation between the CO₂ content of the blood and the cyanosis present, nor between the cyanosis and the absolute O₂ content of the venous blood. On the other hand, he succeeded in proving the existence of an increased quantity of non-oxidized haemoglobin in the venous blood of cyanosed persons. In normal persons the non-oxidized quantity of haemoglobin was, on the average, 5.5 volumes per cent., varying from 2 to 9 volumes per cent. In cyanosed persons, on the other hand, these figures ranged from 8 to 20 per cent. It was not possible to establish any definite relation between the severity of the cyanosis and the quantity of non-oxidized haemoglobin. The author concludes that cyanosis is caused by an increase of the amount of reduced haemoglobin in the blood, and that the threshold at which cyanosis appears is 6 or 7 volumes per cent. By the measurement of the amount of non-oxidized haemoglobin in the blood of persons with cyanosis important conclusions can be drawn as to the degree of oxidation in the lungs, and the effect of oxygen inhalation and venesection in cyanosed persons can be studied. The author's results have been described in the *Journal of* . . . 1918, vol. xxxiii, p. 1.

395. Primary Tumour of the Pleura.

Du BRAY and ROSSEN (*Arch. Int. Med.*, December 15th, 1920) report a case of these very rare tumours. Apart from occasional benign tumours, such as lipomas, fibromas, and chondromas, true malignant neoplasms originating in the pleura are divided into sarcomas and endotheliomas. The authors call their tumour a "mesothelioma." At autopsy it was found to fill the left pleural cavity, invading the left lung and pericardium, extending through the diaphragm and extensively invading the omentum, with superficial invasion of the spleen and liver. Small nodules of implantation occurred all over the peritoneum. Microscopically the cell type and manner of growth was variable, apparently depending on the environment. In places where no hampering influence was at work the cells were of medium size, spherical in shape, with a homogeneous eosinophilic cytoplasm, a relatively large round vesicular nucleus and small faint nucleoli. This type was found specially in lymphatic vessels. Where the cells were grouped together they assumed the appearance of epithelial growths. At other parts the cells were isolated and diffused through the connective tissue, and then were more like fibroblasts. Occasionally multinucleated masses were found. Though admitting that the tumour was too far advanced to determine definitely its point of origin, the authors consider that as the tumour growth was distributed over the costal pleura so diffusely it arose from this surface and secondarily involved the visceral pleura and the adjacent lung. In view of the fact that it did not possess the general characteristics of endotheliomas arising from lymphatics and blood vessels, Du Bray and Rosson prefer to label it a mesothelioma arising from the lining mesothelium of the pleura. It ought to be pointed out that there are no general characteristics of endotheliomas on which pathologists are agreed—in fact, the term endothelioma is generally avoided by the best authorities. There is nothing in this case, nor, indeed, in any of the so called primary tumours of the pleura, to convince one that the tumour did not originate from the alveolar epithelium of the lung itself.

396. Bacteriology of Dysentery.

KIRSCHNER and SEGALI (*Wien. klin. Woch.*, December 23rd, 1920) record their bacteriological investigations during an outbreak of dysentery in Vienna in the summer of 1920. The first examinations which were made on stools sent to the laboratory had a very unsatisfactory result, as out of 178 specimens only 11, or 6 per cent., showed dysentery bacilli. The writers therefore decided to visit the hospital and examine the stools directly after they were passed, with the result that out of 487 specimens 189, or 39 per cent., were positive. Finally, 86 specimens were obtained by rectoscopy, and 56 of these, or 65 per cent., were positive. The epidemic showed a by no means uniform etiology, for of the 256 positive specimens 120 showed bacilli of the toxic group (Shiga-Kruse type), 124 bacilli of the mannite-fermenting type (Flexner, Strong, and Y types), and 12 bacilli of the Schmitz type.

397. The Occurrence of Spirochaetes in the Urine in Secondary Syphilis.

FISSINGER and HUBER (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 17th, 1921) remark that it is very easy to mistake the various forms of spirochaetes found in the meatus and terminal portion of the urethra in the male, and still more frequently in the female, for the *Treponema pallidum*. In persons with long foreskins a large quantity of spirilla are present, mostly belonging to the type of *Spirochaeta refringens*, though other groups may also be found, such as *Treponema minutum* and *Treponema callygrym*. Careful washing of the glans and meatus with boiled water and permanganate, reception of the urine from the middle of micturition in a sterile test tube, centrifugalization and immediate examinations are necessary precautions. Lévy and Guilhé examined the urine in 24 cases of syphilis at different periods of the secondary stage, and in only one case, in which two typical treponemata were present, was the result positive. In 13 cases examined by Fissinger and Huber the results were always negative with one exception. The writers conclude that *Treponema pallidum* may be excreted in the urine in exceptional cases in secondary syphilis, but that the investigation requires a careful technique. The presence of the organism may be associated with a normal renal function (Lévy and Guilhé), severe syphilitic nephritis (E. Hoffmann), or slight albuminuria with a rise of Ambard's constant, as in the writers' case.

398. Adenoma Sebaceum and Renal Tumours.

CRUTCHFIELD (*Arch. Derm. and Syph.*, September, 1920) reports a case which may be classed with those from time to time reported showing the curious association of adenoma sebaceum with various congenital tumours. In this instance the patient was a married woman of 27 who had had from her childhood numerous small nodules of adenoma sebaceum on each side of the nose, on the cheeks, and on the forehead. An acute illness set in with high temperature and rapid pulse, nausea and vomiting, and continuous pain in the left side. The left nictur continued much blood. A tumour mass extended from the costal margin to the pelvic brim. The patient died, and on post-mortem examination there was found a large tumour of the left kidney adherent to the diaphragm and lumbar muscles. Microscopically it consisted of smooth muscle, fat, and larger areas of sarcoma—in short a teratoma of the kidney.

Blood Cultures in Bubonic Plague.

399. THEISSIER, TANON, GASTINEL, and REILLY (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 17th, 1921) examined the blood of 20 patients admitted to the Claude Bernard Hospital with buboes supposed to be due to plague, and obtained the following results: (1) In 8 cases in which the other laboratory tests were simultaneously negative the blood cultures were also sterile. (2) Of 12 cases in which the diagnosis of plague was established bacteriologically, namely, by presence of Yersin's bacillus in the pus or serum of the glands, inoculation into mice and cultures from the glands, the blood cultures remained sterile in 3, and in 9 were positive. The writers, from a study of their cases, came to the following conclusions: (1) The presence of Yersin's bacillus in the blood is the rule during the first days of the disease. (2) The mildest forms may be associated with bacillaemia. (3) The bacillaemia present in the mild forms of bubonic plague must be distinguished from the primary or secondary plague septicaemia which is the rule in grave forms with multiple visceral lesions. (4) Cultivation of the blood is a valuable addition to the bacteriological diagnosis of plague.

standing say 22 feet (the height above the ground of the highest of the stones in the figure), without machinery, would require an association of effort never previously called forth by human activity. The remarkable and famous alignment—or series of alignments—in Brittany, a plan of which is reproduced on the right, extends for several miles, in three groups. The first consists of 1169 standing stones in eleven lines, the second of 982 stones in ten lines, and the third of 540 stones in thirteen lines. A short distance to the north is another group in ten lines with 1129 stones. The megaliths, colossal at the beginning (one is 63 ft. high and 14 ft. in diameter), gradually diminish in size until they measure sometimes less than 3 ft. at the ends of the avenues. It is clear that these imposing monuments served some purpose which their builders deeply felt to be worth the painful labour involved, but what that purpose was still remains to be discovered. It is considered that all the alignments of the present illustrations were erected at the same period, *i.e.*, towards the close of the Neolithic.

CULTURE PHASE: NEOLITHIC

MEGALITHIC MONUMENTS (2): EARLIEST EVIDENCE OF UNITED AND ORGANISED LABOUR.

The accompanying illustrations indicate that the people who first began to build stone monuments that have endured to the present day, must have been pioneers in organising disciplined bands of workers for carrying out undertakings requiring the co-operation of hundreds—and even thousands—of men. To move a colossal stone weighing many tons and

A British Medical Association Lecture ON THE TREATMENT OF FRACTURES.*

BY
S. ALWYN SMITH, O.B.E., D.S.O., CH.M.EDIN.,
F.R.C.S.EDIN..

SURGEON, ROYAL HANMADYD SEAMEN'S HOSPITAL AND PRINCE
OF WALES HOSPITAL, CARDIFF; CONSULTING SURGEON,
MINISTRY OF PENSIONS, WILSH REGION.

PRIOR to the war, of the three schools of thought as to the treatment of fractures each had adherents, but the school which advised and practised operative fixation appeared to be gaining favour at the expense of the less spectacular treatments of conservative immobilization and mobilization with massage. In certain cases results by either method left much to be desired.

The diversity of opinion, and oftentimes the poor results, led the British Medical Association to appoint a committee to report on the merits and demerits of treatment by operation or by splinting.¹ One of the conclusions reached by this committee was as follows:

"For surgeons and practitioners who are unable to avail themselves of the operative method the non-operative procedures are likely to remain for some time yet the more safe and serviceable."

This conclusion obviously favoured the operative method, and the general practitioner was left in doubt whether he was justified in treating his own fractures or whether he was to hand them over to the surgeon at the nearest hospital.

During the war most members of the profession had ample opportunity of treating compound fractures, or at any rate of seeing the results of such cases treated by conservative means where this treatment was standardized according to the ideas of the Liverpool orthopaedic school, with modifications such as are exemplified by the work of Pearson, Sinclair, and others. Conservative treatment by splinting has thus again come into its own purely on account of the excellent results gained by standardized methods in thousands of gunshot compound fractures obviously unsuitable for operative fixation of fragments.

In the early days of the war some surgeons tried the effect of plating septic compound fractures, in the hope that the good effect of immobilization of the broken ends would outweigh the ill effects of interference and the inclusion of foreign material. This effort was short-lived, and rightly so, as the results were universally bad.

I mention the various methods of treatment in order to emphasize the fact that in treating fractures in civil life, which are for the most part simple fractures, we should not be hidebound adherents of a single method. Where our experience tells us that we cannot get a good functional result by splinting alone we should be prepared to operate, provided we have experience in that method also. The main essential is that, following general principles guiding treatment, we shall pay the strictest attention to detail in whatever method we adopt. I was closely associated with Sir Robert Jones for seven years, and am imbued with his principles and follow his methods, therefore I am biased towards conservatism in treatment. The advent of radiography has educated the profession as to the shortcomings of accurate fragmental apposition in conservatism, but in addition it has falsely educated the laity. Patients see their x-ray plates showing firmly united fractures in good alignment, with good functional result, but because the fragments are not meticulously apposed they deem themselves the victims of malpraxis, and strained relations may ensue. The public will in time, no doubt, become educated to the axiom that it is not possible to either guarantee accurate anatomical reposition by mechanical means or perfect function by operative methods.

The principles laid down by H. O. Thomas and Sir Robert Jones in the mechanical treatment of fractures are important and have a direct bearing on successful outcome.

1. A fracture is a potential deformity and must be regarded as such. By treatment the potentiality must be prevented from becoming a reality.

* Delivered before the East Hertfordshire Division, December 15th, 1920.

2. Strong, steady, fixed extension, with corresponding counter-extension is required as distinguished from forcible intermittent pull succeeded by a period of muscular relaxation. This principle is applicable more especially to fractures of the lower extremity, particularly the shaft of the femur. It is held that a steady traction through a Thomas bed splint, with the counter-extension of the ring of the splint against the tuber ischii, is preferable to the inclined bed and weight-and-pulley method. The latter, though theoretically constant in pull, is practically intermittent when the patient moves up and down the bed, on account of the friction of the limb against the subjacent mattress.

3. Correct alignment in conjunction with obliteration of shortening. A reduction which is incomplete at the primary operation can easily be made complete within the next few days by merely continuing and increasing the extension. The correction is brought about by fixed extension combined with appropriately fixed pads to overcome lateral deviation. This combination may also require the lower end of the fragment to be approximated to the upper by altering the position of the limb.

4. Avoid rigid circular compression which tends to produce ischaemia. In this regard the use of plaster-of-Paris as a primary dressing is dangerous except in the hands of experts. Splints should be shaped to the contour of the limb. Concavo-convex metal splints are the most favoured. They can be bent or twisted at will to produce the desired effect. They must be of greater width than the limb to be immobilized so that the circulation shall not be impeded.

5. Union may be delayed; this is sometimes unavoidable, but there is a vast difference between delayed union and non-union. When union is slow, it is of great importance to leave the limb alone and not repeatedly to move the fragments to see how things are progressing. Thomas laid down the rule that the rest must be prolonged and absolute. Idle curiosity may be instrumental in converting a delayed union into a non-union.

6. Union of a fracture does not imply its consolidation. Bones which appear firm on palpation or manual pressure will, after many weeks, yield to the body weight.

MAL-UNION AND NON-UNION.

Both mal-union and non-union are common occurrences and are often related. Angular deformities should not occur; even if we cannot produce an end-to-end apposition by traction and splinting there should be no difficulty in securing correct alignment. This is of great importance in the lower limb.

The Commonest Types of Mal-union.

In fractures of the neck of the femur the angle between neck and shaft is reduced and a condition of *coxa vara* results. Where the fracture is in the upper third of the shaft the upper fragment is abducted, the lower fragment pulled up to the inner side of the upper one, and a shortened bowed femur results. In fractures of the middle of the shaft there is a concavity forwards instead of the normal convexity, and *genu recurvatum* is afterwards found to be present. The same thing happens where the injury is in the lower fourth of the shaft. Here the upper end of the lower fragment lies behind the lower end of the upper one, and the lower fragment may even point almost directly backwards.

Fractures in the upper third of the leg may lead to a high bow leg (Fig. 1). Fractures of the middle third may result in knock-knee with either inversion or eversion of the foot, and fractures of the lower third of both bones generally end with a valgoid deformity of the foot with an internal rotation. The deformity of a malunited Pott's fracture is familiar to us all, and it is very often a shock to the surgeon who treated the case, as the deformity may arise after the patient has left his care.

Deviation from correct alignment means, in accordance with Wolff's law, alteration in structures—that is to say,

FIG. 1.—High bow leg after fracture of the upper third of the femur.

the internal architecture of the bone changes in response to new forces of strain and muscular stress that the bone itself is called upon to stand. It also means that aberrant forces are thrown on to the joints above and below, and this, combined with deviated lines of muscle pull, will result in chronic pain and discomfort, and traumatic arthritis may result. This traumatic arthritis may be the forerunner of hypertrophic rheumatoid changes in the involved joints.

Even end-to-end apposition of fragments may result in malunion where slight lateral or antero-posterior deviation causes faulty deflection of body weight.

THE COMMONEST CAUSES OF MALUNION.

1. *Being too Sparing with Traction.*

It is useless to be ladylike with a fracture in a strong muscular man, especially of femur or tibia. Traction with a pulley should be begun before the splint is applied, and we should not be satisfied until the affected side is of equal length with the other, even if continued and over-increasing traction in the splint for a few days is found to be necessary. If the bones are of equal length there cannot be much overlap and no lateral deviation. In recent fractures of the lower extremity pulleys are rarely needed except in the very muscular. Preliminary traction by means of a roller towel clove-litched round the limb, counter-extension being obtained by another roller towel round the perineum and fixed to the leg of the table at the head end, is generally sufficient. In cases of older standing, not firmly united, a three-ply or five-ply pulley may be requisitioned. Here the counter extension must be of stronger material. To prepare for such cases ring bolts should be let into the wall at each end of the operating room at a height of about 3 ft. Where union is complete an oblique osteotomy is performed at the site of malunion, and I am accustomed to get primary extension by means of a steel drill through the lower end of the involved bone, sterilized steel wires are attached to it, and the other ends are looped through the pulley hook.

It is surprising what strain can be obtained by this means, and I have successfully reduced a shortening of 3 in. at one sitting without damage to soft parts where the fracture was of six months' standing.

2. *Inefficient Splinting.*

The splint should allow continuous extension in the correct line for the obviation of deformity, and it should control the joint above and below the fracture. Where bones are naturally curved, as the shaft of the tibia, this curve must be imitated in fractures of both bones of the leg by laterally pulling bandages and pads. If the leg is set absolutely straight, an everted ankle and a strained internal lateral ligament of the knee will result when the patient begins to walk.

3. *The Effect of Allowing Body Weight to Fall on Recovering Bone too soon.*

An apparently sound bone may bend when the patient begins to walk, because steps are not taken to prevent faulty deflection of body weight. Textbooks are too optimistic about the period of time requisite for complete consolidation to take place. This has been shown in a series of fractured femora measured at subsequent dates after the patient had been allowed to walk. In each case a certain amount of telescoping had occurred. It is also a fact that one can frequently refracture a bone by manual manipulation after eight to twelve weeks.

For the prevention of deformity during the period of after-treatment it is necessary to take a large amount of weight-bearing strain from the fracture. It is a good working rule to fit all fractures of the femur with walking callipers for at least eight weeks after the bone is considered sound enough to let the patient up. Corresponding fractures of the upper third of the tibia should be similarly treated. Patients who have had fractures of the middle and lower thirds of both bones and Pott's fractures should be allowed to walk with a light outside iron extending from the heel of the boot to two inches below the knee-joint, and the inner side of the sole and heel of the boot should be built up a third of an inch in order to prevent the valgoid deformity that is otherwise so apt to manifest itself.

NON-UNION.

Some fractures are slower than others in beginning to unite, and here the surgeon must possess his soul in patience and leave the fracture alone. Too much interference in the way of constantly taking splints off and moving the fragments to see if union is occurring is apt to end in non-union.

Treatment by what Thomas called damming and hammering is of assistance. Passive congestion by means of rubber tubes tied above and below the fracture, sufficiently tightly to impede venous return, should be carried out for increasing periods of time every day until two to three hours is borne without undue discomfort. The ends are hammered by a small leather-covered wooden mallet twice a week to produce subperiosteal stimulation, and thus acts in the same way as the method of rubbing the ununited ends of the bone. Where non-union is definitely established, and where conservative means as outlined above have failed, the question of operation arises. In fractures of the lower extremity operation should be postponed until the effect of the patient getting about with the aid of an appliance has been tried without success. The number of stubborn non-unions that respond to this simple procedure is surprising. The need for operation having arisen, the question whether this should consist of freshening the fractured ends and bone-plating or bone-grafting is one which depends on personal choice. For myself I invariably use a bone graft; it is preferable to get the graft from the tibia rather than to use a slide inlay of the involved bone, as this is invariably posed as a result of prolonged disuse. Plating is obviously preferable to wiring for immobilizing the freshened ends where bone-grafting is not resorted to, but a circular wire loop is often of advantage where the non-union is merely due to the interposition of muscle or fascia.

If comminuted fractures appear to require operative interference, it is advisable to leave all splintered bone in position, even in the presence of sepsis. This was impressed on us all during the war. The wholesale removal of bone fragments is apt to result in non-union.

The Signs of Faulty and Delayed Union.

If there be pain over the site of a fracture of old standing, especially on digital pressure, unsound union may be suspected, and if this pain be accompanied by an exuberant callus formation the diagnosis is absolute. If malunion be present in addition, manual manipulation with the aid of a wedge will be sufficient to correct the deformity, and the irritation so caused may expedite firm union; congestion and hammering may also be used with advantage.

Operation or Splinting.

The question what fractures should be treated at once by operation, and which by splinting, must be answered by each individual surgeon according to his mechanical or operative aptitude.

I generally operate on spiral fractures of the lower third of the leg by means of inlay grafts, but plating is equally satisfactory in skilled hands. Fractures of the patella in the transverse axis I treat by wiring, as also fractures of the olecranon, where there is a large gap with rotation of the fragment. I also operate on scaphoid fractures where the proximal fragment prevents full hyperextension of the wrist and where there is palmar dislocation of the semilunar. Removal of the proximal portion of the scaphoid is generally sufficient.

All other fractures I endeavour to treat by means of splinting or posture, or both, combined in some cases with rigid extension and counter-extension.

FRACTURES OF THE LOWER EXTREMITY.

Fractures of the neck of the femur and of the upper fourth of the shaft are best treated in the double Thomas frame with extension straps on both legs, the affected limb being widely abducted. The groin strap round the groin on the sound side gives adequate counter-extension (Fig. 2).

The exception is in cases of old people, where prolonged recumbency is contraindicated on account of the risk of pulmonary congestion. One must judge by general appearances; the plethoric type of old age fares badly on a

frame. In these cases it is advisable to fit a walking calliper made half an inch too long and allow the patient up on crutches. The American school uses a plaster

spica in wide abduction—the so-called Whitman position—instead of the Thomas frame.

The question of separating fractures of the neck depends on the amount of deformity: unless there is extreme rotation outwards of the whole leg the condition is best left alone in old people.

Careful nursing is essential in cases treated on a frame; the back must be carefully rubbed with talcum powder twice daily, the flat of the hand being carefully interposed between the skin of the back and the pad of the frame. An alcohol rub twice weekly

is also necessary. With these rules strictly obeyed no skin trouble need be feared.

Fractures of the middle and lower portions of the shaft of the femur, fractures of condyles, and fractures of tibial tuberosities and shaft in the upper three-fourths, are all treated in the Thomas knee-bed splint. I have heard it said by men who are not conversant with this splint that pressure sores are common with it, and for that reason they carry on with the long Liston splint. With proper nursing precautions pressure sores under the ring of the splint should be unknown, despite the tremendous pressure to which the skin in the region of the tuber ischii is subjected when heavy traction is required. Here again the skin round and under the ring must be carefully rubbed with talcum several times a day; the patient usually does it himself under supervision; rubbings with alcohol are also required to harden the skin. The skin in the region is so movable, that a fresh area can be subjected to pressure by merely pulling or pushing it under the ring; the same effect can be produced by slightly altering the position of the limb into various degrees of flexion, abduction, and adduction. Where it is difficult during the first two or three days to reduce the shortening of the limb (the dangerous period for pressure necrosis of the skin under the ring), it is advisable to tilt the foot of the bed, and fasten the lower end of the splint to the lower bars of the bed. The body weight thus keeps up and tends to increase traction, and at the same time reduces pressure on the skin of the buttock.

I use adhesive straps made of coarse holland, which I find last longer than Sinclair's glue, and I do not bend the splint either at the knee or at the site of fracture in

FIG. 3.—Use of malleable iron posterior splint in fracture of the middle third of the femur.

femoral cases. To preserve the antero-posterior convexity of the femur and to prevent hyperextension of the knee I use big pads interposed between the leg and the malleable iron splint which is slung beneath. This fracture-splint should run from a point two inches below the gluteal fold to the lower third of the leg (Fig. 3).

In fractures of the lower third of the femur a big pad is required beneath the site of fracture; if despite firm traction the backward distortion of the lower fragment remains, it may be necessary to divide the tendo Achillis; this, however, is very seldom required. Angulation is prevented by the application of laterally applied bandages fixed to the side bar of the bed-splint.

The use of callipers, ice-tongs and Steinmann's pins to produce traction are complications which are only applicable in hospital and in the hands of experts, and in a large percentage of cases are unnecessary.

Fractures of the tibia, with the exception of Pott's fracture, are treated on the same lines, and fractures involving the knee-joint require adequate restoration of fragments by manual pressure combined with traction. The fragments are easily controlled by a broad ring of adhesive strapping around the leg.

The reduction of a Pott's fracture is of greater importance than the splinting. Forceful traction with the foot in extreme extension combined with a downward pull on the leg and an upward pull on the heel to reduce the backward displacement of the foot should reduce the deformity, but occasionally it is necessary to divide the tendo Achillis. The foot is then forcibly inverted into an over-corrected position. Side-splints of metal extending from the knee-joint, the outer one projecting three inches beyond the heel, are suitably padded to keep up the inversion and bandaged into position. The projecting portion of the outer splint is now bent inwards to meet the inferior extremity of the inner splint. A box is thus formed which, when duly bandaged, keeps the foot at a right angle and prevents the dropping back of the heel. In fractures of the tarsus, when reduction is complete, all that is necessary is for the foot to be kept at a right angle.

• FRACTURES OF THE UPPER EXTREMITY.

Fractures of the humerus in the region of the shoulder-joint, if inefficiently treated, may become malunited with, as a result, limitation of abduction and external rotation. Fractures in the region of the elbow-joint are apt to result in defects of flexion and supination. Supination is often deficient in fractures of both bones of the forearm, and the deformity of a malunited Colles's fracture, with limitation of wrist movement, of pronation and supination, and of finger flexion is well known.

Fractures of the anatomical neck of the humerus are best treated by a wrist sling which allows the weight of the arm to act as an extension—a pad in the axilla to produce slight abduction of the upper arm, and an encircling bandage round arm and trunk to fix the humerus.

Separation of the upper humeral epiphysis in childhood or adolescence may produce marked abduction and external rotation of the upper fragment, which, if unreduced, will result in inability to raise the arm above the head. In treating this condition it is advisable to abduct the arm to a right angle and to rotate it outwards till the hand is level with the mouth, and to immobilize the arm in this position either by one of the humerus abduction splints or in plaster (Fig. 4). Sometimes the amount of abduction and rotation are so extreme that it is necessary to fix the arm in plaster above the head in what may be termed the "Kamerad" position.

FIG. 4.—Humerus abduction splint.

Fractures of the surgical neck are often impacted, and the question of disimpaction depends on the abduction deformity of the upper extremity. Should it be found necessary, the method of Thomas (Fig. 5) is excellent. The patient is seated on a chair near the wall and a roller towel is passed under the axilla and fastened to a coat-hook or nail. A wrist sling is fastened round the neck and a clove hitch is made fast to the elbow with a long loop which comes to within a foot of the floor and which acts as a stirrup for the operator's foot. Extension is thus obtained, leaving both hands free for manipulation. The axis of the pull is brought to the abducted position, and when reduction appears complete the arm is forced upwards and reimpacted. Treatment is now carried on as for fractures

of the anatomical neck except that a larger axillary pad is indicated.

Fractures of the shaft are treated by malleable iron fracture splints, which can be bent to cover in the shoulder-joint and thus produce fixation.

All fractures in the region of the elbow-joint, with the exception of the olecranon, are treated, after adequate and

FIG. 5.—Thomas's method for reduction of impaction in fracture of the surgical neck of the humerus.

complete reduction, in the Jones or fully-flexed position. This position cannot be obtained unless reduction is complete. Whether the fracture is supracondylar, T-shaped, or intercondylar, one must reduce by traction-extension, supination, and hyperflexion, and, if the latter cannot be obtained, the routine must be repeated until it is, and the arm must then be kept in this position at rest for at least three to four weeks. A warning must be given against passive movements after the arm is being gradually brought down, otherwise traumatic arthritis and consequent stiffness of the elbow ensues. As an empiricism it is advisable to let the wrist sling down a little every week until the arm is at a right angle at the end of the sixth week. After the fourth week the patient can use the arm in the sling with moderation, and massage may be given as an adjunct to treatment, but forcible passive movement is absolutely contraindicated. For this type of fracture the rectangular internal splint should be abolished.

Fractures of the head and neck of the radius must be fixed in full supination, otherwise limitation of this movement will certainly result. Fractures of the shaft of both bones require consideration of two important points: first, the shaft of the ulna must be kept straight, and secondly, the curve of the radius must be conserved as the

FIG. 6.—Splints twisted for the treatment of Colles's fracture.

whole length of the posterior border of the ulna is straight, and on this the curved radius rotates like a bucket handle. There must be no lateral pressure on the middle of the radius, otherwise synostosis may ensue. In the position of supination the bones are farthest from each other, and so we should treat all our shaft fractures in this position. Nearly all neglected fractures of the forearm show limitation of supination, whereas pronation is not defective.

Colles's fracture requires complete and adequate reduction before splinting takes place. The Jones method is preferable to the hand-shaking plan, because

the force is applied directly to the bone instead of working through the carpal bones. Twisted fracture splints (Fig. 6), adequately padded to keep the replaced fragments in an over-corrected position and the hand in ulnar deviation, are applied and remain for four weeks, movements of fingers and thumb being allowed from the first.

Further Observations

ON

THE ETIOLOGY OF ECLAMPSIA AND THE PRE-ECLAMPTIC STATE.

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.,

ASSISTANT PHYSICIAN, ROYAL MATERNITY HOSPITAL; TUTOR IN GYNAECOLOGY, UNIVERSITY OF EDINBURGH;

AND

DOUGLAS A. MILLER, M.B., Ch.B.,

ASSISTANT TO THE PROFESSOR OF MIDWIFERY; RESEARCH SCHOLAR, UNIVERSITY OF EDINBURGH.

This paper contains confirmation of an explanation of eclampsia which one of us published in 1914. It is based on a study, carried out at the Royal Maternity Hospital, Edinburgh, of 40 cases of toxæmia and associated conditions. The original investigations professed to show that the eclamptic and the pre-eclamptic toxæmia is dependent on a placental necrosis and they culminated in the experimental reproduction in animals of a disease closely simulating the classical picture of eclampsia. The first observations were concerned with a study of the pathology and with experiment. We propose now to give a third link of proof—the clinical.

Eclampsia and the pre-eclamptic state of toxæmia are due to the circulation in the mother's blood of a specific substance or specific substances, that have, as their dominating effects, (1) degenerative changes in the kidney and albuminuria, (2) characteristic necrotic lesions in the liver, and (3) convulsions. The symptom-pathological complex is found only in pregnancy, and it is therefore dependent, in some way or other, on the child or placenta or both, and its occurrence in cases of hydatid mole, where there is no foetus, points to the placental elements as the source of the poison.

Placental disease of the nature of infarction is common in eclampsia and pre-eclampsia. In fact, the typical case of long-standing albuminuria of pregnancy shows multiple pale areas of necrosis in the placenta. On the other hand, many cases of fulminating eclampsia show no obvious change in the placenta, and the natural inference for long was that, where infarction is present, it is only of secondary importance. If related to the toxæmic state at all—and related it must be, everyone who has studied the subject admits—it is considered as more the result of the toxæmia than the cause.

What first directed our attention to the subject was the discovery that, although obvious placental disease might be absent in the placenta of fulminating eclampsia, which ends in rapid labour or death, in the other, less virulent type, in which some days or even weeks elapse between the seizure and the birth of the placenta, there is always massive necrosis visible to the naked eye. We have seen no exception to this. Its recognition threw a flood of new light on the subject. It showed that the degenerative change is always present in the placenta, but that it requires some days before it evolves into the form of ordinary naked-eye infarction. As a matter of fact, the recognition of the real character of the change has made it possible of detection at an earlier period if it is looked for.

If these observations are correct they have a double significance. In the first place, they provide us with a tangible focus for the origin of a placental poison. If we except Veit's discarded theory of the deportation of chorionic villi into the blood stream, they offer such a focus for the first time. In the second place, they

*Read before the Section of Obstetrics and Gynaecology of the Royal Society of Medicine.

indicate that, if the necrotic areas are the source of the eclamptic poison, this poison is produced during the early autolysis of the disintegration process, and whilst the structure of the placenta shows no, or only few, visible signs of change. By the time the process has progressed to the stage of ordinary naked-eye infarction the damage has been done.

Gradual piecemeal involvement of the placenta may produce in the end an extensive infarction consisting of small isolated necrotic areas of differing ages and with no symptoms except a toxæmia, which may never at any one time be of a virulent nature, and may, in fact, escape notice. A sudden single massive placental death may, on the other hand, kill before there is even a trace of visible infarction.

At the time of our original investigations in 1914 the idea that products eliminated from the disintegration of tissues at such an early stage could be toxic was a new one in pathology. There were no analogies for other branches of medicine to guide and encourage us. That the impressions formed on the basis of our anatomical studies were, however, well founded was borne out in a very complete degree by the results of our experimental work. We showed that autolysis of the human placenta increased its toxicity to the lower animals, and, moreover, we demonstrated that the early autolytic materials are more toxic than those present later; it seemed as if the early toxic matter was labile, and, if left, became broken up into less noxious elements, perhaps as the result of the continued action of the cell-enzymes. We claimed at that time to have reproduced in the lower animals, by the injection of the early autolytic products of the placenta, a disease exhibiting the classical features of human eclampsia. At that time, as we have said, the conceptions underlying our belief were new in pathology. Since then, however, it has been recognized that similar factors operate in other diseased conditions, and so exactly have these new developments followed the lines laid down in our original investigations that they provide, by analogy, strong proof of our thesis.

We would specially direct attention to the investigations on the origin of shock (Quénou, Delbet, etc.), and more especially to the experimental reproduction of toxæmia by the injection of the products of damaged muscle. Delbet has demonstrated by an extensive and convincing series of experiments that the fission products of muscle are toxic even in the very earliest stages of disintegration. The results have been confirmed by others. A very interesting discovery made during these experiments was that the animal might die immediately or within a short time from an apparent intoxication of the nervous system. On the other hand, it might live for hours or a day or more, and then die from damage to the liver or suprarenal capsules. As Delbet says: "Ces morts retardées sont dues à des altérations du foie et des capsules surrénales." The application of these findings to eclampsia will become apparent in the latter part of this paper.

Our original investigations were arrested by the war. Since they were begun again, during the past year, we have confirmed our anatomical and experimental results. But here we desire more particularly to adduce another and different line of proof based on clinical observations. Before doing so perhaps it will be well to recapitulate briefly our previous observations on the pathology and etiology of placental infarction. Fortunately they are capable of easy demonstration.

Pathology of Infarction.

The pathological changes in an infarcted area of placenta are:

1. *Congestion in the intervillous spaces.* This, as we shall see, is due to a blockage of the corresponding maternal vessels.

2. *Congestion of the vessels in the foetal villi.* This is early and characteristic. The expansion of the vessels causes a swelling of the villi, which become closely packed together to form a solid block resting against the decidua surface, and sharply differentiated from the surrounding spongy placental substance. This hepatization is not entirely due to the turgescence of the individual villi. It is due also, and probably largely, to the tension of the envolving placenta which presses in on an area

in which the circulation is arrested. The infarcted block is thus really an area of collapsed placental tissue.

3. *Necrosis.*—During the necrosis the villi undergo disintegration of their cellular elements until in the end they are represented by mere ghost-like outlines. During the process the infarct passes through a series of colour changes. In the beginning it is purple or red, then it becomes chocolate-coloured, then brown, and, with the disappearance of the haemoglobin, the colour eventually of an old infarct is yellow or white. The entire evolution of change requires a considerable number of days.

The naked-eye recognition of infarction is easy when it is fully established; the pale infarct is so distinctive that it forms a prominent feature of the cut section of the placenta. The red or purple infarct is more likely to escape notice as its colour may not differ greatly from the surrounding placenta. Except in the early stages, however, it is solid and is therefore sharply cut off from the surrounding soft and spongy placenta. In the intermediate stages an infarct may be red in one part and pale in another. In many of the early cases the infarction can only be recognized when the cut section is gently washed with running water. This rinses the intervillous blood out of the healthy parts of the placenta, which become pale, and thus bring into sharp relief the purple blocks of infarcted tissue, in which the blood is clotted and is therefore not removed by the washing.

Etiology of Infarction.

As we have shown in another communication, the underlying factor is an interference with the maternal blood supply. This may be due to simple mechanical factors—for example, separation of the placenta from the uterus by trauma or retroplacental bleeding. These are the circumstances that commonly accompany a case of accidental haemorrhage. Another common condition of a somewhat similar nature is placenta praevia, the bearing of which on the questions under discussion will be mentioned later.

In many instances there is no evidence of placental separation or of retroplacental bleeding, and the local impairment of the blood supply that ends in placental necrosis is due to thrombosis. We have noted this frequently, and we believe it to be an important cause of infarction.

Accidental Haemorrhage and Toxæmia.

Retroplacental haemorrhage is a common cause of placental degeneration, and it possesses a special interest for us on account of the frequency with which it is associated with toxæmia. The frequency of albuminuria in accidental haemorrhage is given by different authors in figures varying from 30 per cent. to 80 per cent. or over. Our own ratio is nineteen times in a series of twenty-one cases—that is, 90 per cent.

It is often urged that the toxæmia is the cause of the bleeding, and one can see how the discovery of the common association of the two conditions should have given rise to this belief. But we would direct notice to some considerations that bring the validity of the common interpretation under question.

I.

In the first place, accidental haemorrhage is relatively much rarer in primiparae than in multiparae, though toxæmia is specially prone to affect the former.

II.

In the second place, a study of the etiology of accidental haemorrhage shows that a severe strain or other mechanical factor may cause the condition in a woman who was apparently healthy up to that time. The importance of a purely mechanical factor is well brought out by the clinical study of our cases. In 4 out of a series of 21 cases the bleeding followed the performance of such severe exertion as the washing of clothes, or it succeeded an accident, such as falling downstairs. And in all these cases there was albuminuria. In two cases the albuminuria developed after bleeding; the importance of this will emerge later.

In most cases of accidental haemorrhage the bleeding occurs in the site of least resistance—namely, in the displaceable retroplacental area. In other cases, however, the bleeding is widespread, and, coincident with the retro-

placental extravasation, there may be a deep infiltration of the muscular wall of the uterus and of the broad ligaments, a condition which has been called "diffuse utero-placental apoplexy." In our series there are two cases of this remarkable condition. In the one the extravasation involved the whole uterus and the broad ligaments on both sides. In the other the bleeding was localized chiefly at the right cornu and the adjacent part of the tube and broad ligament. The appearances are exactly those that would be produced by a sudden blockage of the right ovarian vein. The intense and sudden congestion of the uterus which is produced in these cases resembles the change induced in a pedunculated ovarian or fibromyomatous tumour by an acute torsion of its pedicle.

What is the cause of the sudden blockage of the veins in the pelvis that alone can account for a backward pressure sufficient to tear open the vessels of the uterine wall? Is it a thrombosis or a kinking, or is it due to a sudden increase of the intra-abdominal pressure?

III.

A study of the placenta in cases of accidental haemorrhage provides a third series of considerations in support of the theory which we are advocating.

Accidental haemorrhage may be divided into two classes: (a) those in which the placenta shows little or no evidence of degeneration, and (b) those in which the placenta exhibits degeneration of the detached area or areas.

(a) Here sufficient time has not been allowed for the full development of infarction. This category includes cases in which the birth of the placenta follows quickly on the onset of the bleeding, and in it are numbered most cases of external bleeding. Toxaemia is inconspicuous, and if present is represented by a slight transient albuminuria.

(b) Here the placenta throughout the detached area shows the signs of early infarction. The placenta has been retained in the uterus for some time, and, whilst the one part of the organ has remained intact and healthy, the other part has become transformed into a mass of degeneration. The degree of hepatization present is dependent on the interval that has elapsed between the local bleeding and the birth of the placenta. This observation is one which we have made so often that we have removed it from the category of the occasional or the accidental. It is invariable.

We have seen one case in which nearly half of the placenta was in a state of early purple infarction. In other cases the bleeding has taken place over small areas—the so-called "retroplacental haematomata"—and the infarcted regions are correspondingly small. Between these two extremes there are all grades in the extent of the retroplacental bleeding, and therefore in the size of the subtending areas of infarction.

Toxaemia is a dominating feature in this class of case. The most severe toxæmias in our series of retroplacental haemorrhage belong to this class. It includes five cases of eclampsia.

IV.

Finally, that the toxæmia is secondary is shown by the fact that we have actually demonstrated that it develops subsequent to the haemorrhage. In two of our cases an examination of the urine within a few hours of the bleeding was negative, whereas at a later examination albuminuria was revealed. An albuminuria develops so rapidly after the separation of the placenta that it is usually present by the time the patient is admitted to hospital. In many cases, especially of external bleeding, the albumin may never be present except as a trace. It develops early, and in the great majority of instances it passes off early.

It will have become apparent that, if our observations are correct, in order that a toxæmia may develop it is necessary that the placenta must maintain its attachment to one part of the uterine wall. Only otherwise can it receive and pass into the maternal blood the products of the adjacent necrosis. The placenta is like a large bag in which there is a free circulation of blood, and a necrotic area is thus like a poison-laden mass introduced directly into the maternal vessels.

A recognition of this fact accounts for the well known clinical observation that the toxæmia often ceases with the intrauterine death of the child and the complete separation of the placenta.

A suggestive analogy to the conditions which obtain in placental degeneration is supplied by the observations of Quénu in regard to shock. He showed that the application of a tourniquet to a shattered limb prevented the occurrence of shock by blocking off the source of the disintegration products, whereas the removal of the tourniquet by re-establishing a communication with the systemic circulation was followed by toxæmic symptoms. These observations are comparable to ours—toxaemia from the placenta can only arise and be maintained if and so long as part of the placental circulation persists.

Placenta Praevia and Toxaemia.

It sometimes happens that, in placenta praevia, the detachment of the placenta commences some time before the delivery of the uterine contents. If our thesis be correct such cases should be associated with a toxæmia. We therefore decided to conduct an investigation along these lines.

Albuminuria is the earliest definite sign of a toxæmia that we possess, and in this investigation, as in the similar investigation of cases of accidental haemorrhage, the presence of albumin in the urine was taken as the test. This sign is sufficient, but it is well known that a trace of albumin may be present without any other evidence whatever of a toxic process.

Toxaemia has, so far as we know, never been recognized as bearing any relation to placenta praevia, though a number of cases have been recorded in which low implantation of the placenta was combined with albuminuria. The concurrence has been, however, considered as a chance phenomenon. Recently Jardine and Kennedy reported a series of eleven cases of toxæmia so great as to lead to complete suppression of urine, and in two of these (that is, one in five and a half) there was placenta praevia. These conditions are each so rare that unless there is a possible mutual dependence they should occur together only once in several hundred thousand cases.

For this investigation, as for the similar investigation of the cases of accidental haemorrhage, a catheter specimen of urine was obtained as soon as possible after the admission of the patient to hospital, and also at subsequent intervals thereafter. In all the cases bleeding had commenced before their admission.

Our series consists of 7 cases of placenta praevia. Of these 2 had no albuminuria throughout. In 5 cases albuminuria was found. In 2 it increased from a trace at one examination to a heavy deposit at subsequent examinations. In 1 the albuminuria was absent at the first examinations and only developed later. In 3 of the patients the albuminuria was associated with other evidences of toxæmia, oedema of the face, headache, etc., whilst in one of these cases the toxic symptoms were so great that her condition caused considerable anxiety.

This record is striking, and it is, we believe, a powerful confirmation of the argument we are attempting to prove. The series is, however, too small to warrant any far-reaching conclusions, and we wish to avoid any such temptation. We would rather say that we welcome the opportunity of presenting this evidence, especially because it is of a nature that can be put to a ready test in any obstetric clinic. We shall be glad to hear the results of any others who make similar investigations.

The facts, however, raise a suspicion that in the past the toxæmia which apparently is liable to occur in placenta praevia has been overlooked and has been attributed to the collapse and the anaemia of haemorrhage. We may say that, as a control, we examined two cases of severe post-partum haemorrhage at intervals and in each case the urine gave negative findings. The changes in the detached praevia portion of the placenta are exactly those which we have described in the detached placenta of accidental haemorrhage. Where time has been allowed for their development the macroscopic and microscopic features of early infarction are found.

Other Causes of Placental Degeneration and Toxaemia.

In the preceding pages it has been shown that mechanical factors may cause a detachment of the placenta from the uterine wall, and, as in placenta praevia and in some cases of accidental haemorrhage, such a mechanical detachment is the cause of the degeneration that ends in toxæmia.

It often happens, however, that in cases of ordinary infarction of the placenta the exact cause of the impairment of the maternal blood supply is difficult or impossible to discover by an anatomical examination. In some such instances there is a thrombosis in the decidual vessels, and we believe that this factor probably operates in a number of cases. But it is impossible of proof, for one cannot tell from the microscopic appearances whether the thrombosis has preceded or followed the necrosis.

So, in many cases of eclampsia and albuminuria in which definite placental disease is present, the exact origin of the blockage of the maternal vessels may not be evident. We have shown, we believe conclusively, that such a blockage can alone account for the placental changes. How, then, are we to explain it in the absence of such simple factors as are present always in placenta praevia and often in accidental haemorrhage? Do mechanical influences operate in these cases as well?

In this connexion we would again direct attention to one of our cases in which the retroplacental bleeding was associated with a haemorrhage into the uterine wall, the tube, and the broad ligament in a way which we could only explain by involving a sudden strangulation of the right ovarian vein. In the other case of "diffuse utero-placental apoplexy" the appearances again suggested a mechanical strangulation of the veins, but here of both ovarian and perhaps of the uterine veins as well. The conditions were similar but more extensive.

We have referred to the remarkable and suggestive similarity between uteri showing these evidences of strangulation and an ovarian tumour or a pedunculated fibromyomatous tumour with a twisted pedicle. The conditions are so alike that it is almost impossible to escape the conviction that similar causes are operating.

If there are intra-abdominal influences, perhaps of the form of heightened tension, which can in their extreme form culminate in such a dramatic vascular change, it is almost certain that these same pressure factors act at other times in a less marked degree. It is known that, especially in primiparae, there are evidences of increased intra-abdominal tension—for example, swelling of the feet and legs and distension of the right ureter. Is it possible that similar agencies tend to cause venous stasis? In their extreme form this would result in complete strangulation, whilst in its more mild degree it would result in thrombosis of the veins of the retro-placental area or of the uterine wall.

Localized degeneration in the placenta must be due to blockage of the corresponding vessels. Of this we can be certain, but the ultimate explanation must remain of a theoretical nature until we have a more intimate knowledge of the vascular conditions that obtain in the abdomen and pelvis during pregnancy. Paramore maintains that he has actually demonstrated the existence of a heightened intra-abdominal pressure during pregnancy. We have not had an opportunity of carrying out investigations along these lines, but we have a strong belief that it is by such a research that we shall eventually explain the local necrosis of the placenta which underlies some, if not all, of the toxæmias of the end period of pregnancy.

Sequence of Pathological Changes in Eclampsia: Post-partum Eclampsia.

In eclampsia there are widespread evidences of a toxic process throughout the body of the mother, the most prominent of which are the damage to the kidney and liver and nervous system, and the oedema of the subcutaneous tissues. Whether these diffuse changes occur simultaneously in gradually increasing intensity, or whether they follow a definite sequence in their development, we have so far no means of knowing.

In the majority of cases, where the complex of changes culminates in an eclamptic seizure, the clinical picture is completed before or during labour. In other instances, however, the end stages are only enacted after birth, and the convulsions, coma, etc., develop some hours after the escape of the uterine contents.

Post-partum eclampsia constitutes a difficulty that must be candidly faced by the research worker, and it has long been apparent to us that an understanding of this variant of the disease would probably throw new light on the ultimate nature and origins of the toxæmia. Anomalies

are often of greater value than the commonplace features in directing attention to the underlying facts of a disease.

In a preceding communication we tentatively suggested that a piece of dying placenta retained in the uterus might account for the puerperal seizures. This idea we no longer hold, and we are not in a position to offer any other explanation that we can support with proof. We would direct attention, however, to some interesting analogies which may throw some light on the cause of delay in the manifestation of the symptoms in a *post-partum* seizure.

There are not a few toxæmias in which a definite interval is known to exist between the introduction of the poison and the development of the symptoms. In chloroform poisoning the phenomena of toxæmia may not develop for a day or two. But a more interesting analogy is phosphorus poisoning. Here the introduction of a toxic dose may lead to immediate signs of irritation. These pass off, and not till forty-eight hours later do the major evidences of toxæmia develop amongst which convulsions may be present. The analogy between the effects of these chemical poisons and eclampsia is brought home in a striking manner by a study of the tissue changes. In both of the chemical poisons massive damage to the liver occurs, and, in delayed chloroform poisoning, the liver changes may closely simulate those present in eclampsia.

It is impossible to avoid the inference that the immediate cause of the symptoms in such cases is the flooding of the system with the breaking-down products of the liver cells (and perhaps of other organs as well), which were killed at the time of the introduction of the poison, and which in their turn, after a varying but considerable period, generate a new and different poison.

We hold that a conception of this sort is reasonable, and it suggests that eclampsia, as we know it, is possibly not the manifestation of the immediate results of the placental poison, but it is dependent on the flooding of the mother's system with the fission products of the cells of the liver (and perhaps of other organs). It is, as it were, a secondary toxæmia that requires some hours or even days for its culmination. If this explanation be correct, it accounts for the occasional delay of the end stages of the toxæmia till the *post-partum* period.

The analogy of the toxic effects of damaged muscle, which we have referred to on a preceding page, is even more suggestive than that drawn from a study of the chemical poisons. The actual products eliminated from the dying tissues of the leg probably resemble those produced in the placenta. As the researches of Delbet and others show, the lethal result in the former case may be delayed for some time, and the animal eventually succumbs to the effects of the disintegration of the liver and suprarenal glands.

Treatment of Eclampsia and Albuminuria.

There are some suggestions with regard to the treatment of the toxæmias of pregnancy which emerge from this research.

1. Separation of the placenta and retroplacental thrombosis are in some cases, and perhaps in the majority of cases, the factors underlying placental degeneration. Mechanical influences, strain, undue exertion, etc., undoubtedly predispose to these occurrences. Rest should therefore form a cardinal part of the treatment of all such cases. In this way an albuminuria may subside because increasing degeneration of the placenta is avoided.

2. Immediate emptying of the uterus is, theoretically, the ideal line of treatment in severe albuminuria and in eclampsia. It is the ideal method, no matter what theory we adopt regarding their origin, for all are agreed that pregnancy is the ultimate cause. In view of the above theoretical considerations, however, it is possible that when major symptoms develop they owe their origin to a poison introduced into the system some considerable time before, and in the interval the placental danger has subsided or disappeared.

Considerations of this kind would account for the very varied results that follow evacuation of the uterus, and they make logical the attitude adopted by most obstetricians, that severe manipulative measures are apt to stir up the toxæmia to dangerous limits, especially by provoking convulsions, which are readily inaugurated by stimulation of the nervous system.

SUMMARY.

1. Eclampsia and pro-eclamptic toxæmia are due to the products of the early degeneration of a piece of placenta whose blood supply has been interfered with.

2. Infarction of the placenta may be due to mechanical detachment of the organ from the uterine wall—for example, in placenta prævia and in some cases of accidental hæmorrhage. In other cases it is due to thrombosis; this is the factor operating in most cases of eclampsia.

3. Where time is allowed for the elaboration of toxic elements from the detached placenta toxæmia develops. In concealed accidental hæmorrhage, therefore, toxæmia is conspicuous. Absorption of placental poisons only occurs if and whilst part of the placenta remains attached to the uterine wall.

4. Toxæmia occasionally accompanies placenta prævia for the same reasons.

5. The toxæmia develops after the hæmorrhage; it is therefore not the cause of the bleeding in accidental hæmorrhage.

6. The major symptoms of eclampsia are probably due to the flooding of the mother's system with the breaking-down products of liver cells (and perhaps of other tissues), which were killed some hours or days previously by the placental poison. Compare the interval that elapses before the development of symptoms in phosphorus poisoning, etc. A consideration of this sort accounts for the occasional occurrence of post-partum seizures.

7. Recent investigations on shock (Quénu, Delbat, etc.) support by analogy this conception of eclampsia. These observers have shown that the early disintegration products of muscle are toxic. The injection of these substances into an animal may kill at once. On the other hand, the lethal effect may be delayed for some time, in which case it is due to degeneration of the liver and suprarenal glands. The changes induced in the liver in such a toxæmia resemble those found in the liver in eclampsia.

This investigation was carried out at the instance of the Medical Research Council. It was conducted at the Royal College of Physicians' Laboratory, Edinburgh.

CARDIAC PERISTALSIS AND MITRAL STENOSIS.

BY

D. W. SANWAYS, M.A., M.D., D.Sc., M.R.C.P.,
MONTON, FRANCE.

In an article entitled "Dilatation of the Heart," published in the BRITISH MEDICAL JOURNAL of February 5th, 1921, I showed that the pressure which the cardiac walls can, theoretically, exert on their contents varies inversely as the cube of the diameter of the enclosed chamber. Thus, when a chamber has by contracting reduced its diameter by one-half, its walls could, because of their physical advantages, exert eight times as great a pressure on the enclosed residual contents, and when the diameter has fallen to one-third they could exert twenty-seven times the pressure that was possible at first, the force of contraction being the same throughout.

Not that I imagine that the cardiac walls can fully effect this, as they are not perfect spheres, and they have deficient muscular areas at their valve orifices. They must, however, be physically capable of more or less following the physical laws which govern contracting hollow spheres, and of exerting enormously greater pressures on their residual than their full contents, or, expressed otherwise, of expelling their residual contents with much less effort than their first expelled contents.

The principle to which I am calling attention can be readily appreciated by the purchase of a big rubber air-balloon with thick walls, as sold to children, and of a similar small rubber balloon with thin walls. If these are mounted on a three-way glass tube and air blown in by the free orifice, only the big balloon will dilate; the small thin balloon will resist the air pressure which dilates the large thick one. If, now, the inflated big balloon be clamped off and the small one separately inflated, and both afterwards connected together, the

small thin balloon will blow its contents into the large thick-walled one and inflate it further.

I maintain that there are conditions in the working of the heart in which the thin-walled auricle can similarly force its contents into the thick-walled ventricle when the ventricle is contracting against it, and that the appreciation of this fact is essential to understanding much that is observable in cardiology.

It is universally admitted that the auricle begins its contraction before the ventricle. The auricle, therefore, is becoming a small chamber while the ventricle is becoming a large one, through receiving the auricular contents. Towards the end of its contraction the auricle has but a few units of area of blood to contract on, while the ventricle, being full at that time, has many. The auricle also by contraction has thickened, while the full ventricle is at its thinnest. Should the contractions overlap, and the ventricle begin its contraction before the auricle has finished, the supposition of so many writers that the ventricle must in that case overcome the auricle is not evident. In the Bramah press it is not the big piston which overcomes the little one, but the reverse; and the full ventricle is at a greater relative disadvantage than the big Bramah piston, having a minimum of contracting efficiency at the moment when the area of resistance is at its maximum.

Now it is commonly supposed that the contraction of the auricle is over before that of the ventricle begins. This view does not accord with that of many of the most noted earlier observers who specially investigated the subject. Thus Dr. Barclay wrote: "The fibres forming the auricle being intimately associated with those which surround the ventricle, the two cavities do not contract and dilate alternately, but the contraction of the one overlaps to some extent that of the other." He added, however: "When the mitral valve is much altered, the more powerful contraction of the ventricle must overcome that of the auricle if there exists anything like an opposition between them."

Professor Potain, the greatest French authority during the last half-century, maintained that, normally, the closure of the auricular-ventricular valves corresponded in time with the opening of the aortic valves, and that the contraction of the auricle lasted till that closure. Had he been able to conceive that the auricle could oppose the ventricle, if their contractions overlapped, he would not have been forced to place, as he was, the beginning of the ventricular contraction at the moment, or just before, the aortic valves opened.

Professor Potain heard the murmur of mitral stenosis (so-called "pre-systolic") during the apex beat, and, believing it to be due to the auricle, maintained that the ventricular contraction must begin later. Dr. Dickinson heard it also during the apex beat, and maintained that it must therefore be ventricular-systolic in origin. The trouble with these observers was that they could not imagine that the auricle could drive its blood on in spite of the ventricle if their contractions overlapped, whereas I have shown that the chance of the auricle being physically able to do this is greater than the chance of the ventricle being physically able to oppose it, especially when the auricle is hypertrophied.

In the classic investigations made by Professors Roy and Adami² graphic tracings are given showing the relation in time of the chief cardiac events. Roy and Adami actually placed tambours in the cardiac chambers so that the various pressure changes could be exactly recorded. The auricular contraction, as given by them, was at its maximum when the apex beat was at its maximum, and had not finished, in normal cases, when the aortic valves opened, thus showing a marked overlapping of the auricular and ventricular contractions.

Moreover, in harmony with this, Roy and Adami found that the papillary muscles did not contract to support the auricular-ventricular valves till the moment when the aortic valves opened. This strongly suggests that some other force was supporting these valves during the first part of the ventricular contraction. That force, fairly obviously, must have been the contracting auricle itself, which I maintain was physically competent to do it. An overlapping of the systoles is probable a priori, for primitive cardiac contraction is peristaltic, and the essence of a peristaltic contraction is that each segment in sequence takes up the contraction and maintains it during the

expulsive period of its successor. In this way the great veins near the auricle contract and close first, and maintain their contraction during the expulsive period of the systole of the auricle. It would require an infinite force to open a fully-contracted vein, so that regurgitation from the auricle is amply prevented. A sphincter is as good as a valve to protect the veins. In birds the mitral valve itself is only a sphincter.

When the auricle contracts, it likewise appears to maintain its contraction, prolonging it into ventricular-systolic time, thus for a period supporting the auricular-ventricular valves. The ventricle also appears to maintain its contraction, as Roy and Adams's curves show, for an appreciable period after the outflow of blood into the aorta, thus for a time supporting the aortic valves.

In the case of mitral stenosis any overlapping of the contraction of the auricle on to that of the ventricle is obviously likely to be increased. It is difficult for the auricle, even if hypertrophied, fully to expel its contents through the stenosed mitral orifice before the advent of the ventricular contraction; and just as the contraction of a ventricle is normally longer than that of an auricle, because of the greater opposition its contraction experiences, so the resistance opposed to the auricle, when the mitral orifice is stenosed, is likely to prolong its contraction, and make it more ventricular in character.

Keyt of Cincinnati, as quoted by Professor Marey, maintained that "one of the characteristics of aortic stenosis was the long duration of the ventricular systole." Dr. Hilton Fagge wrote: "If the mitral orifice be stenosed, the contraction of the auricle will be slower than normal, and the beat of the ventricle will thus be delayed." Dr. Galabin and Dr. Mahomed made very similar statements, after examining their graphic curves taken in cases of mitral stenosis. Dr. Sansom¹ wrote: "It is obvious not only that the auricle (in mitral stenosis) contracts in a manner much more powerful and much more prolonged than under normal conditions, but also that it contributes in very marked degree to the general elevation (apex beat) which is completed by the systole of the ventricle." French writers, such as Dr. Constantin Paul, have advanced much the same opinions.

Observers such as these could not follow to a useful conclusion the evidence of their senses, because they believed that the power of the auricle did not count as compared with that of the ventricle, and that any overlapping of their contractions could have no physical utility.

As a matter of fact there is no obvious reason why, if the auricle has contracted to, say, half its diameter, in a case of mitral stenosis, before the contraction of the ventricle opposes it, the auricle should not continue to send on its residual contents into the full ventricle, the aortic valves opening, or the ventricle expanding to receive them. This is rendered the more possible by the fact that the walls of the ventricle, in well marked mitral stenosis, are thinner than normal, while those of the auricle are hypertrophied. I have seen an auricle with walls hypertrophied almost to the thickness of the ventricle. Dr. B. Foster and Dr. Sansom have reported auricles with walls measuring up to 6 mm. in thickness, exceeding, that is, the thickness of the right ventricle.

The ventricle can never exert its potential power of opposing the inflow of the residual blood from the auricle, because directly its contraction has raised the intra-ventricular blood pressure above that in the aorta its contents escape into the latter, and no further raising of blood pressure on its part is possible. The maximum resistance the auricle could, therefore, ever find opposed to it by the ventricle is determined by the pressure in the aorta, and an auricle towards the end of its contraction, especially if hypertrophied, could, theoretically, being small, exert a sufficient pressure on its residual contents to overcome this. Allen Durns described a case under his observation in which the ventricles became calcified, and the man lived for a long period with the auricles alone doing the whole work of the circulation.

It may be objected that in cases of mitral stenosis the auricle dilates as well as hypertrophies. I believe this to be one of the fictions of medicine. In a paper published in 1893² I gave particulars of an analysis I made of all the post-mortem reports of Guy's Hospital during the ten years 1886-95. Out of a total of 4,791 necropsies during that period, there occurred 196 cases of stenosis of the mitral orifice. Of these cases, 23 came from the surgical wards,

and only one among them appeared to have died of a systole due to the stenosis, which was severe. If this case be excluded dilatation of the left auricle was only observed in 3 of the remaining 22 cases, where death occurred from accident or operation before the heart broke down. Dilatation, therefore, is not a feature of the disease during its course. I doubt if 3 in 22 be materially greater than the average for the heart generally at necropsies. The paper referred to established the fact, so far as statistics could establish it, that the characteristic change in the left auricle in mitral stenosis is hypertrophy, and that dilatation is a break-down phenomenon occurring late in the disease.

CONCLUSIONS.

1. There is considerable evidence to show that the contraction of the auricle normally overlaps that of the ventricle, lasting probably till the moment of opening of the aortic valves.
2. That in cases of mitral stenosis this overlapping tends to be still further prolonged, invading therefore the expulsive portion of the ventricular systole.
3. That the ventricle could not prevent the auricle sending its residual blood into it, if their contractions overlapped, because at that time the auricle, being small, would have few units of area of blood to contract on, and a thickened mass of muscle to exert the necessary pressure, whereas the ventricle would be in exactly the reverse position at the time.
4. In cases where the mitral was stenosed the auricle would be farther helped by hypertrophy of its walls and thinning of those of the ventricle.
5. That the murmur of mitral stenosis ("presystolic") goes up to and into ventricular-systolic time because the blood flow does likewise.
6. That the murmur is "crescendo" in character because the auricle can exert an ever-increasing pressure on its contents as it contracts. Theoretically the pressure can increase inversely as the cube of the decrease in diameter.
7. That regurgitation through an incompetent mitral orifice is prevented, probably for years, by the contraction of the auricle behind that orifice during the expulsive portion of the ventricular systole.
8. That the presystolic murmur is replaced by a systolic murmur when the auricle cannot decrease its size in time to become a sufficiently small chamber to defeat the oncome of the intraventricular resistance, but on the contrary is defeated by it. This will allow regurgitation, the auricle will speedily dilate, fibrillate, and compensation will break down.
9. Temporary recovery by rest or bleeding will probably mean that the auricle becomes again, for a short time, master of the situation.

BILHARZIA DISEASE IN EGYPT.

BY

J. B. CHRISTOPHERSON, C.B.E., M.D.,
F.R.C.P., F.R.C.S.

TROPICAL DISEASES CLINIC, MINISTRY OF PENSIONS; LATE DIRECTOR
OF THE CIVIL HOSPITALS OF KHARTOUM AND OMBEHA.

THE outstanding facts in Drs. Lasbrey and Coleman's article on 1,030 cases of bilharzia treated by antimony tartrate, in the issue of the *BRITISH MEDICAL JOURNAL* of February 26th, are, as it seems to me—

1. The prevalence of the disease in and around Cairo.
2. The applicability of the treatment of bilharzia—both complicated and uncomplicated cases—by intravenous injections of antimony on a large scale in Egypt; and, most striking of all,
3. That the prestige of the British doctors with the fellahen of Egypt, at the present period of national unrest, is proof against the prejudice aroused by religious and political mischief makers.

The cases were all voluntary, and, since the completion of this series of 1,000 cases in August, 1920, another 1,000 have been done in five months. The C.M.S. Hospital, Old

Cairo, is by no means the only hospital in Cairo where large numbers of bilharzia cases are coming for treatment; the Kasr-el-Aini Hospital, if my information is correct, has treated about 1,600 cases of bilharzia by the intravenous method during twelve months, and other hospitals and practitioners in Cairo are similarly treating numbers of patients, though naturally on a smaller scale; also the Government hospitals in the provinces, some of which have a still larger number of cases to their credit even than the Kasr-el-Aini, and other hospitals, are carrying out the treatment. The great number treated is striking, but bilharziasis is so deeply rooted and prevalent in Egypt that, in my judgement, hospital treatment alone, even on this large scale, will take a long time to make an impression on it as a national disease; the sources of reinfection, too, are many. It should be remembered, however, that each case, when cured by antimony tartrate, ceases to convey infection, owing to the fact that the ova deposited in the bladder and rectum are also killed by the remedy—in other words, the patient ceases to be a "carrier."

The report of the first 1,000 cases treated at the C.M.S. Hospital, and the lucid description of the simple technique employed, is testimony that antimony tartrate is efficient for dealing with bilharziasis on a large scale, and capable of being applied in Egypt. Antimony tartrate is cheap, the cost of the amount sufficient for the course of treatment for one case is 1s. It is stable, it is easily procurable, it is soluble, and solutions containing it can be sterilized by boiling as often as necessary before use. These facts are all advantageous for working in a sub-tropical country and in out-stations. Antimony tartrate, when given by the veins, is, in all probability, not so toxic to the patient or injurious to the tissues as is generally supposed.

The method of administration is simple of application, but, as Drs. Lasbrey and Coleman's article shows, it needs practice, and, if carried out on a large scale, the arrangements need considerable organization. There are many details of method to attend to. Finally, it is not a remedy to be placed in the hands of the careless and the inexperienced.

Bilharziasis is so prevalent in Egypt, and the sources of reinfection after treatment are so numerous, that this direct method is alone not sufficient for dealing with the disease nationally, and in this connexion there is a trait in the character of the Egyptian which militates against the success of simple hospital treatment. The course of treatment at present lasts at shortest seventeen days, and usually three weeks; it may take a month. The Egyptian fellahceen reserves to himself the right to determine when the cure is completed. When he is free from pain, when his urine looks normal, when the act of micturition is normal, then, according to his standard, he is cured. His decision is made often too early, as the doctor knows from microscopic investigation. However, the patient thinks he is cured, and he goes away and cannot be traced. This happens possibly in one-third of the cases treated in Egypt, and it was found advisable by Drs. Lasbrey and Coleman to let the patients bring their mats and sleeping paraphernalia and to accommodate them in the hospital grounds during the course. The only drawback I know to out-patient treatment is this liability of patients to cease attending before the course is completed; it is a serious one, however, and as patients with bilharzia are very numerous in Egypt, and as it is impossible to treat a whole nation in the wards of a hospital, treatment modified according to circumstances is necessary and advisable. Treat the patients as out-patients, but take the treatment to the villages of the people, would seem to be the solution.

Many of the cases—they are the worst from the point of view of spreading infection—are too mild for the sufferer to bother to see a doctor; others are too bad, and, believing there is no cure, die in their villages. Practically the majority of sufferers will not seek hospital relief of their own accord. Therefore the organization of small mobile out-patient hospitals is needed with mobile laboratory attached, and a staff chiefly or in some instances entirely composed of Egyptians; it would take up a position in or near a village and would, from the Omdar or Sheikh, get a list of sufferers; such a mobile hospital would particularly work through the schools—the young are the chief sufferers.

I am not so optimistic as to believe that a clean sweep of the bilharzia cases in any village would be made in the

first instance, or for some years, but if care were taken to send only experienced and careful workers (Egyptian to preference) whose judgement as regards the dose and whose skill in the technique of the operation, and whose care in the preparation of the paraphernalia can be relied on, confidence would be secured and sufferers would come forward voluntarily, and, after a short time, there would be less trouble in applying the injections than there is in doing vaccinations for small-pox. In a short time a travelling hospital, instead of sitting down near a village and treating only a percentage of the sufferers, would be welcomed and would remain until all the bilharzia cases in the vicinity suitable for treatment were dealt with. It would then move on to fresh ground. Cases which were unsuitable for out-patient treatment would be sent to a hospital—no doubt in the car attached to the mobile unit.

But the organization of mobile hospitals, together with the present general hospital treatment, extensive though it is, is in itself not sufficient to deal with so prevalent a disease as bilharzia in Egypt on a national basis.

Leiper's discovery of the life-history of the bilharzia schistosome—its extra-corporeal stages of development in the mollusc (*Bullinus* and *Planorbis* in Egypt)—placed Egypt in possession of information the practical value of which lies in the fact that it can be applied on an economic basis for the purpose of extermination of the mollusc, and so stamping out bilharzia. Without these molluscs bilharzia disease could not exist in Egypt. It is probably impossible to eliminate the molluscs completely, but an advance can be made in two directions in dealing with them. In the first place an attempt may be made to exterminate them, and, in the second, measures may be taken to try and prevent those which cannot be exterminated from becoming infected with bilharzia.

But bilharzia will not be eliminated as a national disease from Egypt by the application of the antimony tartrate remedy, although supplemented by the hygienic measures suggested by Leiper¹ for dealing with the all-important mollusc—sound and thorough though they undoubtedly are. In order to achieve the object in view the co-operation of the natives must also be sought. That they will co-operate in spite of religious prejudices, ignorance and primitive notions, is evidenced by the fact that so many as 1,000 cases of bilharzia in one year at one voluntary hospital and 1,000 at another voluntary hospital in the same town sought the treatment.

The Egyptian mind is receptive; education by lessons at the primary school, by instruction at hospitals, by instruction of the general public by propaganda work, lectures, magic lanterns, advertisement posters, cinematographs—in fact education by publicity is what it needs.

It must not be thought that nothing is now being done by the medical authorities in Egypt. The Egyptian Sanitary Department is fully alive to the importance of this great question of bilharziasis. It has arranged for treatment to be carried out in the Government hospitals, and is moving in the direction of education of the fellahceen by means of lantern slides and diagrams and lectures. Native unrest possibly has prevented more being done so far.

CONCLUSION.

In order to eliminate the scourge from Egypt, it might be dealt with systematically on a much larger scale, and steps might now be taken to get rid of it by supplementing the present stationary hospital arrangements—

- (1) By working through the country with mobile hospitals with laboratory attached;
- (2) By adopting measures for the destruction of molluscs, and for preventing those which cannot be destroyed becoming infected;
- (3) By education of the fellahceen in the causes, prevention, and cure of the disease, and acquainting them with the life-history of the parasite by means of lantern slides, pictures, posters, lectures, cinematographs. The mobile hospitals would with advantage have a cinematograph attached, and the three great helminthic diseases of Egypt—*Hymenolepis nana*, ankylostomiasis, and bilharziasis—"featured." There is no reason why the cinematograph should not be used in this important medical educational work, with very great advantage to Egypt.

FIVE HUNDRED CASES OF MALARIA IN PENSIONERS.

BY
JENNER HOSKIN, M.R.C.P.,

HONORARY PHYSICIAN, QUEEN MARY'S HOSPITAL FOR THE EAST END.

DURING the latter half of 1919 a very great number of demobilized and discharged soldiers appeared before the various pensions' boards throughout the United Kingdom, claiming for disabilities incurred during service in the late war.

The following table gives the correct figures for the months of October, November and December, 1919:

	Oct. 1919.	Nov. 1919.	Dec. 1919.	Total for 3 months.	Per- centage.
Total malarial cases	5,626	6,702	6,972	19,300	7.7
Total number of cases	77,308	85,461	84,518	247,287	100
Total wounds and injuries cases	2,454	23,826	29,418	55,698	33.8
Total diseases cases	52,441	55,635	55,100	163,176	66.2

These numbers comprise all those men who have appeared before the pensions' boards during these three months. Of the total, 33.8 per cent. were claiming a pension for wounds and injuries, and the remaining 66.2 per cent. for various diseases. The malarial cases examined during this period were 19,300, or 7.7 per cent. of the total number of cases seen—that is, 1 in every 13 cases. Comparing the malarial cases with other diseases, the percentage is 11.6, or 1 in every 9 cases. Since obtaining these figures the proportion of malarial cases seen has increased.

From the United Kingdom 5,704,416 men were sent overseas, and of these roughly 400,000, or one-fourteenth, served in malarial countries.

Thus it can be realized that malaria has played a big part, not only amongst the casualty diseases during the late war, but is still continuing to cause a large amount of sickness and expense, both through loss of man power and pensioning at the present time. This shows that the incidence of malaria in those serving in countries where the disease is endemic is very high, and that the prognosis as regards complete recovery is bad.

The 500 cases to be described were examined consecutively at the Ministry of Pensions, and comprise 356 men who contracted malaria on the Salonica front, 62 from Egypt and Palestine, 45 from East Africa and 37 from other theatres of war, including a few recurrences of fever contracted during service in India prior to 1914.

I have endeavoured in these cases to compare the three main malarial theatres of war—that is, Salonica, Egypt and Palestine, and East Africa—and to show in what respects their immediate and later effects resemble and differ from each other.

1. *Discharged Medically Unfit.*—The following table gives the totals and the percentages:

	Total.	Percentage.
Salonica	45	12.6
East Africa	13	28.9
Egypt and Palestine	5	8.1
Miscellaneous	6	15.2
Total for all theatres	69	16.4

Thus over 16 per cent. of these collected cases had been discharged permanently unfit. This is a considerable proportion since it does not take into account the large number who have died from the disease. The other feature about the above table is the high percentage, 28.9, of the cases contracted in East Africa.

2. *Length of Service.*—There was also quite a marked difference in the average time spent in the malarial country before the soldier was transferred to a non-malarial theatre of war. The following table shows that the average time spent in East Africa was considerably less than that spent in Salonica and in Egypt and Palestine.

It is difficult to account for the difference, but it seems that the length of the lines of communication had a great deal to do with it. This was in connection with the difficulties in bringing up hospitals with adequate accommodation and necessary comforts, and in setting up ordnance depôts where the men could be provided with fresh boots and clothing to replace those worn out or lost on the campaign.

Theatre of War.	Average Time in Months.
Salonica	21.23
East Africa	14.15
Egypt and Palestine	24.37

In all these three theatres of war, malignant tertian fever was common. Unfortunately, I was only able to get a record of the type of infection in a very limited number of cases. All these cases were sent for blood examination at the time of being boarded, but were in every case negative, save in two in which benign tertian trophozoites were found.

3. *Seasonal Prevalence.*—An examination of the seasonal prevalence on the three malarial fronts also showed certain differences.

In Salonica the malarial incidence rose in June and continued high through the summer months, reaching its maximum in September. October showed a slight decline, and the minimum was reached in January. In Palestine and Egypt the number of malarial cases rose in July, continued through the summer months, reached its maximum in October and November, and then dropped rapidly, reaching its minimum in March. In East Africa the seasonal prevalence was not marked, and showed only slight increases in January, March, April, and June.

The following table gives the numbers and percentages found:

	Salonica.		Palestine and Egypt.		East Africa.	
	No.	Percent.	No.	Percent.	No.	Percent.
May	13	6.1	2	3.7	3	7.7
June	42	14.3	3	5.6	5	12.8
July	33	11.2	7	12.9	3	7.7
August	43	14.6	6	11.1	3	7.7
September	58	19.7	7	12.9	3	7.7
October	35	12.2	12	22.2	3	7.7
November	23	7.7	11	20.4	2	5.1
December	8	2.7	2	3.7	2	5.1
January	2	0.7	1	1.4	4	10.3
February	6	2.0	1	1.4	2	5.1
March	12	4.0	0	0	4	10.3
April	13	4.8	2	3.7	5	12.8

The following suggestions are put forward to account in some measure for the seasonal differences.

1. *Climatic.*—Salonica, Egypt, and Palestine are non-tropical countries, and as such undergo marked variations in external temperature, depending on the time of year. In Salonica especially the winters are severe, and in Palestine and even Egypt the differences between the winter and summer temperatures are quite marked. East Africa, on the other hand, is tropical, the equator passing through British East Africa, and the theatre of war being situated directly south of this. For this reason there is very little difference in the winter and summer temperatures, and any coolness is dependent on the rains. These occur in the various parts of the country at different times of year. Thus, in the interior plains, the rains commence about October. In the highland plateau they are later, not appearing till December and lasting till the middle of April. On the coast the rains commence about June. Now, just as a certain temperature is essential for the breeding of mosquitos, so also is an adequate amount of water necessary for the depositing of the eggs. During the dry months the heat of the sun tends to dry up all collections of water, so preventing the eggs hatching. Also, the heavy rains are apt to wash away and destroy deposits of eggs, so that the mosquito has to wait till the end of the rainy season, when there is a plentiful supply of suitable water, before its eggs can be hatched out to the

best advantage. For this reason the seasonal prevalence of malaria alters for the various parts of the country, depending on the time of the rains.

2. *Conditional.*—By this is meant the alterations of service conditions in the increasing or mitigating the contraction of the disease. This especially applied to Palestine, where the rapid advance into the highly malarious country of the Jordan Valley in the summer of 1918, accounted for a very great number of the total malarial cases. Unlike Salonica, Egypt and Palestine were not wholly malarious; and in Palestine, where the majority of cases occurred, the incidence seemed to depend on the movements of the troops from a camp where antimosquito measures had been effectively taken into a fresh unprotected and more highly malarious district.

Salonica itself is a highly malarious country, notably the Struma Valley, where many miles of marsh land render satisfactory antimalarial measures quite impossible owing to the enormity of the task. Another factor was that in this theatre of war the campaign was less progressive, so that the incidence depended for the most part on the climatic conditions. This is indicated in the following table, showing the number of cases and the percentages contracted on the three fronts during 1915 to 1919 inclusive. It will be noticed that the years 1916 and 1917 show the highest malarial incidence, which declined markedly in 1918. During the autumn of 1915 a few troops only were disembarked at Salonica, and no serious operations were attempted that year. The year 1916 shows increased activity. Large numbers of reinforcements arrived, and an advance was made into the Struma Valley. In this highly malarious part, the incidence during the summer and autumn months was very high. In 1917, more reinforcements arrived, and the advance, which had been held up for more than a year, recommenced. Monastir was recaptured, and fresh malarial country opened up. This year showed the maximum incidence. The incidence declined in 1918, when sanitary measures began to prevail, and more suitable country was occupied by the troops.

In East Africa the real offensive commenced with the arrival of General Smuts in the spring of 1916, and by the autumn of that same year the whole of German East Africa north of the central railway running from Dar-es-Salaam to Ujiji was freed from enemy forces. This part, though malarious, was not so highly infected as further south, where the next stage of the campaign was fought. This fresh country became the seat of operations in 1917, and the climatic conditions here, especially during the rains, could easily account for the marked increase of malarial cases. In fact, the climatic conditions were considered so deleterious that practically all European troops were replaced by Indian and East African native troops. This is probably the reason of the decrease in number for 1918, as only men from the British Isles are noted in these cases.

Palestine shows the most interesting figures. In 1916 the troops were advancing towards El Arish, in 1917 they were hung up before Gaza, and only in 1918 was made the big advance ending with the capture of Jerusalem and Damascus. It is generally observed that even in highly malarious countries stationary camps in time become fairly healthy, as modern sanitary methods have been found most efficient in combating the anopheles; stagnant water is either got rid of or treated, proper mosquito-proof beds and living rooms are constructed for the troops, and also the protective measures can be more easily enforced. The great advance took place early in 1918, and, once started, continued very rapidly. The troops had no time to take adequate protective measures against infection, suffering the more on this account. In addition, the country through which they were passing was highly malarious. Major Manson-Bahr, in describing the malarial incidence from *Laverania malariae* and *Plasmodium vivax*, shows that in the eastern sector from the Jordan Valley to Jerusalem, during the summer of 1918, the benign tertian epidemic commenced the beginning of June, and reached its maximum of 340 cases a week on July 13th. The malignant tertian epidemic commenced later and was very severe, reaching its maximum of 1,800 cases a week on October 12th. In the western sector from Jaffa to Ludd the benign tertian epidemic was the more severe, and reached its maximum of 850 cases a week on August 3rd.

It was followed by a less severe epidemic of malignant tertian, reaching its maximum of 600 cases a week on the same date as in the eastern sector.

I have to thank Sir Lisle Webb, Chief Commissioner to the Ministry of Pensions, for his kindness in allowing me to publish these cases, and for some of the statistics supplied to me.

A NOTE ON THE SURGICAL USES OF THE FASCIA LATA.

BY

CYRIL H. CUFF, M.B., B.S. DURH., M.R.C.S.,
NEWCASTLE-ON-TYNE.

THE extraordinary variety of injuries to all parts of the body which occurred during the war afforded to surgeons concerned in their treatment vast opportunities for exercising their ingenuity and invention. The application of the fascia lata to the repair of many of these lesions certainly received a great stimulus, and the results were on the whole eminently satisfactory. As one who, during the last eighteen months, has utilized fascia lata fairly extensively in different conditions, I venture to indicate some of its more obvious applications.

I. In the repair of, or as a substitute for, tendons and ligaments:

- Injuries in which there is loss of tendon substance, recent or old standing.
- In lieu of dividing and transplanting a healthy tendon, in order to reinforce a paralysed one, connecting these two by a fascial intermediary tendon.
- As a substitute for intrinsic or extrinsic articular ligaments—for example, the crucial (Hey Groves) and the internal lateral ligaments of the knee.
- As an auxiliary ligament—for example, in lieu of tendon fixation for a "dropped" foot—a Y-shaped fascial ligament may be employed; or in recurrent dislocation of the shoulder a fascial "sling" passed through the quadrilateral space may be used, or it may be passed through a hole drilled in the head of the humerus and the acromion process.

II. For clothing an area which has been deprived of its normal covering tissue.

- After the excision of adherent scars.
- In the abdomen, after extensive resections of the colon, to aid in "peritonization."
- In arthroplasties, interposed between the two raw bony surfaces (Murphy).
- As a sheath to protect a nerve suture.
- In gunshot or other injuries of the skull, where there has been extensive loss of substance of bone and dura mater prior to bone grafting.

III. To reinforce defects in the parietes of the chest, the abdomen, and of vessels.

- To cover in a lateral defect in a vessel wall.
- In repair of the urethra, after excision of stricture.
- In closure of faecal fistulae and ventral hernia, where parietes are deficient.
- In reconstruction of an intercostal space in hernia of the lung.

There are doubtless many other purposes to which this valuable tissue can be applied, and the above list only aims at giving some concrete idea of its scope.

Among the many little details that count towards success are the following: first, that the graft should be of

ample proportion and should be treated with the same respect as a bone graft; secondly, when used as a new ligament, the greatest care should be taken to imitate the anatomical attachments of its predecessor; and thirdly, that when used as a ligament, tendon, or to reinforce parietes, there should be no "slack" after suture is completed.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INCUBATION PERIOD OF SCARLET FEVER.

In view of the fact that in accordance with "A Code of Rules for the Prevention of Infections and Contagious Diseases in Schools," issued by the Medical Officers of Schools' Association, the incubation period of scarlet fever is given as "one to eight days, usually three to five days," I think, perhaps, the following instances in which the incubation period appears to have been ten days or more may be of interest. It may, of course, be said that they do not prove anything conclusively, but anyway they are in favour of the incubation period being longer than it is usually supposed to be.

1. Two children (M. and P.) travelled to a seaside convalescent home from London on February 9th with two other children who had recently been under treatment for scarlet fever. M. was taken ill with the disease on February 19th, and P. on February 24th. No other cases in the home on arrival.

2. Two children (T. and B.) travelled to a seaside convalescent home from London on February 2nd with a child who had recently recovered from scarlet fever. T. was taken ill on February 23rd, and B. on March 1st. Possible infection in the home.

3. Two children returned from their home to a private boarding school. The next day notice was received that a sister at home, with whom they had been in contact, had developed scarlet fever. The two children were immediately isolated, and developed scarlet fever, one nine days and the other ten days after returning to school.

4. A child was admitted to a private boarding school, and developed scarlet fever exactly ten days afterwards. So far as could be ascertained, there were no other cases in the school or neighbourhood.

5. In a convalescent home four cases of scarlet fever occurred under the following circumstances: F. C. arrived on January 27th, was taken ill on February 26th; E. D. arrived on February 3rd, was taken ill on February 22nd; T. C., an inmate, developed scarlet fever on February 26th; M. W. arrived on February 6th and was taken ill on March 12th.

6. In a convalescent home two children were taken ill with scarlet fever on July 31st; they arrived at the home, where there had been no other cases, on July 23rd; another child arrived on August 13th and was taken ill on August 22nd.

MEASLES, INTUSSUSCEPTION, AND APPENDIC-ECTOMY IN A BABY SEVEN MONTHS OLD.

A boy aged 7 months, breast-fed, was admitted into the Dorset County Hospital on November 29th, 1919. He had measles, but up to the previous day he had otherwise seemed well. On the 29th he passed a healthy motion early in the morning, and about 11 a.m. he seemed to be in pain. He vomited his feed at 1 p.m., and passed a green motion. He refused the breast during the remainder of the day, and had spasms of screaming and retching. At 7 p.m. he passed a blood stained motion with mucus. Shortly afterwards he was admitted to the hospital.

On admission the patient was a well nourished child thickly covered with the rash of measles. A hard mass could readily be felt to the left of the umbilicus. Under an anaesthetic an incision 2 inches long was made over the swelling. A finger could follow the swelling towards the left iliac fossa, and after a little manipulation that portion of the descending colon containing the apex of the intussusception was delivered into the wound, and by gentle pressure below its lowest point the intussusception was reduced with surprising ease. As each portion of the bowel involved was dealt with it was returned into the abdominal cavity until the ileo-caecal valve was reached. The appendix, abnormally long, was for half its distal portion very dark in appearance—almost gangrenous—thus apparently being due to its blood supply having been cut off. The appendix was removed. The caecum and ileo-caecal valve felt very thick and oedematous, and the peritoneal coat of the former was roughened. The child stood the operation well; there was no vomiting subsequent to the operation. He took his feeds well; these were restricted at first in amount and frequency. A small greenish stool was passed eight hours after the operation, and faecal matter began to appear in the stools in twelve hours.

The temperature, which was raised on admission, dropped to normal in a few days, and the wound healed by first intention. It was fortunate that the caecum and appendix could be pulled into a wound to the left of the umbilicus.

The combination of measles, appendicectomy, and a successful operation for intussusception of such a long position of the bowel, in a child of 7 months, makes the case perhaps worthy of record. I have seen the boy a short time ago, and he has been in perfect health since his operation.

B. W. GOWRING, M.D., M.R.C.S.,
Honorary Surgeon, Dorset County Hospital.

THE SARCOPTIC MANGE OF THE DOG IN MAN.

The lecture recently given by Professor Hobday before the combined meeting of the Royal Society of Medicine and the Central Veterinary Medical Society on the contagiousness of certain diseases of animals to man, recalls to my mind an instance five years ago when a pug dog, the subject of sarcoptic mange, transmitted the disease to a family of six people.

The little animal was a great pet, and became very badly infected before any treatment was adopted, the extent and nature of the disease not being realized. The dog used to lie against the people's legs in front of the fire, often for half an hour or more at a time, pressing himself against them, and each developed the infection, which was in the form of an extremely irritable rash, not unlike lichen planus in appearance. It lasted for about six or eight weeks, and did not disappear until after the skin disease on the dog had been taken in hand, treated and cured.

I am pleased to see that attention has been drawn in a medical gathering to the subject of the contagiousness of certain animal diseases to man, as I am quite sure that its importance ought to be more fully realized and lectured upon in the curriculum of the student.

Reports of Societies.

PUERPERAL SALPINGO-PERITONITIS.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, on March 3rd, with the President, Professor HENRY BRIDGES, in the chair, Dr. ALECK W. BOCKE read a paper on "Acute puerperal salpingo-peritonitis." He justified his modification of the name of a common disease as it emphasized the fact that the condition was entirely different from acute non-puerperal salpingitis in morbid anatomy, physical signs, and treatment. The morbid anatomy was largely determined by the anatomical position of the involuting tube and uterus at the time when the inflammation occurred; suppuration thus tended to be primarily extra-pelvic and abdominal, causing abscesses above the brim of the pelvis. Further points were the early obliteration by adhesions of the pouch of Douglas, secondary ovarian infection, secondary cellulitis of the upper portion of the broad ligament, and the arrest of uterine involution so long as infection was unrelieved. The cause of puerperal salpingitis was, he stated, an organism (streptococcus in three of the tubes examined) which either ascended from the uterus, probably the commonest mode of infection, or which had existed dormant in the tube from pregnancy, as proved by a case of salpingitis following Caesarean hysterectomy where the tubes were absolutely normal, or which provoked an exacerbation of a pre-existing salpingitis during the puerperium. The symptoms were those usually found in acute peritonitis of the lower abdomen, and were not particularly noteworthy. The chief points were that the temperature and pulse tended to be high, more so, for instance, than in acute appendicitis; the lochia was usually unaltered; and retention of urine or painful micturition might denote an extensive secondary cellulitis. The physical signs required careful examination. On examination of the abdomen the initial tenderness was at a point just below and external to the umbilicus; the fundus uteri was at first median and rose about two inches above the

symphysis, and pressure on the fundus soon caused pain; there was pronounced tenderness above the inner part of Poupert's ligament, indicating secondary cellulitis; after an interval there was rigidity and tenderness of the lower abdomen; any hypogastric tumour, apart from the fundus uteri, was due to omentum and coils of adherent intestine; and, later, asymmetry of the fundus uteri was caused by secondary cellulitis. On vaginal examination there was an absence of physical signs except general tenderness, but later a mass could be felt high up in the postero-lateral fornix, due to the ovary surrounded by the adherent coils of intestine. By the rectum, the formation of a tubo-peritoneal mass was more usually felt, and at an earlier date, than by the vagina. The treatment was early laparotomy. The chief reasons for early operation were the prevention of extending peritoneal abscesses; the anticipation of the formation of dense adhesion; prevention of infection of the ovary, which occurred early and was difficult to eradicate apart from oophorectomy; prevention of a spreading secondary cellulitis; and to enable the subinvolved uterus to undergo involution and thus prevent a chronic uterine hypertrophy.

Dr. GEORGE EVANS read a paper on "A study of the condition of the arteries in a uterus removed twenty-four days after delivery." He referred to the work of A. Helme, who showed in 1887 that fatty degeneration did not occur in the normal involution of the rabbit's uterus; but more recently James Goodall had established the opinion that fatty degeneration did occur in normal uterine involution. Dr. Evans's paper was founded on a specimen prepared by Gaskell's method and cut frozen, so that the cells retained more nearly their normal form, and any fat present was not dissolved out of the tissues. He found that the histological picture was that of normal arterial involution, as it occurred elsewhere in the body under physiological conditions; and there was no fatty degeneration of the muscle fibres in the medial coats of the arteries. His submission, therefore, was that the question of the presence or absence of fatty degeneration in the media of the vessels in the puerperal uterus was not as yet definitely settled.

Dr. RUSSELL ANDREWS, Dr. HERBERT SPENCER, Dr. HERBERT WILLIAMSON, and Dr. A. C. PALMER showed a series of pathological specimens.

TREATMENT OF UTERINE PROLAPSE.

At a meeting of the Edinburgh Obstetrical Society, held on March 9th, with Dr. WILLIAM FORBES, the President, in the chair, Dr. SAMUEL CAMERON (Glasgow) read a paper on the surgical treatment of uterine prolapse. He referred to the fact that the plastic operation had developed within the past twenty years. Nowadays he never used methods of abdominal fixation, and believed that adequate results could be obtained by plastic means. He employed three operations, the choice being mainly influenced by the age and by the physical condition of the patient, and also by the number of living children which she had. When the patient had several healthy children, and was about the menopause, the interposition operation was recommended; but if she was a young woman, Fothergill's modification of colpo-perineorrhaphy should be the operation of election. In frail elderly women he practised an operation which he had devised. Within the past five years he had operated on 292 cases of prolapse. The interposition operation he had performed 136 times and, so far as records showed, these cases had remained cured. In doing this operation on a patient before the menopause he always carried out sterilization. He recorded one case in whom this precaution was not taken, and who subsequently became pregnant. The gestation continued to full time, when Caesarean section was performed, with the birth of a healthy child weighing 9½ lb. The uterus had expanded entirely at the expense of the posterior wall. It was interesting to note that the bladder had been pushed to one side, rendering access to the uterus easy.

The operation which he performed in frail elderly women consisted in amputation of the cervix by a circular method after a flap of vaginal mucous membrane had been reflected up for a short distance. An incision was then made in the perineum as for ordinary perineorrhaphy, and the incision was deepened until the vaginal wall was liberated to a fair extent. The cervical stump was pulled downwards and moored by sutures in the raw tissues of the vaginal wall and perineum. Thereafter the perineum was closed up in the ordinary way.

He had performed this operation twenty-four times and only one had failed, owing to non-union of the cervix with the vaginal flap and perineal tissue. The first case was operated on over four years ago. His fear when he first performed this operation was that the patients might develop pyometra, but so far this had not happened.

The PRESIDENT had never performed the interposition operation, which did not, to him, seem to possess any advantage. He believed that an extensive plastic operation was all that was required.

Dr. HAIG FERGUSON found that the extensive plastic operation as ordinarily practised gave excellent results, even with the worst cases of prolapse. He thought that Dr. Cameron's operation was associated with a distinct risk of pyometra, for one knew that even after ordinary cervical repair or amputation this result might follow.

Haemorrhage with Eclampsia.

Dr. FORBES and Dr. R. W. JOHNSTONE read a paper on a case of concealed accidental haemorrhage with eclampsia. The case was a primipara who had been well up till the eighth month of pregnancy, when without warning she was seized with pain in the abdomen and breathlessness. Soon afterwards vaginal haemorrhage appeared. On admission to hospital she was collapsed, there was considerable oedema of the trunk and lower limbs, and the urine was scanty and contained a large quantity of albumin. As the pulse rate increased, and toxic symptoms began to manifest themselves in a dimness of vision, sickness and a slowly increasing tendency to coma, Caesarean section was determined upon. At the operation the upper part of the uterus was deeply congested and haemorrhagic. It was most marked in the region of the right cornu, where the wall was deep purple. The same appearances were present in the adjacent broad ligament and Fallopian tube. The appearances suggested an obstruction of the right ovarian vein. The placenta was detached over its right half by a large retroplacental clot, whilst its left half was still attached to the posterior uterine wall. The child was dead. On subsequent examination the uterus showed the appearances associated with "diffuse utero-placental apoplexy." The muscular wall was ploughed up by haemorrhage, the muscular fibres showing a secondary degeneration. The placenta presented an interesting appearance. The detached portion had a deep purple colour and was distinctly marked off from the healthy area. Microscopically the separated area showed the signs of early infarction which have been described by Dr. Young, namely, coagulation in the intervillous spaces and congestion and crowding of the villi. The liver and kidneys showed the changes characteristic of eclampsia.

Dr. DOUGLAS MILLER read a report of a case of placenta praevia associated with post-partum eclampsia. The patient, a 6-para, had been bleeding intermittently for a month and more or less continuously for a week. She was almost moribund on admission. She was six and a half months pregnant. The urine contained a trace of albumin on admission. Delivery was carried out by version. Next day headache and epigastric pain developed, and there was a heavy deposit of albumin in the urine. Forty hours after labour she had a convulsion, followed by coma from which consciousness was not regained. Post-mortem examination of the liver and kidneys showed the changes characteristic of eclampsia. The placenta portion of the placenta was greatly congested.

It exhibited the features of recent red was consistent with the view that the toxæmia was dependent upon an absorption of poisons from the disintegrated portion of the placenta.

The PRESIDENT said that these cases seemed to lend support to Dr. Young's explanation of eclampsia. If this theory were correct, however, he wondered why toxæmia did not occur oftener.

Dr. CAMERON could not understand why one should have to deal so often with cases where there was obviously a partial detachment of the placenta or ovum, and yet there was an entire absence of toxæmia.

Dr. LACKIE asked Dr. Young how he would explain the cases where the amount of albumin remained stationary.

Dr. YOUNG referred to the work which had been done in other clinics, and which, along different lines, lent support to the view that a severe toxæmia might be dependent upon a

the absorption of the earliest products of tissue degeneration, a view which he had advanced in 1914. He cited especially the work of two French observers, who found that animals in which the uterine veins were ligatured for ten minutes died after a period of thirty to forty hours with signs closely simulating those of eclampsia. The fundamental point in his interpretation was that the amount of toxæmia varied directly with the degree of placental involvement. In some cases the toxæmia was slight, whilst in other cases it was severe. Even if the patient's life were not endangered there might be permanent damage of the kidneys. In support of his view he instanced the fact that Dr. Miller had found toxæmia of varying degrees in 60 per cent. of cases of placenta prævia.

PSYCHOLOGY OF HOSPITAL PATIENTS.

A MEETING of the Ulster Medical Society was held in the Medical Institute, Belfast, on March 10th, with the President, Dr. THOMAS HORSTON, in the chair. Mr. FULLERTON showed a case of deformity in a young child, and skiagrams of the case were thrown on the screen; the left femur was absent and the left leg was much smaller than the right.

Dr. W. CALWELL read "Notes on the examination of the mentality of patients in a general hospital." He referred to the exceedingly brief account given in the ordinary medical textbooks of the psychology of patients; a systematic and scientific case-taking was undertaken in some of the textbooks of insanity but was absent in those of general medicine. He described the later advances in cerebral physiology by Head and others, and the changes in psychology dating from Freud. A brief history was given, ending with Rivers's attempt to correlate the results of these two investigations with the manifestations of the psychoneuroses, especially as seen in the war. War experience supported Freud's mechanisms but negatived his sex-instinct predominance. Owing to the large amount of work in the practical application of psychology brought about by the war and to the general interest taken in it by the public, it was very advisable that medical men should know the principles. The lay psycho-analyst was already here, and would do more harm than the bonesetter, osteopath, spiritualist, and Christian scientist. Dr. Calwell gave a tentative scheme to enable students and medical men to make a psychological examination of a patient.

Dr. McKISACK and Dr. MARSHALL emphasized the necessity of making greater provision for these cases.

Surgery of Bones and Joints.

Mr. S. T. INNES then read a paper on some problems of orthopaedic interest exemplified by the surgery of bones and joints. He commented on the relative scarcity of such cases in the wards of general hospitals prior to the war, their prevalence subsequently, and the increased interest in this speciality generated by the work done for the benefit of the wounded soldier. There was thus not only a great extension in the type and number of diseases and deformities coming within the parview of the orthopaedic surgeon, but also many orthopaedic problems presenting themselves from day to day before the general surgeon. While this justified the claim of Sir Robert Jones that every orthopaedic surgeon should have a preliminary training in general surgery, it demanded as well that if the general surgeon was to exist as such in the future he must possess a training in the general principles of orthopaedics. The first problem dealt with was that due to fracture of the long bones. Excluding those fractures which were suitable for treatment by splinting, there was a smaller proportion demanding treatment by open operation. These might be subdivided into two main classes—(1) those requiring plating after the method of Lane, and (2) those requiring bone-grafting. Of these, Lane's method was more suitable for recent simple fractures with special deformities—for instance, spiroid fractures of the femur and tibia where accurate anatomical restoration was difficult to obtain by means of splints, and for simple fractures showing non-union due to the interposition of soft tissue between the fragments. Bone grafting, on the other hand, was essential for gap fractures where other operation, such as the step operation, was deemed inadvisable. Bone grafting was

rendered scientifically possible by the experimental work of Macewen, who in 1880 got tibial grafts to grow in a flail humerus, but to day it gained its main advocacy from America, owing to the work of Albee and his followers. A number of lantern slides of fractures treated by each of these methods was used to illustrate the importance of selecting a particular method of treatment for a particular condition of fracture. The paper was illustrated by a series of lantern slides.

Rebiefus.

THE HEALTH OF THE INDUSTRIAL WORKER.

Is The Health of the Industrial Worker? Professor E. L. COLLIS and Dr. M. GREENWOOD deal with the medical aspect of industry. As is pointed out by Sir George Newman in an introduction he has written for the volume, the ill health from which the worker in almost all trades and in all districts suffers is due for the most part to preventable maladies, and these in turn are largely attributable to the neglect of hygiene. The loss of time and energy thereby induced, though less impressive than that due to accidents and special occupational diseases, represents a much larger drain on industry. The economic side of industry is closely bound up with the medical side, for the most economical production can be obtained by employing a man only when he is at his best in mind and body, and under circumstances in which he can yield his maximum output of both.

No men better suited than the authors to the task they have essayed could be found, for their training and experience have been thorough, both on the practical and the theoretical side. The result of their efforts forms a compendium of the present state of knowledge which will prove invaluable, not only to the factory doctor, but to the welfare worker, the factory inspector, and the enlightened factory manager.

The book opens with an interesting historical summary of industry, and one cannot read without a shudder of the terrible conditions under which many industrial workers were compelled to labour a century ago. Thanks to more enlightened ideas and to industrial legislation, these conditions are now a thing of the past, but it is probable that few realize how much still remains to be done. The Report of the Ministry of National Service, issued last year, gave an inkling of the truth when it stated that only a third of all the men of military age in Great Britain could be classed as Grade 1, that is, as perfectly fit and healthy. In some industries, such as that of mining, the proportion was as high as 73 per cent., but in sedentary occupations, for example, tailoring, it was miserably low. Improvement in the conditions of industry on the lines indicated by the authors cannot fail to have a favourable influence on the physique of the workers.

In later chapters the authors deal with statistical methods and the health of the worker as indicated by vital statistics. A particularly valuable chapter treats of tuberculosis and industry. The effect of environment is discussed at some length, and it is pointed out that, whilst at ages over 35 the town dwellers die of phthisis at a much greater rate than the rural dwellers, the excess is far greater amongst males than amongst females. This excess is most marked at the age periods at which the largest proportion of urban males are industrially employed, and the smallest proportion of industrial females—the age of married life. The authors surmise that industrial employment is a great factor in producing the difference, but they give reasons for thinking that, as a rule, the deleterious influence of factory life acts through the home environment. Vitality is lowered by adverse factory conditions, and the men in consequence succumb to evils associated with the home; whilst the women, who have not been rendered specially susceptible, escape. The incidence of another disease, cancer, likewise appears to be related to industrial conditions. The authors point out that the

¹ *The Health of the Industrial Worker.* By E. L. Collis, B.Ch., M.D. Oxon., M.B. C.P. Lond., M.R.C.S. Eng., and M. Greenwood, M.R.C.P. Lond., M.R.C.S. Eng. Containing a chapter on Reclamation of the Disabled, by A. Collis, M.A., M.D. Cantab., M.R.C.S. Eng., D.P.H. Durh.; with an introduction by Sir G. Newman, K.C.B., D.C.L., M.D. F.R.C.P. London: J. and A. Churchill. 1921. (20vo, 8vo, pp. 459; 34 figures. 3s. net.)

sudden change which has taken place in the conditions of life consequent on the development of modern industry has been associated with a rapid rise of cancer mortality, and this rise is greatest where modern industry is most developed.

The practical aspects of factory work are treated of in useful chapters dealing with industrial activity and fatigue, with the causation and prevention of accidents, the feeding of the worker, and the provision of washing accommodation and cloak-rooms. The importance of adequate ventilation and lighting in the workshops is discussed at length, and many improvements are suggested. The industrial employment of women is dealt with in detail. In discussing the many obstacles to employment which have been suggested, the authors conclude that anaemia is benefited by regular occupation, whilst menstruation is not adversely affected by moderate physical work.

The book is for the most part very readable, and is lightened by occasional quotations from early writers. At times, it must be admitted, it is rather stiff reading, which the non-mathematical reader will find a little indigestible; but this defect, if defect it be, is almost inherent in the nature of the evidence it is desired to adduce. Occasionally, also, masses of tabular matter are printed which seem redundant. Take, for instance, the inadequately explained tables on pp. 366-372, dealing with labour turnover. However, these are minor blemishes, which do very little to detract from the many excellences of the book.

SURGICAL ASPECTS OF DYSENTERY.

MR. ZACHARY COPE has republished his Hunterian lecture in an amplified and extended form in a volume with the title *Surgical Aspects of Dysentery, including Liver Abscess*.² He has been encouraged to do this, he tells us, by the fact that the literature of the surgical aspects of dysentery is scanty, scattered, and not readily available. The result is an excellent little book, which covers the whole field of dysenteric disease very thoroughly. Whilst it is addressed primarily to the surgeon, the physician, too, would profit by reading it. Mr. Cope has no special axe of his own to grind, and the man who operates on every lump in the abdomen at sight will do well to take counsel of Mr. Cope, who is a restrained, conservative, and wise adviser.

Dysentery and its results had before the war mainly an academic interest. So many thousands of Englishmen, now safely in their homes, have suffered from this disease during the past six years that it behoves all of us who did not gain a first-hand experience of the subject in the East to repair the gap in our knowledge. For dysentery is essentially a disease which is not over in a day. Infection lirks behind; the smouldering fire is apt to break into a blaze.

The difficulty of diagnosing between an attack of acute oedematous colitis and appendicitis is well discussed. It is important to make a correct diagnosis, since operation on this type of dysentery is fraught with danger. We note that Mr. Cope prefers valvular caecostomy in chronic dysentery to appendicostomy, and thinks that it has a definite place in the therapeutics of this disease. Occasionally an open caecostomy may be called for, and even an ileostomy. Cases are quoted to illustrate the indications for these operations, which are only to be undertaken in special circumstances. In the section on liver abscess we are on more familiar ground; it is well written, and is illustrated by two admirable colour plates and some black and white drawings. The technique of needling the liver and of transpleural exploration is well described. The book is pleasant to read and convenient to handle.

APPLIED EUGENICS.

MR. PAUL POPENHOE, the editor of the *Journal of Heredity*, and Professor R. H. JOHNSON have conjointly produced a volume on *Applied Eugenics*,³ which admirably presents the eugenist position. The book is a veritable mine of

information: it contains twenty chapters and six appendices, and it is fully illustrated. The facts and theories upon which the eugenist bases his programme for racial betterment are clearly set out, and the means by which a superior type might be developed are fully indicated. In the earlier chapters the authors examine the contentions that environmental influences are capable of changing inherent characteristics, and that such changes can be transmitted in the offspring. In criticizing these views, the work of Galton on twins and statistical studies by Karl Pearson and others are utilized, and a chapter is devoted to the question of the modification of the germ plasm. The Lamarckian doctrine is discussed in relation to mutilations, diseases, results of use and disuse, and physico-chemical effects of environment, special attention being given to the problem of the influence of alcohol in the production of racial degeneracy.

Having developed the view that differences between human beings are due to heredity rather than the result of environmental influences, the question of the inheritance of mental capacities is approached. Here the psychopathologist comes in for a good deal of criticism. While we feel that he would have more to say in defence of his views than the quotations in this volume would seem to imply, yet in some instances there is undoubtedly a tendency to stress unduly the influence of environment in the production of mental disorder and to over-emphasize the possibility of prevention from this point of view. This being so, a little criticism of the too optimistic psychopathologist will do no harm.

Chapters are devoted to the consideration of the laws of heredity and natural selection, followed by an account of the origin and growth of the eugenic movement. Evidence is then brought forward as to the desirability and possibility of enforcing certain restrictions on marriage and parenthood. The classes of the community which could properly fall within the scope of such treatment are indicated, these being the insane, feeble-minded, epileptic, and criminal. The suggested methods of restriction are critically examined, and that of segregation is favoured as, amongst the coercive measures, the most generally practicable. Attention is given to the possibility of improvement in sexual selection, and the directions indicated in which it might become practically realized. Amongst other subjects discussed are the birth rate, race suicide, miscegenation between white and black, immigration, the effects of war on the race, and the defects and uses of the science of genealogy. Some of these questions are, of course, of more vital significance to the American people than to the European races. The influence, beneficial or the reverse, of current social trends on the aims of eugenics is discussed in relation to taxation, "back to the farm" movement, democracy, child labour, compulsory education, vocational guidance, minimum wage, bonuses, mothers' pensions, sex hygiene movement, prohibition, and celibacy of teachers. The concluding chapters are concerned with "religion and eugenics" and "eugenics and eutherics."

From this brief survey it will be apparent that this volume includes within its covers discussion on a wide range of social problems. However opinions may differ as to the methods by which these vital problems are to be solved, no one can afford to ignore their existence. The question of racial progress or decline should be the concern of every thoughtful citizen. There is an obvious need for an increasing number of "eugenically superior or desirable" persons in the community. Persons who will be capable of reproducing a type with the following characteristics: "To live past maturity, to reproduce adequately, to live happily, and to make contributions to the productivity, happiness and progress of society." The eugenist offers tentative suggestions as to the methods by which such a desirable end could be achieved; and an aim such as this is entitled to respectful consideration. In this volume the case for eugenics is scientifically developed and clearly and temperately stated. We can thus thoroughly recommend it to all those who are interested in the question of racial betterment.

CLINICAL RADIOLOGY OF THE HEART AND AORTA.

THE first edition of Professor VAQUEZ and Dr. L. BOURT's *Le Cœur et L'Aorte: Etudes de Radiologie clinique*, appeared in 1913, a second was called for five years later,

²*Surgical Aspects of Dysentery, including Liver Abscess.* By Zachary Cope, B.A., M.D., M.S. Lond., F.R.C.S. Eng. London: H. Frowde, and Hodder and Stoughton. 1920. (Demy 8vo, pp. 167; 19 figures, 2 plates. 12s. 6d. net.)

³*Applied Eugenics.* By Paul Popenhoe and Roswell Hill Johnson. New York: The Macmillan Company. 1921. (Post 8vo, pp. xiii.+459; 46 figures. 14s. 6d. net.)

and a third edition⁴ with additions, especially on pathological and senile dilatation of the heart, bears the date of May, 1920. This work is on much the same lines as, and supplements, *Radiologie des vaisseaux de la base du cœur*, by the same authors, which was reviewed in our issue of December 11th last (p. 896), and here again the 183 figures are reproductions of orthodiagraphic screen tracings and not of skiagrams. The radiological methods employed in studying cardiac and aortic disease are first described with a comparison of orthodiagraphy and telerradiography. The shadow cast by the normal heart in the various positions is then fully considered and the measurements thus obtained are illustrated by a number of tables and drawings, including one of the authors' pathophysiological conditions, beginning with valvular disease in diagnosing pericardial effusion are greatly diminished by the assistance of radiology; but it is not infallible, for pericarditis with a small effusion and a large heart may imitate cardiac hypertrophy, and conversely a dilated heart, especially as the result of alcoholic myocarditis, may produce a picture suggesting effusion. The decision whether or not Brauer's operation of cardiomyolysis should be performed can only, in the author's opinion, be determined by radiosopic examination. It is shown that the conditions necessary for the production of Broadbent's sign—systolic retraction of the chest wall between the eleventh and twelfth ribs at the back on the left side—are not only pericardial adhesions to the heart and the diaphragm but also to the chest wall in front; it may also be noted that the authors have observed this sign with widespread pleuritic adhesions without adherent pericardium.

The special characters of the enlarged heart of the aged are detailed, and it is pointed out that this condition may be found in persons who are comparatively young in years though the subjects of arterio-sclerosis and cardiac debility. The detection of aortitis is materially assisted and, indeed, in many instances made possible only by means of radiology. In making the diagnosis the measurements of the aorta are carefully taken and its pulsations, depth of shadow, and its contour are estimated; in so doing the influence of age must be taken into account. Orthodiagraphy renders it possible to watch the progress of aortitis, and to give a prognosis with greater accuracy than can be attained by the ordinary methods of physical diagnosis—for example, in cases of aortitis without dilatation, but with calcification, parts of the vessel, such as the descending aorta, that are normally invisible become obvious. The differential diagnosis of aneurysms of the thoracic aorta from other conditions, such as skeletal deformities, pulmonary consolidations, cysts, and tumours, is considered. This work, which is the outcome of extensive personal observation, closes with a chapter on the localization of projectiles in the heart and pericardium.

NOTES ON BOOKS.

A BOOK intended for "the use of medical students and practitioners" in India, as RAI BAHADUR JAISING P. MODI's *Elements of Hygiene and Public Health*⁵ professes on its title-page to be, ought to present a clear exposition of the general principles of sanitary science, and of the application of these to the circumstances of the country and people for whose benefit it has been composed and published. Judged by this criterion the work under notice, of which a second edition has been called for within a "short space of time," is admirably adapted to fulfil the office of an educational textbook and an instructive handbook for the guidance of all concerned in the adoption of measures for the preservation of health and prevention of disease and death. The general chapters are well arranged and written, and contain full and accurate information. The chapters relating to schools, hospitals, industrial occupations, meteorology and climate, food and infectious diseases, take into account Indian conditions, and more special chapters concern village sanitation, fairs, famine camps, and poor-houses. Practical instruction, founded on

a knowledge of the requirements of these various subjects, are laid down in full and feasible detail. Several appendices, including model by-laws, and directions relating to water supply conservancy and other sanitary measures, are added. Sixty-seven illustrations constitute a helpful feature of the book. The arrangement, printing, and indexing are worthy of commendation.

*The British Journal Photographic Almanac*⁶ for 1921 is well described in its subtitle as a photographer's daily companion. It contains a directory of photographic societies and similar bodies, but its special value to the practising photographer is the long epitome of progress written by the editor, Mr. George E. Brown, F.I.C. The material, which is arranged under a series of headings, including apparatus, printing processes, and colour photography, is handled in a masterly manner. Convenient features are the collection of formulae for the principal photographic processes in use, and the series of tables containing data to which the photographer often has occasion to refer. The price has been raised, but it is still very reasonable.

In *The World of Sound*⁷ Sir WILLIAM BRAGG has collected in book form the six lectures he gave to an audience of young people at the Royal Institution during the Christmas holidays two years ago. The volume includes many illustrations, diagrammatic and otherwise, explanatory of the text, and a number of dainty head- and tail-pieces and vignettes, allegorical in intention, from the pencil of Miss Audrey Weber. The lectures provide a very agreeable introduction to this branch of physics; the lecturer's scope and method may be gathered from his headings: "What is Sound?" "Sound in Music," "Sounds of the Town," "Sounds in the Country," "Sounds of the Sea," "Sounds in War." In publishing them Professor Bragg has done his duty by the many youngsters and grown-ups who were not fortunate enough to hear his words and see his fascinating experiments, and it is of interest to note that several of the experiments were repetitions, using the same apparatus, of those performed in the same room by Tyndall half a century ago. The last chapter shows how "almost everything we have discovered about sound has found some application in the war."

⁷ *The World of Sound*. By Sir William Bragg, K.B.E., D.Sc., F.R.S. London: G. Bell and Sons, Ltd. 1920. (Cr. 8vo, pp. 195; 93 figures. 6s. net.)

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE forty-third annual general meeting of this association was held on March 17th (St. Patrick's Day) at Pagan's Restaurant, when Dr. Bulger resigned the presidential chair to Major-General WALLACE KENNY, C.B., A.M.S.(R.), who presided over a large attendance of members. The Chairman of Council, Dr. W. J. CORBETT, presented the annual report, in which it was stated that during the past year no less than three ex-presidents had died, Sir Charles Cameron, C.B., Dr. Phineas Abraham, and Sir James Dick, K.C.B., formerly Director-General R.N.

The festival banquet took place the same evening, when upwards of 100 members and guests (including several ladies) sat down, with Major-General WALLACE KENNY in the chair. After the loyal toasts had been duly honoured (the whole company standing up while they sang "God save the King") the Arnott Gold Medal was presented to Sir Berkeley Moynihan for his great achievements in surgery. In reply to the toast, "Our Guests," Sir BERKELEY MOYNIHAN said that all medical men with laudable ambition desired three things—namely: (1) To make competent provision for themselves and their families in declining years; (2) to attain the good opinion of their confrères; and (3) to train younger men to do better than themselves work to which they had devoted their own lives. Nothing gratified himself personally so much as the kindly appreciation of his efforts to attain the last-named object. Continuing, he said that he was proud to claim as his countrymen so many who for generations had been among the foremost in art, in science, in research and professional attainments, to say nothing of those leaders in war and politics whose names were in the mouths of everyone during such times of stress as we had recently been passing through.

Other toasts were proposed by Dr. JAMES A. MACDONALD (President-elect of the Association), Dr. W. DOUGLAS, and Dr. GUBBINS FITZGERALD. The proceedings were much enlivened by songs and piano sketches.

SATURDAY, APRIL 2ND, 1921.

RESEARCH IN RADIOLOGY.

IN recording last week the circumstances of the lamented death of Dr. Ironside Bruce reference was made to the fact that evidence has accumulated supporting the opinion that a severe type of aplastic anaemia may be caused by the effects on the blood-forming organs of the more penetrating radiations, both from the x-ray tubes and from radium; the suspicion attaches more particularly to the most penetrating—the gamma rays. Very many of the early workers with the x rays suffered from a peculiar form of chronic dermatitis which, in not a few instances, developed malignant characters; mutilating operations became necessary, and the sufferer's long martyrdom often ended in death. The measures devised for protecting the skin from the rays greatly diminished the risks of this nature, but the suspicion then arose that constant working with radium or x rays had an injurious influence on the general health. Dr. Mottram, Director of the Research Department of the Radium Institute in London, ascertained that after a certain time definite blood changes occurred, the number of red corpuscles diminishing and the white corpuscles falling well below 4,000 in the cubic millimetre. The last report of the Institute directs that no nurse or attendant who habitually applies apparatus should work continuously for more than three months, and that this period should be followed by a change of occupation or a rest for another three months. It advises also that all the workers should have at least two clear holidays a week to be spent in the open air. It would appear that precautions of the same nature should be taken in dealing with the x rays.

The position is obviously very unsatisfactory; the precautions suggested are confessions of ignorance. Inquiry into the physics of both radium and the x rays has gone a long way, but the nature of the action of the rays on living tissues, healthy or diseased, is still very much a matter of guesswork, and the technology of the whole subject is in a backward state. The applications of radiology outside medicine are of growing importance; the x rays were used during the war for detecting flaws in the workmanship of aeroplanes, and are being applied to the examination of the internal structure of metals. It was, indeed, suggested a year ago that the memory of Sir James Mackenzie Davidson, who had himself suffered from the ill effects of the rays, could not be better commemorated than by the establishment of an institute for research and teaching in radiology. A Mackenzie Davidson Memorial Fund was accordingly established, and an appeal, signed by, among others, Sir J. J. Thomson, then President of the Royal Society, Sir Clifford Allbutt, President of the British Medical Association, Sir Robert Hadfield, recently President of the Faraday Society, and Mr. Bonar Law, was issued. To establish such an institute fully equipped to meet the needs of the metallurgist and the engineer, as well as of medicine, is an ambitious undertaking, and the increasing use of high tension x-ray tubes in hospital and private installations makes it urgently necessary to ascertain what precautions

can immediately be put into practice. It is, we are informed, proposed at once to appoint a committee to make certain investigations. It is hoped that the Röntgen Society, which did useful work in devising methods of protection early in the war, will join with the Electro-therapeutic Section of the Royal Society of Medicine and the British Association of Radiology and Physiotherapy in the nomination of such a committee, consisting of expert physicists, physiologists, and radiologists.

Dr. Robert Knox, who is secretary of the committee which last year appealed for the establishment of an institute, now proposes that the new committee of investigation should report on the equipment of x-ray and electrical departments with a special view to the protective measures to be employed, and should make recommendations for the guidance of the assistants in such departments, dealing in particular with the hours of work and the need for fresh air and change. But his proposals are also of a much more general nature, for he would instruct the committee to investigate the properties of x rays and the best means of controlling their action, and also the changes produced in tissues by x rays, and particularly the blood changes. Such a programme is too wide for any committee, and Dr. Knox himself perceives this, for he says that what is really required is the provision of research facilities on a large scale, including the equipment of an institute, and the endowment of research into the physical, technical, and biological properties of radium and x rays. It is true that the elements of such an institute exist in London. We have in the first place the Radium Institute; we have at the Middlesex Hospital a radiological department under the direction of a professor of radiology, who works in close association with the professor of physics and his department; we have also the research department of the Cancer Hospital, recently reorganized and extended under the direction of Dr. Leitch. It may prove to be possible as a temporary measure pending the establishment of an institute to draw up a programme of work to be divided between several institutions.

Hitherto the medical use of x rays and of radium has been far too empirical; we want to get down to basic principles, through the application of which the therapeutic use of these powerful agents may be guided, and their injurious effects prevented.

THE TRANSMISSION OF MEASLES TO MONKEYS.

THE prevention of measles is still an unsolved problem, for attempts to attain this end by strict quarantine are commonly frustrated by the infectivity of patients in the prodromal stage of the disease. Prevention by prophylactic inoculation is a theoretical possibility, but obviously it must be preceded either by the isolation of the virus or the elaboration of a satisfactory method of obtaining it in a pure form, whether or not it is definitely identified microscopically and culturally. Efforts to obtain the virus by cultural methods have so far failed to give positive results; and, though much work has been done by Hektoen, J. F. Anderson and Goldberger, and Sellards on the transmission of measles from man to monkeys, the results have been inconclusive. Blake and Trask, of the Hospital of the Rockefeller Institute for Medical Research, have therefore felt it desirable to carry out an extensive investigation to decide this question. They employed a method that promises the best

¹ F. G. Blake and J. D. Trask, junior: *Journ. Exptl. Med.*, Phila., more, 1921, xxxiii, 385-422.

opportunities for the successful transmission of the virus—namely, the introduction of a comparatively large amount of the material believed to contain the virus by the natural pathway of infection; accordingly unfiltered nasopharyngeal secretion from patients in the very early stage of the disease was injected intratracheally into monkeys (*Macacus rhesus*). The question whether the disease had been transmitted was decided, as in the clinical diagnosis of measles, by the appearance of the characteristic symptoms and lesions of the disease. Out of ten monkeys inoculated intratracheally eight developed symptoms closely resembling those of measles in man, after an incubation period of from six to ten days; this afforded presumptive evidence that the reaction in the monkeys was due to the virus of measles. That the reaction was not due to the common organisms of the mouth present in the unfiltered nasopharyngeal washings is shown by the occurrence of the same reaction after the inoculation of the fluid when freed from ordinary bacteria by filtration through a Berkefeld-N filter. The possibility that the reaction was due to filtrable toxic substances in the nasopharyngeal secretion of patients suffering from measles is also excluded by the successful transmission of the infection through six series of monkeys by means of emulsions obtained from the skin, buccal mucous membrane, and the viscera of these animals. Citrated whole blood from monkeys seven to thirteen days after intratracheal injection of the donor monkeys caused the symptoms of measles, but cultures of this blood made in various ways, aerobic and anaerobic, did not show any growth.

The incubation period in the experimental monkeys was usually seven days when the virus was introduced into the trachea, but after intravenous injection of citrated blood the interval was apparently shorter (four days); this difference, it is thought, may be explained by the elimination of the period that probably elapses between the introduction of the virus into the air passages and the invasion of the blood. The onset is attended by malaise, diminution in the leucocyte count, conjunctival injection, and by the appearance of small discrete hyperaemic macules on the labial mucosa and inside of the cheek, which eventually coalesce, and may or may not show the minute bluish-white centres characteristic of Koplik's spots. From one to several days, usually on the third or fourth day after the onset, a characteristic exanthem of maculo-papules appears on the skin, and as a rule first on the face; it is rarely as widespread or as thick as in man, but it runs a similar course; and by the sixth to the tenth day after the onset the animal is well. A careful microscopical examination of the skin, labial mucous membrane, and tongue showed an exact similarity between the changes in man and those in the experimental monkeys. The fact that the average duration of the incubation period in monkeys is three or four days shorter than in human measles may, it is thought, reasonably be explained by the large quantity of virus injected into the trachea.

The only conspicuous difference between the human and the experimentally produced measles is the absence of the respiratory complications in the experimental infection; the authors cannot at present explain this difference, but they argue that it should not be held to constitute a valid reason for rejecting the belief that the reaction observed in the monkeys is caused by the virus of measles. Further observations on the virus and on the problem of protective vaccination will no doubt follow from the Rockefeller Institute and its attached hospital.

BILHARZIA DISEASE.

WE seem now to have the story of bilharzia disease complete, at least in its broad features: The adult worm comes to maturity in man; the intermediate host is a fresh-water mollusc; man is infested again through the skin and can be cured by antimony. The disease has been one of the scourges of Egypt for at least 3,000 years; the late Sir M. A. Ruffer, in a paper published in our columns of January 1st, 1910, described it from the kidney of a mummy of the twentieth dynasty (1250 to 1000 B.C.). The disease is known to exist to-day in most parts of Africa, especially Egypt and the Cape, in Madagascar, Mauritius, Cyprus, the West Indies, Guiana, and Brazil. It is due, as is well known, to infestation by a trematode, *Schistosoma haematobium*, discovered by Bilharz in Cairo in 1851. The mature worm occurs in the portal system of man, and the usual course of events is that the male and female travel conjugated down the anterior mesenteric vein to the wall of the bladder, whence eggs find their way into the urine. Much more rarely the parasite attacks the kidney and the intestines. The egg, when it reaches the urine, already contains an active ciliated miracidium which, when the egg reaches water, is liberated. Leiper showed by systematic inquiry in Egypt during the war that the miracidia enter certain species of fresh-water molluscs (in Egypt *Bullinus* and *Planorbis*). They may be seen swarming round individuals of these species but avoiding other species; they quickly disappear into the snails and establish themselves in the liver; there they form sporocysts from which cercariae are eventually liberated and reach the water; they are free swimming bodies; they infect man through the skin or mucous membrane of the mouth and throat. Theoretically it would be possible to control bilharziasis by breaking the life-cycle at any point. Leiper suggested a campaign in the summer, when the canals and drains are low, against the mollusc intermediate host; this would call for operations on a large scale, and co-operation with the farmers and cultivators would be necessary. The suggestion made by Dr. Christopherson, in a paper published at p. 491, is that a great deal might be done not only to relieve suffering, but to prevent the extension of the disease, by placing facilities for treatment at the disposal of inhabitants of the country districts by travelling dispensaries. The value of treatment of the disease by intravenous injections of antimony tartrate is now well recognized by medical opinion, and the results are so excellent that in Egypt sufferers are spontaneously applying for treatment in large numbers. Drs. Lansbury and Coleman were able to report the results of 1,000 cases in our issue of February 26th, p. 299; they used injections of antimony tartrate given in the manner recommended by Dr. Christopherson a couple of years ago. It is very possible that other salts or preparations of antimony may prove more convenient, and Dr. Cawston is working on this and other aspects of the subject in Durban. Recently the Minister of Health for South Africa, Sir Thomas Watt, informed Dr. Christopherson that the authorities intend to bring the antimony treatment of bilharzia to the notice of all concerned.

THE NUTRITIVE VALUE OF LARD.

THE enormous quantities of pig fat converted into lard for human consumption may be judged from the fact that in 1912 the weight of lard exported from the United States alone was over 500 million lb. The importance of a knowledge of its nutritive value is obvious, and we need, therefore, make no apology for recurring to the subject. Since 1913, when McCollum and Davis started the examination of various fats for the presence of the accessory substance known as vitamin A, and found none in lard, it has been generally assumed that the pig, unlike other animals, is peculiar, and does not store this valuable

food factor in its fat. Osborne and Mendel, two years later, carried out a single experiment to ascertain whether this is due to the technical processes to which the pig's fat is subjected in preparation for the market, but found that their own product, "laboratory lard," was equally inadequate for growth. This experiment must be regarded as of little value, as no test with unheated pig's fat appears to have been made. The mystery why the pig should form an exception to other animals has now been finally cleared up by the work of Dr. J. C. Drummond and his colleagues. Their paper¹ contains much of technical interest in relation to lard manufacture, and, as we have previously pointed out, shows to what drastic treatment the fat is subjected in order to produce the white product which appeals to the purchaser. The experimental pigs were reared on various diets, some containing the fat-soluble vitamin and others destitute of it. The photographs of the carcasses when the animals were killed are striking and convincing. One remarkable feature in the pig is the considerable growth which takes place early, even on a diet destitute of the vitamin. This is to form the subject of further work. In all cases, however, growth ceases sooner or later; and thus the necessity for the vitamin is proved. It is well known that animals cannot synthesize it for themselves, but rely on the plant world for its presence, and the green portions of vegetables form the main source of supply. The pig is usually reared on toppings (wheat pollards) and whey, which are cheap, being waste products; both are practically destitute of the vitamin; their fat, even without treatment, contains none. But if they are grass-fed in addition, then they store the vitamin in their body fat. The low nutritive value of lard is therefore due to two causes: first, the erroneous feeding of the pig; and secondly, the destruction of any vitamin which might be present in the natural fat owing to its exposure to oxidation at high temperatures during its subsequent treatment. Reform is therefore called for in two directions: first, the farmer must be instructed to feed his pigs on a more natural diet; and secondly, the public must not insist on a product which appeals merely to the eye. The so-called refining of foods may often refine away a valuable ingredient. A striking illustration of this has been recently shown to occur by Dr. Zilva in reference to the fat richest of all others in vitamin A—namely, cod-liver oil. The discovery that this vitamin is destroyed by oxygen at elevated temperatures renders necessary a reinvestigation of the question whether vegetable oils are really destitute of the vitamin. Those on the market are; but here again processes of refining may be in part responsible for the result.

MALARIA IN ENGLAND.

THE malaria problem in England is interesting not only from the practical but from the historical point of view, and further light may be thrown upon it by a study of the part played by meteorology. This point was emphasized by Angus Macdonald,² who has published detailed temperature statistics for 1858-1860, the last occasion on which malaria is known to have prevailed extensively in England. The year 1858 was noteworthy for an exceptionally long and hot summer, the Registrar-General reporting: "The heat in June was so great that there was no instance since 1771 in which the mean temperature for that month had been exceeded." Malaria is indigenous in certain parts of England, and of the three English anophelines *A. maculipennis*, which is known to be present in nearly every rural district and in or near almost every town in England, is believed to be responsible for nearly all the cases of the disease. Since the war the interest in malaria in this country has naturally greatly increased, as many practitioners have had a large experience of the treatment of the disease both abroad and at home, and also because the

danger of contracting it from the presence of relapsing cases among soldiers returned from the East caused the disease to be made notifiable. Statistics, moreover, show that no fewer than one army pensioner in every thirteen is being pensioned because of malaria. The influence of temperature and humidity on malaria in England forms the subject of a valuable paper by Brevet Lieut.-Colonel C. A. Gill, I.M.S., in the *Journal of Hygiene* of January last, following his investigations on the same subject in regard to India. He considers that relative humidity, being at all times favourable, plays little or no part in determining the seasonal incidence of malarial infection in England; but the temperature factor plays an important part, since it limits the period during which malaria may ordinarily be acquired in the United Kingdom to the months of July and August. To test the accuracy of this view Colonel Gill prepared a map of England, differentiating the areas having mean temperatures during July and August of (1) 62° F. or over, (2) 61-62° F., (3) 60-61° F., and (4) under 60° F. The distribution of temperature during the hottest months of the year, as measured by monthly mean temperature, was found to be in some respects peculiar, and differed from the distribution which on general grounds might have been anticipated. The area showing a mean temperature during July and August of 62° F. or over is extremely small, and comprises a strip of country in Essex and Kent on each side of the estuary of the Thames and the lower portion of the Thames valley. Included also is a strip of country in the south of Hampshire, near the New Forest, together with the eastern portion of the Isle of Wight. The towns of Brighton and Clifton also belong to this area. Area 2, which is much larger, extends on the south from near Dover to the west of Bournemouth, while the northern boundary runs obliquely across England from a point on the east coast of Norfolk to the Bristol Channel near Cardiff. The western boundary runs due north from near Bournemouth, then turns west and runs parallel to the Bristol Channel, and ends in the neighbourhood of Ilfracombe. Belonging to this area are small districts surrounding Torquay, Teignmouth, and Plymouth. Area 3 consists of a strip of country lying to the north of and parallel to Area 2 except in the east, where the northern boundary diverges so as to include an area in the south of Yorkshire. The estuary of the Dee and a small district along the north coast of Wales also belong to this area, while a district around Shrewsbury, the south coast of Devon, and three small coastal districts in Cornwall are included. Area 4 comprises the remainder of England and Wales with the exception of Manchester and Aberdovey, and the whole of Scotland and the whole of Ireland with the exception of the city of Dublin. In this area the mean monthly temperature during July and August—the hottest months—never normally reaches 60° F. During the period 1917-1919, 404 indigenous cases of malaria were discovered in thirty-nine different localities in the United Kingdom, according to the statistics of the Local Government Board and the Ministry of Health. On allotting to their respective areas the localities and the number of cases occurring in each, it is found that 40 per cent. of the endemic localities and no fewer than 86.6 per cent. of the cases are included in the extremely small zone of Area 1, while 40 per cent. of the localities and 10.4 per cent. of the cases are scattered throughout the larger Area 2. There are eight localities, or about 20 per cent., and 12 cases in Area 3, while no endemic localities and no cases exist in the rest of the United Kingdom. Of the thirty-nine endemic localities, seventeen are situated on the coast, and if those are included which are less than 100 feet above sea level and are at the same time in close proximity to the coast, no less than 65 per cent. of the endemic localities exhibit the climatic conditions prevailing in coastal regions during the summer. All the remaining inland endemic centres are in low-lying situations close to

¹ *Lancet*, 1920, xiv, p. 742.
² *Lancet*, 1919, xiv, p. 100. On Malaria. December, 1919.

river valleys or marshland, such as the Fen district. Colonel Gill suggests, therefore, that the precise location of the endemic centres of malaria in England within the area of favourable mean temperature may be partly explained by relative humidity. It has been shown by James that in a number of places in England which harboured many carriers and numerous anophelines no new case of malaria arose ("paludism sine malaria"), and also that some of the new cases recorded arose in areas which harboured only one to two carriers and exceedingly few anophelines ("malaria sine paludism"). Colonel Gill thinks that the explanation of these two conditions may be found in the part ascribed to the temperature and humidity factors, as it is clear that in England, if the temperature during July and August is unfavourable to the transmission of malaria, the local incidence of the disease will not be affected by the presence of many human carriers and numerous anophelines; while, on the other hand, in areas where the temperature and humidity factors are favourable, the transmission of infection will be apt to occur, provided one or two carriers are present together with relatively few anophelines.

ALEXIS SOYER.

UNDER the title "Alexis Soyer, a Chivalrous Chef," Captain J. S. Taylor,¹ Medical Corps, United States Navy, gives a full and interesting account of the self-sacrificing efforts of the leading chef in London, who had presided for ten years over the kitchens of the Reform Club when, in February, 1855, he volunteered to go gratuitously to organize the feeding of the patients at Scutari. This was not the first occasion on which he had shown his public spirit, for during the Irish famine of 1846 he conducted an open-air kitchen outside the Dublin barracks, where between four and five thousand people were fed daily at a nominal charge, and facilities were available for double that number in his kitchen near the South Union Workhouse. His name was familiar on account of his popular shilling cookery book, his *Modern Housewife*, and the "relish" he invented. When he got to the Crimean war zone, with his staff of eight assistants, he worked wonders, for not only were the diets transformed, but far-reaching economies were effected. He was the originator also of the Soyer stove, a common object in every military camp at the present day. Miss Nightingale, to whom he was devoted, subsequently wrote: "His death is a great disaster. Others have studied cookery for the purpose of gormandizing, some for show, but none but he for the purpose of cooking large quantities of food in the most nutritious manner for great numbers of men. He has no successor. My only comfort is that you were imbued before his death with his doctrines and that the Barracks Commission will now take up the matter for itself." At the conclusion of the war, before leaving the Crimea, he bought the wicker carriage which had been constructed for the use of Miss Florence Nightingale in her ceaseless errands of mercy throughout the widespread area occupied by the besiegers of Sebastopol and brought it to England, where it is still preserved. The "Great Soyer," as he was commonly known in the Crimea, must have presented a remarkable appearance in the costume he adopted; in a dialogue between the *Times* correspondent and John Bull, who was supposed to have visited the camp, the question was asked, "Who is that foreign officer in white bournons and attended by a brilliant staff of generals—him with the blue and silver stripes down his trousers, I mean, and gold braid on his waistcoat and a red and white cap? It must be Pelissier?" The answer follows: "That! Why, that's Monsieur Soyer, chef de nos batteries de cuisine." Thackeray is supposed to have portrayed him in *Pendennis* (1850) as Alcide Mirobolant, who conveyed his love messages to his employer's

daughter, Miss Blanche Amory, in the language of culinary creations, but this would appear to have been a gross caricature of a noble personality.

OPHTHALMIC WORK IN EGYPT.

THE seventh annual report, for 1919, of the Ophthalmic Section, Department of Public Health, Ministry of the Interior, Egypt,¹ shows that the new patients numbered 76,525; nearly 50,000 operations were performed, and the total attendances of out-patients were 906,961. As the staff were short-handed during the year owing to the war, the work must have been very arduous, and the director, Dr. A. F. MacCallan, and his assistants are to be congratulated on the results of the year's working. The seasonal variations of the different organisms did not differ much from what has been observed and recorded in former reports; during the summer a vastly greater number of patients present themselves for treatment than in the winter. This is mainly due to the increased amount of acute conjunctivitis present in the summer; but neither atmospheric humidity nor differences in the level of the Nile seem to bear any relation to the increased incidence of conjunctivitis. Dr. MacCallan believes that flies do not play a great part in the transmission of eye diseases; he acknowledges that more light needs to be thrown on the habits of the flies of Egypt, and notes that an entomological investigation of these points is now being carried on there. The gonococcus is the main cause of the increase of acute cases of conjunctivitis, but it is curious that the upward trend of the gonococcal curve continues longer than that of the temperature; the maximum temperature is in July, while the summit of the gonococcal curve occurs in October. It is interesting to observe the marked differences between the gonococcal conjunctivitis of Egypt and that of Europe; in the latter the contagion is usually venereal in origin, but in Egypt it is acquired from eye to eye. In Egypt it is often met with in a subacute or chronic form, and the disease appears to be less destructive to the eye than is the case in England. Can these differences, the Director asks, be due to the fact that the organism of Egypt is not the gonococcus at all, or is it less virulent than the British gonococcus? An investigation of this question has been begun at Giza, and it is to be hoped that it may be continued. More than 12,000 patients examined during the year were found to be blind in one or both eyes, and 4,000 of these were completely blind. Signs of simple glaucoma were found in 2 per cent. of all cases seen during the year, the number of operations performed for this disease amounting to 749. Of senile cataract, nearly 1,500 cases were seen, but as so many of these eyes had been previously spoilt by the complications of trachoma and acute conjunctivitis, the number of extractions performed only reached the "modest" total of 364. Lastly, we may note that, as should be expected from the wealth of clinical material at its members' disposal, the Ophthalmological Society of Egypt is in a flourishing condition, and it has been affiliated to the Ophthalmological Society of the United Kingdom.

INTERNATIONAL RED CROSS CONGRESS.

THE tenth International Red Cross Congress was opened at Geneva on the afternoon of March 30th; the number of subjects set down for discussion is so large that it will be continued until April 8th. Reports on certain funds and on the allocation of the Nightingale medal will be presented by the International Red Cross Committee, which has arranged the order of business. Various questions arising out of the experiences during the recent war will be debated, in particular the insufficiency of existing conventions concerning prisoners of war (military and civil). Other subjects for discussion come under the general

¹ United States Naval Medical Bulletin, 1921, xv, No. 1.

¹ The Seventh Annual Report of the Ophthalmic Section, 1919. By the Director of Ophthalmic Hospitals. Cairo: Government Press. 1920.

heading of the relations of the various international Red Cross organizations to each other and to other philanthropic associations in peace as well as in war. The establishment of training schools for nurses and the organization of district nursing in peace will be discussed. A proposal will be made to revise the Geneva Convention in order to add to it a series of articles defining the status of ambulance aeroplanes and airships, and the protection which should be accorded to them when engaged in the transport of sick and wounded in time of war.

MATERNITY AND CHILD WELFARE CENTRES AND DAY NURSERIES.

In view of inquiries from local authorities and others interested, the Ministry of Health has issued a revised list, with index, of maternity and child welfare centres in England and Wales, including, for the first time, a list of day nurseries. The list contains the names and addresses of 735 centres and 140 day nurseries conducted by voluntary societies, and of 1,188 centres and 44 day nurseries conducted by local authorities. At about 150 of the centres special dental treatment is provided, while others have special arrangements for eye and ear treatment. The centres in the first part of the statement are primarily consultation centres for nursing mothers and children under 5, but some are fully equipped for ante-natal consultations. There are now separate lists for residential and non-residential institutions. The Ministry of Health advises that consultation centres should be reserved for healthy women and children, and that, where possible, treatment should be given at special treatment centres, which may be established at a hospital or combined with a school clinic, and may take cases from a number of consultation centres.

We publish a Current Note in the SUPPLEMENT this week giving the dates on which the several two-day and one-day Scientific Sections will meet at the forthcoming Annual Meeting of the British Medical Association at Newcastle-on-Tyne.

We regret to announce the death of Mr. R. J. Pye-Smith, F.R.C.S., Consulting Surgeon to the Sheffield Royal Hospital and Emeritus Professor of Surgery in the University of Sheffield.

We have to announce also the death of Dr. R. Murray Leslie, physician to the Royal Hospital for Diseases of the Chest, which took place in London on March 29th.

Medical Notes in Parliament.

Maternity Welfare Administration.

Statement by the Minister of Health.

In the course of the debate on the Consolidated Fund Bill, on March 22nd, Dr. Addison took up questions as to the position of the Government in regard to recommendations of the Washington Convention as affecting maternity welfare. Under Article 405 the authority to determine whether legislation should be initiated was the Crown and its executive. If the matter did not rest thus it would mean that a body meeting in Washington could compel the British Government to submit legislative proposals to Parliament against its desire. If the Government submitted proposals, the action must carry the assumption that the Government approved of it. On the other hand, members were aware that an opportunity would arise, and had practically arisen, for attention to be called to the decision of the Government. The proposals of the Washington Convention were that the Government should provide for the six weeks preceding and the six weeks following confinement; that during the first-named six weeks the woman should be compelled to be absent from work, and that during the six weeks following confinement, and while she was absent from work, the woman should be paid out of the public funds, or by a system of insurance benefits should be paid sufficient to provide for full maintenance, free attendance, and for a doctor or a certified midwife. These were the recommendations relating to employed women. There was in our own country a system doubly capable of dealing with these questions. They had an Insurance Act which provided maternity benefit for women who were themselves workers or the wives of employed contributors. They had parallel with that, and administered by local authorities, a system for giving assistance, advice, and so forth in connexion with maternity and child welfare generally. The Washington recommendation would cut right across that system, which had been gradually built up in this country far in advance of what had been done in any other country. That was one reason for not adopting the recommendations. The British Government had acted in advance of these recommendations with singular success and with much greater economy than such proposals would permit. In this country there would be 400,000 women who would be eligible for these benefits. The British system provided that not only the women employed, but the wives of employed contributors, although not themselves employed, should benefit. The Washington recommendations would automatically exclude 3,540,000 women who were the wives of insured persons but not themselves employed contributors. The recommendations would be applicable to only about one-ninth of the married women of a particular class in our country. The Government had done something for the remaining eight-ninths. If the recommendations were adopted and applied to the employed women only they would cost about £1,700,000 a year. A system of this kind could not conceivably be limited to this small section of women of the industrial classes. It could not properly be limited to employed women only, and this was of an impracticable character. So soon as the system was in operation the working man whose wife did not go out to work would say, "My wife is as much entitled to this benefit." That would apply to eight-ninths of the married women of this country, and would cost an additional 15 millions sterling. He did not think, in view of our other services, the country required an expenditure to anything like such an amount. A table which he had supplied to Captain Elliot showed that the average expenditure for maternity and child welfare was rather less than a penny in the rates, and the total provision out of the Exchequer was rather less than 1s. 5d. in the £. The total from the Exchequer was about £900,000, and the total for all authorities a little less. There was now established a great system of maternity and child welfare centres throughout this country—nearly two thousand of them, with about 3,500 trained nurses and visitors. They had established a large number of maternity beds in houses where women who lived under bad conditions could be properly attended to on payment of a nominal fee. It was a system which had developed on lines quite different from those of the Washington Convention. The results were brilliant; no other word was adequate to describe them. During the past two or three years there had been a conspicuous absence of a bad epidemic; people had been better fed than before, and since the war there had been a greatly awakened conscience on these matters. He asked the House to note the child death rate for London. In 1913 it was 106; in 1917 it was 104; in 1918 it was 108. In 1919 the rate fell to 85 and in 1920 to 75. The child death rate for the greatest city in the world had been brought down in that remarkable way.

Mortality from Tuberculosis.

Dr. Addison, on March 23rd, informed Captain Elliot that the total deaths during the past six years (from 1915-1920 inclusive) from all forms of tuberculosis were as follows: 54,295, 53,858, 55,934, 58,073, 46,312, 42,545. The death rate per hundred thousand of the population for the same years were as follows: 151.5, 152.9, 162.4, 169.4, 125.8, 112.8. The figures for the last two years were the most encouraging we have had since the inception of the national scheme for the treatment of tuberculosis.

University of London Site.—Sir W. Davison asked, on March 24th, whether the agreement by the Government to purchase from the Duke of Bedford some eleven acres at the rear of the

British Museum was made by the duke conditional on the land being used for the erection of new buildings by the University of London; whether there was a clause that, in the event of such buildings not being erected by April, 1926, the duke should have an opportunity of repurchasing the property at the price which had been paid for it by the Government; whether the Government were consequently precluded from using the site for any other purpose than for the erection of university buildings; whether the site had been definitely purchased by the Government subject to the above mentioned restrictive covenant, and whether a copy of the agreement would be laid on the table of the House of Commons. Mr. Baldwin replied that the agreement contained a clause under which, if before April 1st, 1926, the Government gave notice that they found it impossible to use the property, the vendor would have an option to repurchase it for the price given, and if he did not exercise the option, the restriction of the use of the site for the purpose of the university would be removed. It was therefore not the fact that the Government would be precluded from using the site for any purpose other than that of university buildings. Mr. Baldwin promised to inquire whether the duke's trustees would have any objection to the presentation of the agreement. Sir W. Dawson asked if it were not a fact that the Government was precluded from using the site for other than university purposes seeing that the duke had an option for repurchase if it were to be used for other than university purposes. He repeated the question whether the site had been actually purchased. Mr. Baldwin said he thought that it had been purchased. If the duke repurchased, the question of use for other than university purposes would not arise. If he did not repurchase the Government would not be precluded. In the improbable event of the abandonment of the scheme it would be for the Government of the day to determine whether to dispose of the site or to devote it to other purposes. Sir W. Dawson asked whether the Minister of Education was aware that in his letter to Lord Rosebery the statement was definitely made (in urging the university to give an early reply) that in the event of the university not requiring the site it was required for other purposes, would it be stated for what other purpose the Government required a site of eleven acres? No reply was given.

Propaganda to Check Venereal Disease.—Dr. Addison, replying to Captain Elliot, on March 23rd, said that in accordance with the recommendation of the Royal Commission on Venereal Diseases, the National Council for Combating Venereal Diseases had been recognized by the Government since 1916 as the authoritative body for the purpose of spreading knowledge and giving advice in regard to the question of venereal diseases in its varied aspects. During the years ended March 31st, 1919, and March 31st, 1920, grants were made to the National Council from the Exchequer amounting to £13,000 and £15,000 respectively, and the grant up to date during the current financial year amounted to £13,750. These grants had been paid in respect of expenditure incurred by the National Council in connexion with a campaign of publicity and education, by means of lectures, meetings, exhibitions, and press advertisements, and by pamphlets, posters, and other literature. The grants for the current financial year included a proportionate sum for administrative expenditure. No grants were made direct by local authorities to the National Council; but some of these authorities had made contributions to the local branches of the Council in aid of propaganda and educational work undertaken by those branches. Captain Elliot asked whether, in view of the recent recommendations of the Birth Rate Commission, the Minister of Health would see that steps were taken to persuade the two societies engaged in the disease to co-operate instead of being in competition. Sir J. D. Rees: Will the right hon. member be so good as to read with suspicion the reports of a professor who has reported that victorious England is ever thus together.

The Waiting Work of Appeal Tribunals.—A question by Lieut.-Colonel...

number varying from month to month. Since February 28th six tribunals had been sitting in London. Approximately 3,000 cases await hearing in London; of these 1,565 have been received by the tribunals during the last month. Up to the present time the average period elapsing between the date on which an appeal was received by the tribunal and the date on which it was listed for hearing had been (he understood) six weeks. Steps for setting up additional tribunals were under consideration.

Appeal Tribunal Cases.—Sir Gordon Hewart stated on March 22nd, in reply to Mr. Gwynne, that the total number of cases awaiting hearing by the pensions appeal tribunals for England and Wales was 7,350, of which approximately 600 were cases in which the appellants had already been afforded one or more opportunities of having their cases heard but had failed to attend. The tribunals for England and Wales were hearing cases which reached them at the end of January and in the early part of February last. Two extra tribunals had recently been set up, and owing to the continued large increase in the number of cases received, the appointment of further tribunals was under consideration.

Coroners' Remuneration Bill.—Mr. Lloyd George, on March 24th, informed Major Steel that the Government did not oppose the second reading of this bill, but it must take its chance with other private bills.

Ex Service Cases in Lunatic Asylums.—On an inquiry raised by Mr. Raper, on March 23rd, as to the detention of an ex service man in Claybury Asylum, Dr. Addison said that the patient was interviewed by a medical commissioner of the Board of Control and a medical officer of the Ministry of Pensions, and it was decided by the Ministry of Pensions after the fullest consideration that the man had not yet sufficiently recovered for removal to a neurological hospital. There were about 4,675 ex service patients in asylums in England and Wales, and their mental condition was constantly under review. Mr. Raper put it to Dr. Addison that as recently as December 3rd he had informed the House that so far as he could find out there was no definite information as to any ex service men suffering from shell shock being kept in pauper lunatic asylums. Dr. Addison believed the statement was still correct, but shell shock did not include all forms of mental disability. It might be that this man was originally sent to the asylum as suffering from shell shock.

Blind Persons Act.—Mr. G. Edwards asked, on March 24th, whether instructions had been given by the Customs and Inland Revenue to pension officers to oppose the grant of any pension in the absence of a certificate of blindness from an institution for the blind or other similar body; whether, in fact, any certificate from a medical man or other satisfactory evidence was not sufficient to justify the grant of a pension; whether the attention of the Ministry of Health was called to this matter by the Norfolk Local Pensions Committee in November last, with special reference to cases where medical certificates had been obtained stating that the claimants were too blind to do any work for which eyesight was essential; but nevertheless the pension officer had opposed the grant of a pension. Dr. Addison said that it was in pursuance of regulations made under Section 10 of the Old Age Pensions Act that the instructions for carrying out the Old Age Pensions Act were framed. These instructions required the pensions officer, in the absence of a certificate from an institution for the blind or similar body, to appeal against the allowance of any claim unless he was personally satisfied that the claimant was totally blind. Arrangements had been made in the Ministry of Health for assessing any medical evidence which was produced by the claimant, and, where such evidence was lacking or inconclusive, for medical examination of the claimant. He had received representations from the Norfolk Pensions Committee such as was indicated in the question and was looking into the whole matter.

Optical Glass Industry.—The position of the optical glass industry has been the subject of careful consideration in connexion with the proposed bill in the safeguarding of certain industries. This was stated by Sir Philip Lloyd Gream on an appeal that the trade should be made "a key industry."

Opium Cultivation in China.—Replying to Sir J. D. Rees, on March 23rd, Mr. Montagu said it was not proposed to make any change in the opium policy of the Government of India as a result of the recrudescence of poppy cultivation in China. The matter was now governed by the Hague Convention, under which as China had prohibited the import of opium, India was bound to prevent the export of Indian opium to China. Sir John Rees put it that the prohibition by China of the import of opium was merely an empty form. Mr. Montagu said the matter would be discussed by the Opium Advisory Committee of the League of Nations at the forthcoming Congress in Geneva.

Condensed Milk Draft Regulations.—Dr. Addison said, on March 24th, in reply to Mr. Doyle, he understood that the standards recommended by the Committee were not substantially different from those which were advocated by the majority of trade witnesses, except in the case of full cream unsweetened, where a somewhat lower standard had been adopted. He was prepared to publish the Committee's report if there was any general desire for it.

Grants for Health Services.—The grants paid to local authorities in London during the last completed year in respect of health services were as under: Tuberculosis, £49,195; maternity and child welfare, £39,765; venereal disease, £35,543; total, £124,501. The total expenditure in all these services combined was 24d. out of an average rate for London of 14s. 5d. for the year.

The Easter Recess.—The House of Commons was adjourned until Monday, April 4th.

THE annual meeting of subscribers of the Cremation Society of England will be held at the new address of the offices of the society, 52, New Cavendish Street, W., on Wednesday, April 13th, at 3 p.m., to consider the annual report of the Council and elect office bearers for the ensuing year. The valuable work of the Cremation Society was noted in our issue of February 12th. Among the distinguished personages reported by the Council to have been cremated during the past year were Sir William Osler, Sir Robert Morant, Dr. Cecil Lyster, Sir Henry Burdett, Sir Charles Matthews, Admiral Lord Fisher, and Lord Glenconner.

England and Wales.

A SURVEY OF SURGERY.

In an address to the students of the Leeds Medical School, on March 15th, Sir Berkeley Moynihan sketched the romance of the art of surgery from 2000 B.C. down to the present day. There was evidence, he pointed out, that such operations as circumcision and trepanning were practised more than two thousand years before Christ. Beyond these, however, nothing of any consequence was done surgically until the time of Hippocrates, who was born 460 B.C. After Hippocrates there was a big gap before any other notable figure appeared, and then there was Celsus, a dilettante patrician, who probably therefore did not practise medicine, but was merely a recorder of the work of others. Galen was the next great figure, and for nearly 1,500 years after him practically no progress was made. Then came the period of the anatomists; the real father of anatomy in modern times was Mondino, who lectured in Padua in 1315. Then there was Sylvius who inspired Andreas Vesalius, the greatest anatomist of all time. Another big gap in the progress of surgery followed, because nobody knew anything about pathology. The man who laid the foundation of modern surgery, himself the greatest of surgeons, was "that cantankerous, red-headed little Scotchman" John Hunter. He and Morgagni built the solid foundation of pathology on which the modern edifice of British surgery had been erected. But the world waited for something to make surgery safe, and it came with Pasteur. The revolution that had been wrought in modern surgery was due to Lord Lister, and to him alone. Lister had saved more lives than all the wars of all the ages had thrown away. All the modern operations owed their existence to the work which Lister did. There had been greater surgeons during the last thirty years than in all the centuries which preceded that period, and that was all due to Lister. In conclusion, Sir Berkeley Moynihan said that to-day the view prevailed that surgery had reached her destiny, and was now almost a finished art. He believed it was true. He did not believe that the mortality percentage would ever be much smaller than it now was, but he regarded that not as an end, but as a beginning. The surgery of to-day must not be considered as bearing only upon the art of surgery; it was an art which allowed for the discovery of the reasons why, in the whole science of medicine. They could look on it now as the key which had been made to unlock a great many closed doors. It was only just beginning its true function.

LEEDS UNIVERSITY.

The University Council has appointed Mr. R. J. Stewart McDowall, M.B., Ch.B. Edin., to the post of lecturer in experimental physiology and experimental pharmacology. During the war Mr. McDowall served overseas with the R.A.M.C. for nearly four years, of which two and a half were spent in the Sinai desert. Since demobilization he has been working under Sir E. Sharpey Schafer in the Physiology Department of the University of Edinburgh, and is lecturer in that department and clinical tutor in medicine at the Edinburgh Royal Infirmary.

FAREWELL DINNER TO DR. ALEXANDER STOOKES.

A representative gathering of Liverpool obstetricians and gynaecologists, with Professor Henry Briggs in the chair, entertained as their guest Dr. Alexander Stookes at dinner at the University Club on March 19th, on the eve of his departure from Liverpool to reside in Devonshire. Under the age limit Dr. Stookes has this year retired from active public professional service, which began in 1895 at the Maternity Hospital and in 1899 at the Samaritan Hospital for Women. In both hospitals as a surgeon he has done admirable work. After dinner appreciative references to Dr. Stookes and his work were made by Mr. Adam G. Rankine, Dr. T. R. Bradshaw, Dr. Glynn Whittle, Professor Wilberforce, Dr. Frances Ivens, Mr. T. H. Bickerton, Dr. Blair Bell, and others. The Chairman, on behalf of those present and of friends in Manchester, Leeds, and Sheffield, who subscribed to the gift, presented Dr. Alexander Stookes with a cheque. Dr. Stookes, in expressing his grateful thanks, spoke with confidence of the

younger generation, whose advancement should be assisted by the retirement of the seniors in due season. He had passed through many happy days in Liverpool, and he looked forward to many more in Devonshire. It was a source of delight to know that he took with him the good wishes of so many friends. At the close of the happy evening Miss Ivens proposed the health of the Chairman. The secretarial duties of the dinner were ably carried out by Dr. Norman B. Capon.

INSTITUTIONAL TREATMENT OF TUBERCULOSIS.

The Public Health Committee submitted to the last meeting of the London County Council a report on the treatment of tuberculosis in London, particularly with regard to the method of selection of patients for institutional treatment, the regrading of the institutional accommodation available, and after-care. It has been found desirable that all patients recommended for institutional treatment, whether insured or uninsured, should if possible first pass through a period of observation in hospital beds, and the reservation of 250 such beds at the Brompton Hospital and of 75 at the City of London Chest Hospital has been arranged. The patients occupying these beds will be watched by the tuberculosis officers of the staff of the county medical officer. The average duration of stay in the observation beds will be from two to four weeks. The value of the observation bed is stated to have been confirmed by an observation of 158 cases sent for diagnostic purposes during 1920 to the hospitals just named. Of this number, 124 (78 per cent.) were reported as not suffering from tuberculosis, and of the 34 cases diagnosed as tuberculosis 10 were considered to be arrested cases not requiring active treatment. The total provision of institutional accommodation, including these observation beds, is for 2,550 beds—1,800 for adults and 750 for children. The 1,800 adult beds are graded into observation and emergency beds, beds for early cases, for moderately advanced cases, for far-advanced cases, for surgical cases and for training. The number of beds for early cases (300) is reduced in conformity with the stricter definition proposed by the Ministry of Health of what should be regarded as a true sanatorium case; the moderately advanced cases (500 beds) are selected patients who have been found by careful observation to be likely to gain material benefit from institutional treatment; the provision for far-advanced cases (400 beds) is subject to alterations made by boards of guardians and the Metropolitan Asylums Board; the 100 training beds are at farm colonies and similar institutions, and are provided only for ex-service patients. The estimated expenditure on the tuberculosis service for 1920-21 is £632,970, of which rather more than one-third is borne by the rates. Representations are to be made to the Ministry of Health as to the desirability of instituting an inquiry into the steps which should be taken to provide suitable employment for tuberculous members of urban populations, and as to the importance of an early decision upon the constitution and functions of care committees. It may be noted that the Greenwich Borough Council proposes to establish, under the medical supervision of the tuberculosis officer of the local dispensary, a centre for the training and employment of tuberculous patients in suitable occupations.

SOUTH-WESTERN OPHTHALMOLOGICAL SOCIETY.

A meeting of the South-Western Ophthalmological Society took place at Bristol on March 9th, and was fairly well attended. In spite of the large area covered by the society members were present from Plymouth, Newport, Weston-super-Mare, and other districts. Cases were shown at the Bristol Eye Hospital in the morning, and after lunch Mr. R. J. Coulter opened a very interesting and rather heterodox discussion on "Some squint problems." He made a demand for a simpler operation than is at present customary. The honorary secretary of the society is Mr. E. H. E. Stack of Bristol.

VENEREAL CLINICS ARRANGEMENTS FOR LONDON.

At the meeting of the London County Council preceding the Easter recess sanction was given to a renewal of the arrangements for the diagnosis and treatment of venereal diseases in London. For the last four years the Council has joined with certain neighbouring county and county

borough councils for the common utilization of the facilities afforded by a number of the London hospitals. The scheme has been found to work well, but the Council now desires to make modifications in it without the delay incurred in obtaining the consent of all the participating authorities. During the past year the number of patients' attendances has been 430,000, a considerable increase on previous figures. A venereal clinic has been opened at the Royal London Ophthalmic Hospital, the first to be established at an ophthalmic hospital in London. The estimated expenditure of the Council and all the participating authorities for the coming year is £126,583, of which three-fourths are met by Government grant. No increase is proposed in the amounts—£3,500 and £5,000 respectively—allocated for publicity arrangements and for drugs. A joint inspection of the clinics has recently been undertaken by Dr. F. N. K. Menzies and Brevet-Colonel L. W. Harrison, and a report is to be made to the Council at an early date on the extension of the facilities and increase of efficiency of the clinics.

Scotland.

TUBERCULOSIS SCHEMES IN EDINBURGH.

At a meeting of the Edinburgh Town Council last week a long discussion took place on a recommendation of the Public Health Committee to terminate the arrangement as to consultations with Sir Robert Philip and Dr. James in connexion with the city's tuberculosis scheme. A letter was read from the secretary of the university protesting against any undue haste in deciding a matter which might affect the interests of the university. It appears that the agreement made in 1914 provided that, in the event of the university establishing a chair of tuberculosis, the city corporation would give all reasonable facilities for teaching in connexion with the work carried on in the corporation's hospital, dispensary, and farm colony, and for the purpose of research. The university did establish a chair of tuberculosis and Sir Robert Philip was appointed professor. The Public Health Committee would appear to have been moved to terminate the agreement with Sir Robert Philip to act as consulting officer by the fact that experience showed that the occasions for making use of his services were few or none. A letter was also received from the Royal Victoria Hospital Trust asking that more time might be allowed for consideration, and this view was supported by the Lord Provost. Eventually, however, the recommendation of the Public Health Committee was adopted by 22 votes to 14. As the matter stands at present it would seem that the corporation and the Edinburgh Insurance Committee, which contributed to the cost, will cease to have the advantage of the services of Sir Robert Philip and Dr. James as consulting experts, but that the professor of tuberculosis in the university will continue to enjoy facilities for teaching and research at the institutions maintained by the corporation for tuberculosis.

MEAT INSPECTION IN SCOTLAND.

A report by Lieut.-Colonel Leighton, Medical Officer (Foods) Scottish Board of Health, on the subject of a uniform system and standard of meat inspection in Scotland has been now issued.¹ This report (which also embodies the reports of three committees of experts appointed by the board to assist Colonel Leighton in his inquiry) is of importance to public health officials and others interested in the subject of meat inspection and its bearing upon the health of the people. A survey is made of the conditions obtaining throughout Scotland in connexion with the administration of slaughterhouses and the inspection of carcasses, and these conditions are subjected to critical examination. The reports of the three committees deal respectively with (a) problems of general administration, (b) difficulties peculiar to rural areas, and (c) proposals calculated to secure uniformity in methods of inspection and in standards of judgement. The latter contains a complete scheme of instructions to meat inspectors as to the method of procedure to be followed in the examination

of carcasses and the standards to be observed in the passing or condemnation of the meat. This is the first scheme of the kind that has been drawn up and published in the United Kingdom.

POST-GRADUATE MEDICAL TEACHING IN GLASGOW.

For many years post-graduate instruction in medicine has been given in several of the hospitals in Glasgow, but it was only in the early part of 1914 that a special endeavour was made to bring together all the institutions and hospitals for the purpose of organizing a permanent comprehensive scheme of post-graduate teaching for Glasgow as a whole. Owing to the intervention of the war little progress was made until 1919, when an emergency post-graduate course was organized and carried on in the summer and autumn. The course was highly successful and the committee in charge felt justified in recommending that a permanent scheme should be instituted. Such a scheme was adopted on March 2nd, 1920, at a joint meeting of the Faculty of Medicine of the University of Glasgow and the General Committee for Post-Graduate Medical Teaching which had been appointed in 1914. The various teaching institutions and teachers taking part in the scheme constitute an association the business of which is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, K.C.B., M.D., and the vice-chairman Sir Hector C. Cameron, C.B.E., M.D. To inaugurate the scheme the board arranged a series of weekly demonstrations for practitioners extending from November last till May of this year; the number of practitioners taking advantage of the series is satisfactory. For the ensuing summer and autumn the board has arranged a comprehensive course of instruction for medical practitioners extending from May till October. Most of the hospitals in Glasgow are taking part in it, and the classes as far as possible have been arranged so that a practitioner, if he so desires, may occupy the greater part of each day in attending classes. The classes are open to all qualified medical practitioners, and will be conducted independently of the undergraduate courses. A practitioner may enrol for one or several classes, and may attend for one or more months as desired. These classes have been specially designed to meet the needs of general practitioners, but the board has also had in view the provision of facilities for young graduates and others who may wish to obtain a closer acquaintance with hospital work in one or other of its branches and who are prepared to give the necessary time. Arrangements have been made whereby a limited number may become attached to wards or out-patient departments as clinical assistants for definite periods in children's diseases, mental diseases, tuberculosis, or venereal diseases. They would work under the direct supervision of the physician or surgeon in charge and carry out such detailed investigations as directed. It has long been felt that Glasgow, in the midst of such a vast industrial population, with its abundance of clinical opportunities, should become one of the leading centres of post-graduate medical teaching. The Board of the Glasgow Post-Graduate Medical Association presents to the medical profession this year its first organized scheme of teaching. Syllabuses giving full information concerning the classes and clinical assistantships may be had on written application to Dr. A. M. Kennedy, Secretary, Post-Graduate Medical Association, University, Glasgow, or by applying personally at the various hospitals which are taking part in the scheme.

GLASGOW CANCER HOSPITAL.

At the annual general meeting of the Glasgow Royal Cancer Hospital on March 23rd, Sir George T. Beatson, senior surgeon to the hospital, presided. After referring to the decision of the directors to reopen the chemical branch of the research department, which was closed during the war, and pointing out that the funds of the research department were kept separate, he strongly appealed to the public for financial support. Like other voluntary hospitals, they had suffered from the stress of war conditions. The annual report stated that during the year the directors had seen their way to reopen the research department on a working basis again, but the work to be carried on would be confined to the chemical department of research. In

¹ To be obtained direct from H.M. Stationery Office, 23, Firth Street, Edinburgh, or through any bookseller, price 4s.

connexion with the biochemistry of cancer, they had appointed Mr. A. N. Currie to carry on certain investigations. At present this was the only branch of research that funds allowed of restarting, but it was a very important department. Of the 128 cases treated in 1920, 57 were males and 71 females. During 1920 there were 66 deaths in the hospital—31 males and 35 females. The majority of the 128 cases were inoperable, but for some of them surgical operative measures were possible and of a hopeful nature. In the treatment of the inoperable group radiation had been the procedure mainly relied on, and this had been carried out by α rays rather than by those of radium, whose field of application was being more narrowed down as experience was gained in its use. The hospital was indebted to the West of Scotland Radium Committee for a supply of radium emanations for treatment.

MATERNITY AND CHILD WELFARE.

At the annual meeting of the Lauriston Home for Maternity Rescue Work, Edinburgh, held on March 15th, the annual report was presented by Dr. J. Haig Ferguson. Sheriff Crole, K.C., who took the chair, after discussing the need for such a home, remarked that the Carnegie Trustees had some time ago offered to establish a centre for child welfare and maternity work. Nothing had yet been done, but the offer was still open, and some of those who were interested in the matter were prepared to formulate a scheme for submission to the trustees. In giving an outline of the proposals, the chairman said that the Lauriston Home would form an integral part of the scheme, and he suggested that something might be done under the joint auspices of the University of Edinburgh, the Town Council, the Royal Infirmary, and the Royal Maternity Hospital. A better maternity hospital was needed, and the present building might be made use of in connexion with the proposed child welfare scheme.

Correspondence.

THE MINISTRY OF HEALTH MEMORANDUM ON ENCEPHALITIS LETHARGICA.

SIR,—I fear that a slip in proof reading, for which I accept responsibility, led to the date 1658 appearing in this memorandum with its last two figures transposed, and also to the name of Ozanam being printed as Ozanann. I should be glad for space to thank Dr. F. G. Crookshank for both corrections and for his historical notes.

Dr. Crookshank's other criticisms of the memorandum are governed by his opinion of the stress which should be laid on the association of encephalitis lethargica with influenza. In objecting to the statement that "no direct relation has been established" between these two diseases, he seems, however, to read more into the words quoted than the ordinary reader would be disposed to do. Typhus and relapsing fever—to take an instance where the facts are much better known and proved—are both spread by the same agency of infection, while epidemics of the one are often most closely associated, both in time and in locality affected, with epidemics of the other. This does not, however, make it incorrect to say that no direct relation exists between typhus and relapsing fever; they are distinct pathological processes, and either disease can occur independently as an epidemic.—I am, etc.,

G. S. BUCHANAN.

Whitehall, S.W., March 26th.

SIR,—It appears, on further inquiry, that the paragraph of the Ministry of Health's recent memorandum lately criticized by me in your columns (March 26th, p. 478) is really the *imago* of a paragraph to be found in Dr. Bassoe's paper on "Epidemic encephalitis," printed in the *Journal of the American Medical Association* for April 5th, 1919.

Dr. Bassoe, who makes no claim to historical authority, derived his information from an intermediate source, and selected his references, not so much with a view to proving the anterior occurrence of encephalitis lethargica, as to showing the epidemiological relation between prevalences of encephalitis and of influenza.

It is therefore the more surprising that the Ministry, while copying Dr. Bassoe's paragraph and adopting literal

inaccuracies therein, should have added the grossly incorrect allusion to Willis and suppressed Dr. Bassoe's pointed and valuable references to "grip" and "fièvre catarrhale."

Had these references been not suppressed, the paragraph would have been far less exposed to criticism. But then the tenure of the official attitude concerning influenza and epidemic encephalomyelitis would have required no little dexterity.

It is, I think, in the true interests of epidemiological research that attention should be drawn to the manner in which this recent memorandum of the Ministry has been prepared, for much in it is open to substantial criticism besides the points to which I have alluded.—I am, etc.,

London, W., March 23rd.

F. G. CROOKSHANK.

ACIDOSIS AND ALKALOSIS.

SIR,—Dr. J. S. Haldane's review on the physiology of respiration, renal secretion, and circulation is of great interest; but I do not think he quite does justice to many workers in this field when he charges them with "failing to interpret rightly a diminution in the so-called 'alkaline reserve' of the blood," and, further, states that they had quite wrongly identified diminution in "alkaline reserve" with acidosis. No worker, so far as I know, has really confused the alkaline reserve of the blood with its hydrogen ion concentration. The confusion, if such exists, is purely a question of terminology.

Naunyn introduced the term "acidosis" for the formation in metabolism of large amounts of non-oxidizable organic acids (I quote from Magnus Levy's article in *Von Noorden, Path. des Stoffwechsels*, 1906, i, p. 189). Oxybutyric acid formed the most notable example, but the excretion of lactic acid in diseases of the liver was considered one of several other examples. In this use of the word there was no suggestion that oxybutyric acid necessarily acted by making the blood acid; in fact, controversy raged for many years as to whether coma was produced in this way, or whether the acids were poisonous in themselves. It is fairly certain now that the latter is the correct alternative, aceto-acetic acid being the poisonous substance.

Barcroft was, I think, the first to give a more precise meaning to the term acidosis, being one of the earliest, if not the first worker, to investigate physiological conditions where it was necessary to draw a distinction between the alkaline reserve of the blood and its hydrogen ion concentration. He states (*Respiratory Function of the Blood*, 1914, p. 227):

Here let me explain my use of the word "acidosis" in reference to the blood. In the following pages it will signify the appearance of acids (exclusive of CO_2) abnormal in kind or perhaps only in quantity in the blood, or even a decrease in the bases present. By acidosis, then, I mean an increase of acid relative to basic radicals in the blood, CO_2 not being considered. By the term acidosis I will signify nothing concerning the final reaction of the blood, which is largely regulated by the amount of CO_2 present.

This was a natural extension of the meaning of a word which had been in general use for years previously. This definition was quoted in full and accepted by Hasselbalch (1916) and by Peabody in America in an early review of the subject, and it has been generally adopted up to the present time. The more explanatory, but at the same time more cumbersome, phrase, "diminished alkaline reserve," was introduced by Van Slyke and Cullen in 1917.

Recently, Dr. J. S. Haldane and Professor Benjamin Moore have used acidosis as signifying increased hydrogen ion concentration, and alkalosis as diminished hydrogen ion concentration of the blood.

Such a variation in the definition of a term is of no importance to a man working at the subject, as he soon realizes in which particular sense an author is using it; but it is very confusing to others, and it was in the hope of simplifying the position that, at the last meeting of the Physiological and Pharmacological Section of the British Medical Association at Cambridge, the suggestion was made, and was favourably received, that increased and diminished hydrogen ion concentration should be known as "acidaemia" and "alkalaemia" respectively, and that diminished and increased alkaline reserve should be known as "acidosis" and "alkalosis."

The point I would urge is that the actual nomenclature is of no importance, but let us all use the same one. If we

use "acidosis" and "alkalosis" in Dr. Haldane's sense, can he supply us with a short expression for "diminished alkaline reserve"? It would be as well if some authoritative body gave us a lead. I am sure we should all be prepared to follow it.—I am, etc.,
Woldingham, Surrey, March 19th.

E. P. POULTON.

GLANDULAR FEVER.

SIR,—Drs. Letheby Tidy and Morley are to be congratulated on the timely appearance of their article on this disease. I think it will be found to appeal to a large number of practitioners in this district (West Riding), and possibly in many other places, by enabling them to label definitely what I think has been a large—possibly very large—number of examples of the disease.

In consulting practice naturally one does not see many of these cases, but I have been interested in them for the past two years, during which period I have seen at least a dozen, mostly the children of doctors or cases in which, from the characteristic debility and tardiness of convalescence, the slow involution of the (often considerable) glandular enlargement, and the marked tendency to relapse, the question of tuberculous adenitis has been raised. But I have made a point of comparing notes with a large number of practitioners, from which I derive the impression, amounting to a practical certainty, that we have had in the towns of this district not inconsiderable epidemics of the disease. I hope very much that some of those who have had this experience will send a brief note to the JOURNAL, for only in this way can we get a really complete view of the disease. General practitioners are as a rule too busy to make many contributions to medical literature (to our great loss), but I shall be very much surprised if many do not confirm what I have stated, and say that an "unusual epidemic of sore throat with tedious and considerable glandular enlargement" has been a recent feature of their practice.

I am personally satisfied that the disease is one *sui generis*, and, in typical cases, presents no difficulty in diagnosis. I should be inclined to emphasize the frequency of some complaint of "sore throat," referred either to tonsils or pharynx, but in which the local changes, as revealed by inspection, are slight. The proportional affection of adults is also another interesting point.—I am, etc.,

Leeds, March 23th.

W. H. MAXWELL TELLING.

SIR,—I was very interested to read in the JOURNAL of March 26th the article on glandular fever by Drs. Tidy and Morley. The authors state that there is some reason to believe that a considerable number of cases are occurring at the present time, so it may be of interest to state that recently (from mid-February to mid-March) I have seen in this district nine cases of this nature. All of these patients were between the ages of 4 and 13 years; seven were in separate houses (most of them were isolated at once), and the remaining two were in the same house, one of these occurring six days after the first. I heard later that the mother in this house was ill nine days after the commencement of the first child's illness, and was in bed for two days with feverishness and swellings behind her ears. Seven of the cases were mild and the remaining two severe; one of the latter was complicated by nephritis, and there was definite oedema of ankles (Drs. Tidy and Morley state that there is no previous record of the occurrence of oedema). In this case all signs of nephritis had disappeared twenty-five days after the onset of the disease. The glands affected were the cervical beneath the sternomastoid muscles, and I found no other glandular enlargement. In eight of the nine cases the enlargement was bilateral; the glandular swelling was generally rather larger than a walnut, and there was comparatively slight tenderness. In every case the throat appeared normal. In one case a slight macular eruption appeared on the trunk on the sixth day; it caused some irritation and lasted two days. The temperature in no case exceeded 103° F.—I am, etc.,

Trunbridge Wells, March 25th.

R. D. AYLWARD, M.R.C.S.

X-RAY RADIATIONS AND CANCER.

SIR,—X-rays and radium are undoubtedly powerful therapeutic agents, but at present we fail to make full use of them, owing to the fact that we are as yet not masters of the technique necessary to get their full beneficial effect. Consequently most of our failures may be said to be due not so much to the fault of the agent as to the fault of the technique.

Our results are bound to be erratic until we know what are the conditions and dose necessary to produce a lethal effect on pathological cells, and at present they are to a great extent dependent on luck—that is, whether the particular dose administered happens to be the most effective one; and, secondly, on the practical experience of the radiologist himself. It ought to be possible not only to administer x-ray radiations with the same degree of accuracy as drugs, but to have some idea as to what prescription is required for the case in hand.

Dr. Reginald Morton has recently described a Continental method for deep therapy, and I have lately heard of yet another. Many of us can recall similar reports which before the war periodically found their way to this country from the same source, each in turn giving way to some newer idea. Consequently radiologists have become cautious about accepting without careful investigations these methods of "mushroom" growth. We must know on what foundation they are based—for instance, there is nothing to be gained by inventing ingenious apparatus for the production of large quantities of very penetrating rays unless we have some sound reason for thinking that this is the type of ray required.

Radiologists are divided into two schools—one striving for full cell absorption and the other for extreme penetration. The second class are endeavouring to obtain x rays as penetrating as radium, but I have yet to be persuaded that radium is of a greater therapeutic value than x rays properly applied, except, of course, in inaccessible positions; and I suggest the possibility that the therapeutic effect of radium may be due to something besides penetration. If we set out to produce skin reaction we use a medium or low type of ray without a filter, as this gives the greatest skin absorption in the shortest time. It is possible to get the reaction, however, even if we use a high-penetrating type of ray through a thick filter, but the exposure will be unnecessarily prolonged and nothing will be gained.

The same argument may be logically applied to deep-seated tissues—that to get our effect full cell absorption is necessary, and that by over-filtration we probably cut out the very rays that would have been absorbed by the pathological cells, and although to a certain extent this can be made up by prolonged exposure, the net result is the same. Until physicists alter their dictum that "x rays have no effect upon the medium unless absorbed by the medium," and this is backed up by the effect on the skin, it is wiser, I think, to work on the cell-absorption basis.

A large percentage of the cases of mammary carcinoma that pass through the x-ray department of the London Hospital die from metastases in the thorax or elsewhere in the body, while subcutaneous recurrences are controlled.

I have devised the duplex method of treatment installed in temporary quarters at the London Hospital with the idea of controlling general metastases in the same way as the more superficial. Any method devised for this purpose must fulfil two conditions: (1) It must be possible to administer a lethal dose to the pathological cells lying at various depths and in unknown positions; (2) the radiated area must be large.

The duplex method consists of two separate installations—one operating a tube in front and the other a tube at the back of the patient, both running at the same time. After the first full dose has been given, the direction is changed so that the radiation is now from side to side, the arms being forward and raised. In this way the deepest parts of the body are subjected to radiations from four points of the compass, and the resulting cell absorption must be much greater than with our present method. A large radiation field is used, including practically the whole trunk, this being attained by using the standard lead glass shield reversed. The duplex method, therefore, may be described as an elaborated method of cross-firing, differing, however, in two essentials from our present idea: (1) Both tubes are working at the same time from both sides of the body; (2) a very large area is covered.

These are the bare outlines of the method, which may be of value to those working on the absorption basis. From the statements made by some writers on the harmful effects of large doses of x rays, one may expect certain phenomena which are at present being watched for, but I feel certain that these can be avoided as long as the treatment is kept within certain limits, for I believe it is possible to give an overdose to the deeper structures in the same way as we can to the skin.—I am, etc.,

London, W., March 22nd,

S. GILBERT SCOTT.

Sir,—If, in my letter published a fortnight ago, I gave the impression that my technique in pre- and post-operative x ray treatment was originally based upon the results of animal experiments, I did not intend to do so. The method rests upon the clinical experience of ten years—an experience, I hasten to admit, more largely concerned with breast cancer than with any other, although I have also treated a considerable number of cases of malignant disease of the uterus. What I meant to imply was that the experiments at the Rockefeller Institute, and those made by Professor Russ in this country, furnished an explanation for the success of a dosage which is certainly insufficient to "kill" a growth by direct action upon the cells.

I have been familiar with the laboratory results referred to only for about three years, and I have not in any way altered my technique because of them. They are, however, of great interest to me as tending to confirm views which I had formed as a result of clinical observation. But it is not too much to hope that in the future the laboratory may enable us, by repeated examination of the blood, to graduate our x -ray dosage according to the response on the part of the patient.

Dr. Finzi says he has seen a few cases in which small doses apparently stimulated a growth; I have seen a few cases in which very large doses apparently produced a catastrophe—that is, there was a *post hoc* relation.

I have been careful not to apply opprobrious terms to the Erlangen method, for I have found it a good rule to believe that whenever an earnest and intelligent body of men consistently advocate a particular method, there is something, and usually a good deal, in it. I have also learnt not to condemn a drug or therapeutic procedure solely because the theory on which its use was based, or by which its action has been customarily explained, is eventually shown to be false. I commend these rules to Dr. Finzi.

With regard to British apparatus, the 24 in. coil has been long available, and I have myself, as an experiment, run x -ray tubes in an oil bath up to a 16 in. equivalent gap.

As is very often the case in controversies, the two schools are not nearly so far apart as might at first sight appear. Thanks in no small degree to the pioneer work of Dr. Finzi ten years and more ago, every one admits now that a tube with an equivalent spark gap of between 10 and 12 inches is desirable. Owing to lack of standardization of spark gap terminals, exact comparison is not easy. A 16-inch gap may be even better, but this does not necessarily follow, any more than it follows that increasing frequency of sound vibrations will indefinitely cause greater shrillness of note; a point comes when the effect on the ear begins to diminish. It may even be, as Knox has suggested, that each particular tumour has its own "note."

Then, as to dosage, we are all agreed that x rays must not be administered consecutively for long periods. When two or three large doses are given, the total period occupied may be nearly as long as when twelve or fifteen smaller doses are administered. The difference is thus narrowed down until it is, in practice, chiefly a question as to how to divide up a certain total of x -ray energy. About two years ago Professor Russ recorded a case of multiple carcinomata of the skin in which some of the nodules were subjected to single large doses; others to the same dose in fractions spread over several days. In each case the nodules disappeared, but in the former case with much, at any rate temporary, injury to the skin; in the latter with no such disturbance. Now, on the face of it, the divided dose seems the better here, but only a study of results over many years can in reality settle such a question. If, however, in the above instance, one had decided to cut out

the nodules surgically, I think there can be no doubt as to the advantage of the divided dose for pre- and post-operative treatment.

One has to remember that when a patient is operated on for cancer he has a surgical risk to face; and he may be cured whether any x -ray treatment is given or not. The big dose method is admittedly dangerous. If it is used as an alternative to surgery its risks may legitimately be faced; but why should we submit to fresh dangers a patient who has successfully come through an operation? Only the most positive proof that the divided dose is useless as well as harmless could lead us to abandon it, whereas a vast body of clinical and experimental evidence points to its value.

With theoretical considerations we need not concern ourselves overmuch. The advocates of the divided dose have never denied the value of x rays as destructive agents in localized cancer masses; but they claim that, even locally, the response of surrounding healthy tissues has as much to do with a good result as direct depression of malignant cells. That an excessive local dose may render the patient an easy victim to distant metastasis is now only too certain, but this danger has been recognized only comparatively recently, together with the fact that, by suitable dosage, the body resistance may be improved. The interaction of constitutional and local factors is so complex that it is doubtful if any conceivable technique can secure, coincidentally, the maximum help from each. In practice we shall obviously stress the one or the other, according as we have our attention specially directed to the main growth or to possible metastases.

Mr. Cecil Rowntree's reference to x -ray cancer in man needs a word of comment. Such cancer was produced by years of daily exposure to unfiltered rays, generally very soft. This is a very different matter from the use of hard filtered rays in courses which never extend over two months at a time, and are not repeated until an interval of three to six months has elapsed.

Mr. Child is against delaying operation for a single day; but this is surely an *ipse dixit* on his part—a thing which he deprecates in the radiologist. Whatever differences as to details may split the x -ray camp, he will find it now universally agreed that pre-operative radiation is desirable. The reason is obvious. The surgeon cannot guarantee that no cancer cells will be disseminated by the knife. If, therefore, any method is known by which either the cells of the primary mass can be made less active, or the tissues as a whole more resistant, or (better still) both of these desirable ends be accomplished, surely it should be used.—I am, etc.,

London, W., March 18th.

F. HERNAMAN-JOHNSON.

TUBERCULOSIS MORTALITY.

Sir,—We are still very much in the dark about the relation of health and disease to wages and prices; but all who value impartial inquiry, honest interpretation, and clear statement are in the debt of the author of the chart published by the *Times* on January 1st, 1921. Thanks to him, the main outline of the facts can be bought for a few pence. The information given in the chart that is relative to the problem set by variations in the rate of mortality from tuberculosis may be summarized thus:

1. From about 1857 to 1900 real wages in this country nearly exactly doubled. Total incomes from profit of various kinds increased during that period nearly as far and as fast. The rise in wages was due in part to nominal additions to their rate, but a nearly steady fall in prices kept raising real wages faster than nominal wages. That fall in prices stopped in 1875, but rises in nominal wages rather more than kept step with the rise in prices from 1895 to 1900. During that period (1857-1895) mortality from tuberculosis diminished, as we all know, steadily and rapidly.

2. From 1900 to 1914 nominal wages kept rising, but prices rose faster. Real wages accordingly fell and were, by 1914, about 10 per cent. under 1900. As we all know, the mortality from tuberculosis diminished more slowly during that period than while real wages were rising.

3. During the first three years of war prices rose far faster than wages, so that in 1917 the average wage-earner was no better off than in 1870. During that period the mortality from tuberculosis at first tended to rise, and then actually rose.

4. From 1917 to 1920 nominal wages rose faster than prices until, in mid-1920, real wages had risen nearly to the level of 1900. They were then, in fact, exactly as high, when measured in terms of commodities, as they had been in the years 1895-7-8. And, as we know, tuberculosis mortality is falling once more.

These facts come from an impartial source and are no doubt accurate. But we sorely need a fuller and more detailed statement. Will not Dr. Brownlee give us data, published in the *JOURNAL*, to show us what relation, if any, exists between consumption of food and consumption of alcohol in the country and mortality from tuberculosis? Is it possible to work out the average consumption of fats during the critical years?

Such data would be of the greatest value in other connexions. If, as the figures quoted above suggest, the wage earners as a class have been worse off during the past ten years than a generation ago, it is surely both unjust and unwise to encourage them to contribute largely to hospitals. During the period 1900-20 incomes from profits rose steadily irrespective of movements of prices. Profits and wages, which kept step while prices were falling, parted company so soon as prices began to rise. Both doubled in the earlier period. Profits alone increased in the later period. Surely it is to their owners rather than to wage earners that those who support the voluntary principle for the upkeep of hospitals should look for what larger expenditure the rise in prices has rendered necessary.—I am, etc.,

Brailford, near Derby, March 21st.

NORMAN LEYS.

IRRITABLE BLADDER.

SIR,—I have read with interest Dr. Hamilton's letter in your issue of March 26th on this subject. Such cases very frequently present themselves for treatment in Bath, and are cleared up by a course of drinking the mineral water.

If he will have a quantitative analysis made he will find that in all cases there is an abnormal amount of uric acid in the urine, and that frequently the specific gravity is low. I have come to regard such cases as due to the irritation caused by the excess of uric acid in crystalline form.

Speaking from twenty years' specializing in spa practice in Bath, I agree with him that both sexes suffer equally. I find in the urine of such patients anywhere from 0.5 to 1 grain per ounce of uric acid, and when cure has resulted the uric acid and the specific gravity have gone back to the normal. Sharp attacks of hæmorrhage have also not infrequently been reported in the histories.—I am, etc.,

Bath, March 27th.

CHAS. BEGG, M.B., C.M.EDIN.

ASTHMA AND ANAPHYLAXIS.

SIR,—Mr. Frank Coke's important and interesting paper on asthma and anaphylaxis suggests new lines of thought in this direction.

For some years the relationship of asthma to tuberculosis has interested me, and I had concluded on clinical grounds that tuberculosis may be in some cases the cause and in others the effect of asthma. In other words, asthma may predispose to tuberculosis by causing a local lowering of resistance; or, on the other hand, the onset of pulmonary tuberculosis may give rise to asthma in patients with an asthmatic diathesis.

This might account for some of the 50 per cent. of cases which he finds do not react to other proteins. Conceivably the exciting agent in the tubercle bacillus may be some portion of it other than tuberculin. No doubt Mr. Coke could devise a means of testing this.—I am, etc.,

Paignton, Devon, March 23rd.

E. WARD.

SIR,—In the interesting account given by Mr. Frank Coke, F.R.C.S., in the *BRITISH MEDICAL JOURNAL* of March 12th, a very vivid and striking picture is given of anaphylaxis.

I have used serums in the same persons in such a way that I think anaphylaxis might have occurred, and yet nothing but good has happened. And I venture to ask if anaphylaxis has ever been known to occur when serums are given by the mouth.

All the records of anaphylaxis seem to have followed the injection of serums; and if it could be proved experimentally that serum when given by the mouth implies immunity from the tragic syndrome of anaphylaxis, it would be a boon of the highest order.

Personally, I have never injected a case of diphtheria, but always for thirty years have given the antidote by the mouth, and its strikingly beneficial results, without any

of the drawbacks of injection, have been very gratifying. From 2,000 to 6,000 units can easily be given in a little chloroform water. And if this method confers immunity from anaphylaxis, it should, I think, be universally adopted in preference to injection.—I am, etc.,

Newcastle-upon-Tyne, March 20th.

T. M. ALLISON, M.D.

SAPRAEMIC GLYCOSURIA.

SIR,—It has been known for many years that reducing substances are apt to appear in the urine in toxic conditions and various infectious diseases. As far back as 1878 Prevost, in a treatise on intermittent glycosuria, laid particular stress on its association with suppuration, and subsequently Redard and others have emphasized the connexion. In none of the cases so far published, however, has the exact nature of the reducing substance been established, and unfortunately this point has also been overlooked by recent contributors to your columns.

My own experience has been that glycuronic acid, pseudo-laevulose, and more rarely true laevulose and pentose, either alone or with dextrose, occur more commonly in toxic conditions than pure dextrosuria. When the latter has been met with, examinations of the blood after a test meal have shown that the patient's carbohydrate tolerance was lowered, and that, although some improvement might take place under treatment, complete recovery did not occur. It seems probable, therefore, that there are two conditions, one a "pseudo-glycosuria," from which the patient completely recovers; and the other a true, or mixed, glycosuria, which improves when the source of the toxæmia is removed, but leaves the patient at least a potential diabetic.

Whether the lowered carbohydrate tolerance in the latter is antecedent to, and a predisposing cause of, the infection, or is entirely an after-effect, is a matter of opinion, but personally I am inclined to think it is the primary condition in all cases where dextrose is excreted. My chief reason for saying so is that I have never yet met with a case of furunculosis where the blood sugar was not abnormally high, in spite of the fact that in some there was no sugar in the urine and glycosuria never developed. A short time ago, for example, I saw a patient in consultation who had a large boil on his back and had been operated on for another on the buttock a few weeks previously. Although his urine gave no reaction for sugar, examination of his blood showed 0.24 per cent. three hours after a test meal, compared with 0.16 per cent. to 0.17 per cent. in a normal person.

With regard to the disappearance of sugar from the urine after the removal of a septic focus, it must be borne in mind that, just as a high blood sugar does not necessarily result in glycosuria, so the disappearance of sugar from the urine may be due to other causes than improved carbohydrate metabolism. The pseudo-glycosurias are no doubt part of a protective mechanism, and probably arise from defects in the functions of the liver consequent on the toxæmia, so that one would expect them to clear up when the source of the toxin is removed. A true dextrosuria is a different matter, and although some improvement in tolerance may take place so that sugar is only present in the urine intermittently, and when carefully looked for by delicate tests, complete cure does not occur, and examination of the blood will often show a high sugar content.

This week I have seen a patient whose urine was examined in the first instance owing to repeated attacks of boils; it was then found to contain a large amount of sugar. Under treatment the sugar disappeared, and when I saw him he was stated to be sugar-free. Examination of his blood showed 0.30 per cent. of sugar, however, and he had another boil forming on the back of his neck.—I am, etc.,

London, W., March 25th.

P. J. CAMIDGE.

THE DENTISTS BILL.

SIR,—Mr. Campbell's letter, published in your issue of March 12th, p. 408, is so entirely inaccurate and misleading that it must not be allowed to pass unchallenged. Mr. Campbell states that the Dentists Act of 1878 prohibited unqualified dental practice, and that the Dentists Bill of 1920 does not. Exactly the opposite is the case.

The 1878 Act prohibited title only, and it was precisely because this course completely failed to safeguard the public that the 1920 bill was introduced, containing, as its essential feature, the strictest prohibition of unregistered practice in all its forms. As a corollary to this, in consideration of the vested interest of the present unregistered practitioners, it proposes to admit to the *Register*, under the control of the General Medical Council, all those who have been in bona fide practice for five years and are of good character. To this the British Dental Association, and the dental profession generally, strongly object, and they will use every endeavour to obtain a provision whereby the great majority of such practitioners shall not be placed on the *Register*, but upon a roll, under the control of the General Medical Council, entitling them to continue in practice, with the privilege of full registration on passing an examination of a practical character within a specified time.

Again, Mr. Campbell says, "A very glaring omission from the bill is a clause constituting a tribunal to investigate all claims for admission to the *Register*." But, Sir, Clause 2 is wholly concerned with the constitution of a board for this very purpose, and generally for the regulation of the dental profession, a board under the General Medical Council consisting of representatives of the Privy Council, the General Medical Council, the Ministry of Health, and the dental profession in Great Britain and Ireland. Surely he cannot have read the bill he is criticizing so severely!

The retention of company practice may be regretted, though it is really of little importance, as the main object of dental company practice—namely, the evasion of the law—is defeated by the provision that all the directors, managers, and operating staff must be registered dentists, and, as such, amenable individually to the jurisdiction of the General Medical Council, an exception being made in the case of directors and managers, not operators, who have acted in this capacity for a period of five years before the passing of the Act. Having no longer a reason for existence, dental companies will probably soon die out. The bill, on the whole, is a good bill. With the modifications suggested above and some others of a minor nature, it will have the support of the General Medical Council and the British Dental Association, and, if it becomes law, will be of the greatest benefit to the health of the nation and the advancement of dentistry.—I am, etc.,

London, W., March 18th.

J. H. BADCOCK.

COMMITTEE FOR THE PREVENTION OF TROPICAL DISEASES:

SIR,—In your issue of March 12th you report, under the heading, "The Future of Research in Tropical Medicine," Sir Leonard Rogers's presidential address delivered before the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on February 24th last. In this report he is quoted as saying:

"A few months ago I received an invitation to join an influential Committee for the Prevention of Tropical Diseases, but on learning from their circular that they proposed to spend £30,000 on a single expedition to a very small and rather healthy (because malaria-free) West Indian island, I felt obliged to decline the invitation, as I could not agree with such a policy. . . ."

Now, there is nothing in the circular in question which would lead anyone who reads it with ordinary attention to suppose that the policy of the committee is as stated by Sir Leonard Rogers, and it is not now, nor has it ever been, the policy of the committee to spend £30,000 "on a single expedition to a small and rather healthy . . . West Indian island." On the contrary, to quote the words of the circular, "the committee . . . proposes to begin operations by carrying out a thorough medical survey of the Lesser Antilles," and "it is expected that the survey of this group of islands will take about three years . . ."

Sir Leonard Rogers has not only misstated the objects and policy of the committee, but, not having attended any of the committee's meetings—at which his presence would have been most welcome—he has not, in fact, any accurate knowledge of what is in the minds of the members of the committee on this subject, and he has publicly criticized and stated his objection to a policy which has never been in contemplation by those concerned.

In the course of his speech Sir Leonard Rogers went on to refer to the benefits to be derived by the establishment of laboratories in various British tropical possessions, and many discussions have taken place as to what may ultimately be done in this respect. With this we are *ad idem* with him, but it is the view of the committee that (except as regards the travelling laboratories which necessarily accompany every expedition) the expedition should precede the permanent laboratory, and that this opinion has been justified in the past—as for example by the remarkable successes of the expeditions which have investigated malaria, plague, sleeping sickness, and other tropical diseases. The knowledge gained by these expeditions has been worked out at a later stage in permanent laboratories, which are in themselves, when suitably located, necessary, if expensive, institutions. That this policy has found favour in other quarters is evidenced by the previous missions (followed, it may be, by permanent laboratories) which have been sent out by the Rockefeller Foundation, as well as that now commissioned by the London School of Tropical Medicine, to carry out part of the identical West Indian scheme adumbrated by this committee and which Sir Leonard Rogers appears to condemn.

These pamphlets were sent to members of the medical profession and others likely to be interested. They were marked "Proof." It was evident, therefore, that they were not yet intended for public circulation, nor, one would have thought, were they fair matter for public criticism.—I am, etc.,

E. T. JENSEN,

Honorary Secretary, The Tropical Diseases
Prevention Committee.

London, W.1, March 23rd.

CONSULTANTS' LETTERS.

SIR,—It has unfortunately become the custom of certain medical practitioners, when one of their patients has visited a consultant, to give to the patient the letter received from the consultant respecting diagnosis, prognosis, and treatment. In recent years, when a patient has consulted me a second time, I have not infrequently been surprised by his presenting me with the letter I had written to his medical attendant after the first consultation. On inquiry, I have generally found, in such cases, that my letter had been given to the patient soon after the first consultation, and, of course, carefully read by him. No doubt patients often desire to read consultants' letters, but only a minority of practitioners would give such letters to the patients.

Whatever views may be held, it is clear that if this custom increases it will be desirable that consultants in their letters to practitioners should avoid giving their diagnosis in the case of certain diseases, and avoid expressing any prognosis unless favourable. In writing such letters I try to bear in mind that the letter may possibly be read by the patient, and therefore omit much I should otherwise have said. I think it is desirable that attention should be drawn to this subject, as in the past most consultants have been in the habit of freely expressing their opinion as to diagnosis and prognosis in their letters to practitioners, and have not expected that such letters would be given to the patients.—I am, etc.,

March 18th.

PHYSICIAN.

THE LATE DR. NEWTON OF STOKE-ON-TRENT.

SIR,—Dr. Francis Morley Newton, medical officer of the Stoke-on-Trent Union Hospital, died on February 15th, 1920, leaving a widow and four children (aged, 8, 7, 6, and 1½ years). Dr. Newton was educated at Epsom and St. Bartholomew's. He suffered from asthma and diabetes and was unable to insure his life or to make provision in any other way for his family, so that their present financial position and future prospects are precarious.

A fund in aid of the widow and children has been opened under a committee having for chairman Mr. R. H. Dickson, F.R.C.S.I., Newcastle-under-Lyme (Chairman of the North Staffordshire Division of the British Medical Association, and President of the North Staffordshire Medical Society), and Mr. W. Webster, Newcastle-under-Lyme, as Secretary. The committee feels that friends or fellow-students of the late Dr. Newton might wish to contribute to the fund, and

takes the opportunity of the publicity offered by your columns to reach them. Contributions will be gratefully received and acknowledged by the Chairman or Secretary.—I am, etc.,

WM. WEBSTER,
Secretary to the Fund.
64, King Street, Newcastle, Staffordshire, March 28th.

Obituary.

LAWRENCE DREW SHAW, D.S.O., M.B., CH.B.GLAS.,
Pathologist to the London Lock Hospital.

We regret to record the sudden death, in London on March 17th, of Dr. Lawrence Drew Shaw, D.S.O., late temporary Lieutenant-Colonel R.A.M.C., who served with great distinction in the war. He was born in 1881 and passed from the Dollar Academy to the University of Glasgow, where he graduated M.B. and Ch.B. in 1904. As a medical student he served in the South African war of 1899-1902, receiving the Queen's Medal. After qualifying he went to the Far East and settled in practice at Tientsin. On the outbreak of hostilities in 1914 he served against the Germans in North China, taking part in the siege and capture of the German fortress of Kiauchau. He then returned to Europe and took a temporary commission as lieutenant in the R.A.M.C. on March 15th, 1915, becoming captain a year later. After serving in Gallipoli he went to France in 1916, and was promoted acting lieutenant-colonel on January 29th, 1917. Colonel Shaw was awarded the D.S.O. on June 4th of that year, and fourteen months later he received a bar to the D.S.O. The official record of the second award ran as follows:

"He was placed in charge of the forward division of the combined field ambulances. Although constantly exposed to heavy shell and machine-gun fire, he organized the system of evacuation and extended it to neighbouring divisional units. By his inspiring example and disregard of danger he ensured a complete and successful evacuation of the wounded."

In June, 1919, he received the French Croix de Guerre. After demobilization he came to London and had done good work as pathologist to the London Lock Hospital.

A colleague who served with him in a field ambulance on the Somme in 1916 writes: "Lawrence Drew Shaw was an exceedingly brave man of outstanding character and ability. The war gave him the opportunity to show his mettle, and he seized it with both hands. Fearless and high-spirited, of magnificent build and physique and abounding energy, he was a born leader of men. Those who made his acquaintance early in the war knew that if his life were spared he would win high honours for courage and leadership in the field. When things were going wrong Shaw's commanding presence would steady the position. He delighted in action, and inspired others to do better than their best. He had a sound working knowledge of his profession, which he put to good use amidst the difficulties and makeshifts of practice on active service. What particularly struck many of us was his instant grasp of the medical needs of a military situation. Just as in danger he cheered up his colleagues and his men, so in dull times he was the best of companions. The epithet 'lion-hearted' seemed to fit Lawrence Drew Shaw better than any man I ever knew."

DR. THOMAS FORT, who died at Oldham on March 13th in his 68th year, received his medical education at St. Thomas's Hospital and took the diplomas of L.R.C.P. and L.M.Edin. and M.R.C.S.Eng. in 1877. He was a native of Preston and went to Oldham as a young man, where he built up a large practice and became very popular among a large circle of friends. He held the posts of certifying factory surgeon and police surgeon for about forty years, and about fifteen years ago was appointed surgeon to the post office. For many years he was associated with the volunteer movement, receiving the Volunteer Decoration for twenty-three years' service before the formation of the Territorial Force. He retired on account of advancing years shortly before the outbreak of the recent war, with the rank of honorary surgeon-colonel. He was a member of the Oldham Division of the British Medical Association, and is survived by his widow, a daughter, and two sons, both of whom are members of the medical profession.

DR. JOHN DROUGHT KENNY, whose death occurred on March 9th at his residence, The Grange, Wickersley, near Rotherham, was a native of Ireland, and obtained his medical education at Queen's College, Galway, and at the Ledwich School and Adelaide Hospital, Dublin. In 1884 he graduated M.D., M.Ch., R.U.I., and L.M. Rotunda, and in 1887 went to Yorkshire, where, after an assistant-ship, he settled down in practice in the village of Treeton, remaining there for the next twenty-five years. He built up a large and busy practice, and gained the esteem and affection of all classes by his cheery good-nature and unsparing devotion to his work. The poor and needy ever found him a ready and generous friend, and it will long live in the memory of the villagers how he helped them with money and provisions during a long and serious coal strike. His patients and friends showed their appreciation by presenting him with a handsome motor car when he left them, in 1912, to take up practice in Wickersley. He held numerous appointments under the Guardians, the Yorkshire Coalowners' Indemnity Company and various colliery companies, and he also took much interest in ambulance work. He was a staunch and sincere churchman and rendered many valuable services to the Church of England. His death, which occurred from pneumonia after a few days' illness, came as a great shock to his many friends. He is survived by his widow, with whom much sympathy has been expressed.

DR. HARRY HOLLIS died on March 12th, aged 54, at Redenhall, Norfolk, where he had gone on retiring from practice at Wellingborough last summer. He was born in Derbyshire, and studied medicine at St. George's Hospital and the University of Cambridge. He graduated B.A. in 1890, M.B., B.Ch. in 1893, and M.D. in 1898. After holding house appointments at St. George's Hospital and the Derbyshire Hospital, he became house-surgeon to the Northampton General Hospital, and ultimately removed to Wellingborough, where he joined Dr. Audland in partnership. Dr. Hollis had been a member of the old school board, a governor of Wellingborough School, and was one of the founders of the local Children's Welfare Centre. He was never very robust in health, and two years ago had an illness which led to his retirement. As a mark of esteem in which he was held, the townspeople of Wellingborough raised £200 as a testimonial to Dr. Hollis's work in the district. Whilst in active practice he was a member of the Northamptonshire Division of the British Medical Association. He is survived by his widow, two daughters, and a son.

THE death took place, at a nursing home in Edinburgh, on March 12th of Dr. ALEXANDER VEITCH, a well-known medical practitioner of Edinburgh. Educated at Edinburgh University, where he graduated M.B., C.M. in 1890, he subsequently acquired a large general practice in the city. Latterly he acted as a medical referee in workmen's compensation cases, and his pronouncements in these made him widely known. Dr. Veitch had more than the usual general practitioner's skill in surgical operative work, and he had also an extensive panel practice, being one of the first practitioners to take service under the Insurance Act. Of a kindly and philanthropic disposition, a lover of nature and a student of literature, he was widely esteemed. He took a keen interest in motoring in the early days of the industry, and was one of the first to make use of a motor car in his professional work.

THE death is announced of Mr. DAVID MORGAN BEDDOE of Cairo. He was born in December, 1869, and received his medical education at Guy's Hospital. He took the diplomas of M.R.C.S., L.R.C.P.Lond. in 1893, and that of F.R.C.S.Eng. two years later. After serving as house-surgeon at Guy's Hospital and at the Newport Infirmary he went to Egypt for the benefit of his health and soon established a successful practice in Cairo, where he became surgeon to the Anglo-American Hospital. Mr. Beddoe's literary tastes were well known; he was the author of several works of fiction, and of *A War Surgeon at the Red Cross Hospital, Cairo*, describing some of his experiences during the war.

THE LATE DR. W. IRONSIDE BRUCE.

AN old friend and colleague sends an appreciation of Dr. Ironside Bruce, of whom an obituary notice appeared in our last issue: When many years ago the writer first met Ironside Bruce it was as his chief clinical assistant at Charing Cross Hospital. At that time the picture was that of a young man remarkable for his quickness of action and manner, with rapid and incisive speech, and with just a piquant flavour of Scotland on his tongue. Endowed with marvellous energy, he was wonderfully patient with others and kind and considerate to his subordinates. To his clinical assistants Bruce was invariably helpful, always at their back, yet urging them on to work out things for themselves, and this, not from any inclination to shirk work, but because he appreciated the fact that the only way to teach people was to let them find their own legs. The wealth of Bruce's knowledge in his own sphere of work was shown in the excellence of his lectures and demonstrations to men who were working for the diploma in medical radiology of Cambridge University. On the subject of the necessity for comprehensive teaching of the radiologists of the future, there was no greater enthusiast than Bruce; only a week ago the writer received a message from him that he hoped he might be able to give some lectures in the ensuing term. How far the strenuous work done by Ironside Bruce during the war helped to lower his vitality the writer can only surmise; he does, however, know that from the enormous x-ray department of the King George (Military) Hospital, with but short and infrequent rests, Bruce was never absent on one of his appointed days. To the writer Bruce has never appeared to have been quite the same man since that time of terrible stress. Ironside Bruce was a clever man, a man of shrewd judgement, and withal a man of the most winning personality. Had he been spared there is no knowing what valuable records he might have left behind him. The stress of busy practice left him no time to give to the world what he could have given, and what, as he told the writer, he hoped to give. That he died a martyr to the science he loved is a truism; that a life so full of great possibilities should have been sacrificed is nothing short of a calamity. It is for us to do what we can to lessen, if possible, this sacrifice of life among x-ray workers.

The following message from His Majesty has been received by the Earl of Lonsdale, Treasurer of Charing Cross Hospital: "The King has learnt with much regret of the tragic death of Dr. Ironside Bruce, radiologist to the Charing Cross Hospital, and I am commanded to convey to you and the hospital staff His Majesty's sincere sympathy in the loss of so brilliant a physician, who sacrificed his life in the cause of science and humanity."

The post-graduates attending the courses in radiology for the Cambridge diploma at the Fellowship of Medicine and Post-Graduate Medical Association adopted, on March 23rd, a resolution expressing their sympathy with the widow, and putting on record their admiration of Dr. Ironside Bruce, "whose genial good-nature, ability as a teacher, and self-sacrificing devotion to his work endeared him to all with whom he came in contact."

The death is announced of Mr. C. A. NANJAPA, I.M.S. Colonel J. Smyth, I.M.S., retired, formerly senior surgeon and sanitary commissioner, Mysore, writes:

C. A. Nanjapa, I.M.S., M.R.C.S., L.R.C.P., senior surgeon to the government of His Highness the Maharaja of Mysore, passed away on February 19th, 1921. He had just been promoted to the highest position in His Highness's medical service, yet a young man full of zeal and energy and high determination in regard to the duties that now devolved upon him. He spent a week with us here last year. He was obviously then much out of health, and was full of appreciation of the kindness of the profession in London to him in connexion with his disability. The loss of his only son and child on the way to England was a severe blow to both parents. And now the end has come. Of a very bright optimistic disposition, yet never anxious to appear much in public, he seldom published his work. It sufficed for him that he did his work conscientiously and well. In the hospital his cheery hearty manner contributed much to the contentment and comfort of the patients. He did not grow rich; to have a competence sufficed him. A gentleman in all respects, he left good impressions wherever he went. Educated in Madras, London and New York, and specializing in electro-therapeutics, his knowledge of men was as wide as his knowledge of medicine. He was absolutely free from suspicion or mistrust in Englishmen. He gave us credit for entire sincerity and a desire to be true to our salt. He was therefore a personal friend of many Englishmen, whose hearts were won by the straightforward manly spirit he always evinced.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Diploma of Psychological Medicine.

A FIVE weeks' revision course for the Diploma examination will be held in Cambridge from July 18th to August 20th. The course will include lectures and laboratory work on the Anatomy and Physiology of the Central Nervous System (Dr. Thacker) and on Psychology (Dr. Lowson) for Part I of the examination, and lectures and clinical work on Psychopathology (Dr. Myers and Dr. Prideaux) and on Mental Diseases (Dr. Archdale) for Part II.

The fee for the whole course is 12 guineas. That for the course for Part I or Part II alone is 6 guineas. The examination for Part I (Anatomy and Physiology of the Nervous System, and Psychology) is held in October and that for Part II (Neurology and Psychiatry) in December. Further information may be obtained from the Secretary to the D.P.M. Committee, Psychological Laboratory, Downing Street, Cambridge.

UNIVERSITY OF DURHAM.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.S. (Materia Medica, Pharmacology and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology).—J. N. Alexander, Florence Bentham, R. W. Locke, G. C. E. Refell, C. A. Wilson, Eleanor H. Wylam, Ella L. Young.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

M.D.—Amy Hodgson, N. W. Walmsley.
FINAL M.B., CH.B.—Class II. *J. G. L. Jones. Part III. Ellen Dowling, F. H. Edwards, S. Farris, W. S. Gilmour, H. T. Hughes, R. M. Jones, Florence M. Lampert, R. F. J. Martin, F. G. Pallthorpe, J. H. Pottinger, A. McK. Reid, J. C. Twomey. Part II. G. C. Bhatia, Eleanor E. Briant, H. R. Chibber, C. Cookson, Part I. Ethel Ashton, H. R. Chibber, G. Clark, H. M. Cohen, R. W. Cowie, J. Elsohn, I. S. Fox, H. S. Gordon, R. C. Gubbins, W. D. Jeans, T. Knowles, Mary E. Nosworthy, G. Sanders, S. G. Sheir, Mary D. H. Sheridan, W. T. de V. Thomson, Mary G. T. Williams, D. A. Woodeson.

D.P.H.—A. J. Hawes, J. O. Murray, L. B. Stott.
D.T.M.—R. Nixon, A. S. Richmond, J. M. Skinner, R. B. Stewart, Marion Thomson.

D.M.B. AND E.—C. C. Anderson, J. H. Mather, R. E. Roberts, R. I. C. Rodgers.

* Honours in Obstetrics.

† Honours in Forensic Medicine and Toxicology.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

THIRD M.B. AND CH.B. (General Pathology and Morbid Anatomy).—Elsie C. Begg, L. Boyars, F. W. W. Fox, E. S. Frischmann, R. Handley, Mary Kent, C. B. Kirkbride, G. A. Lord, Greta Lowe, G. L. Meachim, A. A. Pomfret, Eleanor P. Smith, J. H. Struthers, C. B. V. Walker.
D.P.H.—Marion Draper, J. H. Sheldon.

UNIVERSITY OF EDINBURGH.

AT the graduation ceremonial held in the McEwan Hall on March 24th the degrees of M.B., CH.B., were conferred in absentia upon Bernard Friedman.

UNIVERSITY OF ABERDEEN.

THE following have passed the final professional examination in medicine:

C. D. Allan, J. J. H. Anderson, N. C. Bodenstein, C. K. Chen, *J. Craig, Lillian F. Gall, R. K. Grant, G. W. Hay, *Eleanor M. P. Law, Margaret Lipp, *D. G. MacDonald, A. MacKay, Elsie Mackie, Katherine C. Van de Merwe, Mary G. Milne, Dorothy Mitchell, John I. Moir, Marion E. Mowat, J. M. H. Murray, *Janet C. Nicol, *Mary M. Pyper, A. E. Reid, E. N. D. Repper, *J. P. G. Rossouw, G. Saint, N. C. Simpson, G. V. G. Smith, I. R. Stark, *A. L. G. Thomson Butterworth, I. S. Thomson, A. B. Wood.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary Comitia of the Royal College of Physicians of London was held on Monday, March 21st, at 5 p.m., with the President, Sir Norman Moore, Bt., in the chair.

The annual address was delivered by the President, who referred eloquently to the seven Fellows who had died during the past year—Dr. M. Handfield Jones, Dr. Philip John Hensley, Dr. David Lloyd Roberts, Dr. William Murray, Sir Frederick Taylor, Dr. William Odling, and Sir Felix Semmon.

The Comitia then proceeded to the election of the President, and Sir Norman Moore was re-elected. Licence to practise was granted to Evelyn Francis Pebbington, of Liverpool University. The President then dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. APPROACHING ELECTION OF COUNCIL.

FOUR vacancies on the Council of the Royal College of Surgeons will be filled on Thursday, July 7th. The outgoing members are Sir George Makins and Mr. Ernest Lane, who do not seek re-election, and Mr. Waring and Mr. Burghard, who are coming forward again.

The constitution of the Council at present is as follows:

President.—Sir Anthony Bowlby, K.C.B., K.C.M.G., K.C.V.O., C. (1) 1904, (2) 1912, (3) 1920. Pres. 1920.
Vice-Presidents.—Sir Charles A. Ballance, K.C.M.G., C.B., M.V.O., C. (1) 1910, (2) 1914. Sir John Bland-Sutton, C. (1) 1910, (2) 1918.

Other Members of Council.—Sir George H. Makins, G.C.M.G., C.B., C. (1) 1903, (2) 1911, Pres. 1917; Sir Charters J. Symonds, K.B.E., C.B., C. (1) 1907, (2) 1915; Mr. W. F. Haslam, C. (1) 1903, (2) 1916; Sir D'Arcy Power, K.B.E., C. (1) 1912, (2) 1920; Sir Berkeley G. A. Moynihan, K.C.M.G., C.B., C. (1) 1912 (substitute), (2) 1919; Mr. James Ernest Lane, C. 1913; Mr. H. J. Waring, C. 1913; Sir William Thorburn, K.B.E., C.B., C. 1914; Mr. W. McAdam Eccles, C. 1914; Sir Charles Ryall, C.B.E., C. (1) 1914 (substitute), (2) 1915; Mr. Walter G. Spencer, O.B.E., C. (1) 1915 (substitute), (2) 1918; Mr. F. F. Burghard, C.B., C. 1915 (as substitute till 1921); Sir Herbert F. Waterhouse, C. 1915; Mr. T. H. Openshaw, C.B., C.M.G., C. 1916; Mr. Raymond Johnson, O.B.E., C. 1915; Mr. V. Warren Low, C.B., C. (1) 1916 (substitute), (2) 1917; Mr. J. Sherren, C.B.E., C. 1917; Sir John Lynn-Thomas, K.B.E., C.B., C.M.G., C. 1918 (substitute till 1925); Mr. Ernest W. Hey Groves, C. 1918; Sir Cuthbert S. Wallace, K.C.M.G., C.B., C. 1919; Mr. F. J. Steward, C. 1920.

The medical schools, etc., are represented as follows:

London:

St. Bartholomew's	4
Charing Cross	1
Guy's	2
King's College	1
London	2
Middlesex	1
St. Mary's	2
St. Thomas's	3
University College	1
Westminster	1
Special London Hospital	1

Total London... .. 19

Provincial:

Birmingham	1
Bristol	1
Cardiff	1
Leeds	1
Manchester	1

Total Provincial... .. 5

Total Council... .. 24

The Serbires.

ADDITIONAL PAY FOR OFFICERS ON COMMITTEES.

AN Army Order provides that a field officer on full pay who is appointed to serve on a committee, or to act as its secretary, in virtue of part of his pay for a subaltern serving in similar circumstances will have additional pay of 10s. a day.

R.N. MEDICAL CLUB DINNER.

THE annual dinner of the Royal Navy Medical Club will take place at the Hotel Cecil, London, on Thursday, April 14th, 1921, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the Honorary Secretary, Royal Navy Medical Club, 1, Lake Buildings, St. James's Park, S.W.1, not later than seven clear days before that date.

HONOURS.

FOREIGN DECORATIONS.

THE following are among the decorations and medals awarded by the Allied Powers for distinguished services rendered during the war 1914-19:

By the King of the Belgians.

Ordre de Léopold—Officer: Lieut.-Colonel John Kyffin, T.D., R.A.M.C.(T.F.). *Ordre de la Couronne*—Officer: Temporary (Honorary) Lieut.-Colonel Edward Stewart, R.A.M.C.; Colonel Sir John Hewat, Assistant Director of Medical Services, South African Defence Force.

By the President of the French Republic.

Médaille des Epidémies—en argent: Temporary Major (acting Lieut.-Colonel) George D. Gray, O.B.E., R.A.M.C.; en bronze: Temporary Captains Clement A. Hughes, Charles F. Strange, and Herbert Tomlin, R.A.M.C. *Palme Académique*—Officer: Captain William Adams Smith, C.A.M.C.

By the King of Italy.

Order of the Crown of Italy—Officer: Brevet Lieut.-Colonel Frederick S. Brereton, C.B.E., R.A.M.C. *Chevalier*: Captain Hugh Richard Phillips (late Surgeon R.N., and Captain R.A.M.C.).

Medical Delus.

AT a representative council meeting of the National Council for Combating Venereal Diseases, held on March 23rd, at the Royal Society of Medicine, Lord Gorell, President of the Council, made a full statement as to the relations now subsisting between the National Council and the Society for the Prevention of Venereal Disease. A memorandum (summarized in our last issue at p. 476) defining the policy of the National Council, which had been submitted to and received the approval of the Minister of Health, was considered in view of the report of the Special Committee of the National Birth Rate Commission. After discussion and the moving of an amendment, which was rejected by 41 votes to 8, the memorandum was adopted. Reports were received of the valuable work carried out under the aegis of the Colonial Office by the three Commissions of the National Council which visited Shanghai, Hong Kong, Singapore, Ceylon, Malta, Gibraltar, Jamaica; Barbados, Grenada, Trinidad, Demerara, and Bermuda.

THE King, with the advice of his Privy Council, has nominated Sir Francis Champneys, Bt., M.D., to be, for a further term of five years from May 23rd, 1921, a member of the General Medical Council.

A COURSE of twelve practical demonstrations, on the management and feeding of infants and young children, for medical practitioners will be given at the St. Mary-lebone General Dispensary, Welbeck Street, W.1, by Dr. Eric Pritchard, on Tuesdays and Thursdays, at 10.30 a.m. and 3 p.m. respectively, commencing on April 5th. The fee for the course is two guineas, and opportunities will be afforded to students of visiting on Saturday afternoons the Nursery Training School, 1, Wellgarth Road, Golder's Green, and seeing there the methods employed in dealing with infants.

AT the annual meeting of the Society for the Study of Inebriety, to be held at the rooms of the Medical Society of London, 11, Chandos Street, W., on Tuesday, April 12th, at 4 p.m., Dr. H. H. Dale, F.R.S., will open a discussion on the use of alcohol in medicine.

A SPECIAL post-graduate course will be held at the North-East London Post-graduate College from Monday, April 25th, to Saturday, May 7th, inclusive. At 10.30 a.m. and at 11.45 a.m. each day practical demonstrations will be given on clinical and laboratory methods applicable in medical practice. At 2 p.m. demonstrations will be given on groups of cases illustrating special subjects, and at 3 p.m. on selected cases in various departments of practice. At 4.30 p.m. there will be either a clinical lecture (by Sir William Hale-White, Sir Thomas Oliver, Sir Henry Gauvain, Mr. H. D. Gillies, Dr. P. Manson-Bahr, Dr. Frederic Thomson, and others), or clinical consultations on obscure medical and surgical cases. On Saturdays demonstrations will be given on the early diagnosis of the infectious fevers at the North-Eastern Fever Hospital, St. Ann's Road, London, N., and on cases of insanity associated with epilepsy at the L.C.C. Mental Hospital, New Southgate, London, N. Luncheon will be obtainable in the neighbourhood and tea will be provided each day at 4 p.m. The fee for the course is 3 guineas or 2 guineas for either week. The lectures at 4.30 p.m. will be free to qualified medical practitioners. Further information may be obtained from the Dean of the College at the Prince of Wales's General Hospital, Tottenham, N.15.

WE are asked to state that the meeting of the Section of Psychiatry of the Royal Society of Medicine arranged for April 12th will not be held.

DR. ARTHUR ALFONSE MILLER has received the Cross of Chevalier of the Legion of Honour conferred upon him by the President of the French Republic in recognition of his services to the French sick and wounded in the late war.

DR. ROBERT SHAND TURNER, who is leaving Keith, where he has practised for over fifty years, to reside in Edinburgh, has been presented by his friends and patients with a cheque of £360, and Mrs. Turner with an inscribed silver casket, as a mark of their esteem and regard.

DR. T. HENRY JONES, on the occasion of his retirement from the office of County M.O.H. for Surrey, has been presented by the members of the County Council and committees thereof with two Persian rugs and an illuminated address, and Mrs. Jones with a silver kettle and hot-water jug, as a mark of esteem.

THE annual general meeting of the London and Counties Medical Protection Society will be held at the offices of the Society, 32, Craven Street, Strand, W.C.2, on Wednesday, April 6th, at 4 p.m.

DR. F. E. WYNNE, on the occasion of his relinquishing the medical officership of health for the county borough of Wigan to become medical officer of health for Sheffield, has been presented by the various staffs of the Wigan Health Department with a silver tea service as a mark of appreciation and esteem.

THE second annual reunion of the Workers for Serbia will take the form of a dinner and dance to be held at the Wharfedale Rooms, Hotel Great Central, on Tuesday, April 19th, at 7 p.m. Colonel Sir Courtauld Thomson, K.B.E., Chief Commissioner of the British Red Cross for Malta and the Near East, 1915-1919, will be in the chair, and a large gathering of the medical men and women who served with the medical missions or with the R.A.M.C. units attached to the Royal Serbian Army is hoped for. Tickets, price one guinea each, may be obtained from the honorary secretary, Miss Marx, 24, Melcombe Court, Dorset Square, N.W.1.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South (telegrams: *Bacillus*, Dublin; telephone: the Scottish Office, 6, Rutland Square, Associate, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

TRUSS FITTING.

DR. J. J. E. BIGGS, O.B.E. (Cardiff) writes: Can any of your readers give me any information as to how to get a patient measured for a truss? The patient is a female, aged, feeble and emaciated, with an old-standing spinal curvature; there is a femoral and an indirect inguinal hernia in the right side. Most of the instrument makers I have tried have attempted to make the patient fit their pre-conceived notion of a truss instead of trying to make the truss fit the patient. It is impossible for the patient to travel to London for fitting. Before the war one firm, I remember, supplied me with a soft metal piece of wire, marked in inches, which could be firmly and accurately modelled on the patient and removed without altering the contour.

*(1) It is doubtful whether an aged, feeble, scoliotic patient with a hernia is a suitable case for any spring-truss. (2) When fitting at or by the maker is impossible, it is a good plan to make use of the soft metal graduated cyrtometer, listed in all surgical instrument catalogues. The cyrtometer can be folded and sent to the maker in a box, or its curvature, when fitted, can be traced on paper and so reach the truss-maker. (3) If the truss when received does not fit exactly, the medical man can generally do what the maker would do—bend the spring appropriately with his hands, perhaps with the aid of a vice or improvised equivalent. The resources of a "car" are nearly always adequate, for the "temper" of the spring is not as a rule very high. (4) When a spring-truss is unsuitable it is sometimes easy to attain the desired support by using a more or less triangular pad, held in place by webbing and elastic straps attached to the three corners, in the manner adopted by one of the well known patent "cures." (5) In the presence of emaciation it may be found most satisfactory to use a spica bandage of crêpe over an appropriate pad. (6) Makers certainly sometimes expect patients to be content with unsuccessful efforts, but when they do not see the patient they may fairly expect the doctor to do something towards fitting the truss after receipt.

INCOME TAX.

"S. H. S." inquires whether it is correct for the earnings of his partner and himself to be assessed in one sum, less the aggregate allowances for both.

* The assessment must be made in one sum on the profits of a partnership practice, but the local inspector will usually supply on request such supplementary particulars as are necessary to enable the net duty payable to be correctly apportioned between the partners. The abolition of this inconvenient system of assessment was urged by the British Medical Association representative before the Royal Commission on Income Tax, and the suggestion was favourably received.

"M.D. EDIN." bought a car in 1910 for £250, and sold it for that sum in 1920, buying a new one for £400. He asks if he can deduct the £350 as an expense.

* An official witness before the Royal Commission on Income Tax stated that, provided an improvement was not effected, the actual cost of the replacement of a machine would be allowed. Assuming that the new car is not of superior power or quality, "M.D. Edin." appears to be entitled to deduct the £350.

LETTERS, NOTES, ETC.

THE STETHOSCOPE IN FRANCE.

INASMUCH as the stethoscope is a French invention it is always something of a surprise to the British or American medical traveller in France to find that the binaural stethoscope is virtually unknown there, and the use of even the single wooden implement is restricted to investigation of difficult heart sounds. There are, of course, physicians in this country, especially of the old school, who use the wooden stethoscope, of the heart, but they are to defend their neglect of the binaural stethoscope on the ground that the respiratory and other sounds are changed and distorted by passage through the tubing. To this it may be replied that, although the sounds are indeed modified, so is the voice of a friend heard through the telephone; yet this fact does not prevent our recognizing his voice, detecting his emotions, and understanding his speech. Practice is needed to learn to distinguish sounds heard through the binaural instrument has certain positive advantages. Thus, it greatly facilitates examination, since one can "run over" the chest in a very short space of time; again, in hospital practice—particularly in French hospitals, where it is not the custom to give patients a bath on admission—the flexible pattern enables the physician or student to keep at arm's length from his patient, and his attention is less distracted by the noises around him. There are advantages, too, from the patient's point of view, for it is common experience in French hospitals to see a man seriously ill from typhoid fever or heart disease compelled to sit up in bed in order to permit of auscultation of the base of the lung, whereas when the binaural stethoscope is used it suffices to turn him on his side. Furthermore, the flexible stethoscope can be applied to the chest with a lighter touch than the rigid pattern. We have heard it said that our French colleagues' disregard for the binaural stethoscope must be due to a *not d'ordre*; for it is to be observed in all hospitals controlled by French medical men, from Paris to Algiers, from Lille to Bordeaux, and even students cannot be induced to give the instrument a trial, so strong is the force of the example set by their chiefs.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, 38, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

THE appointments of certifying factory surgeons at Canterbury (Kent) and West Bromwich (Stafford) are vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line...	0	1	6
Whole single column (three columns to page) ...	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so made.

Advertisements should be delivered, addressed to the Manager, later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *retail* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

400. Prognosis of Nephritis in Childhood.

A STUDY was undertaken by JAMES (*Journ. Amer. Med. Assoc.*, February 19th, 1921) to determine (1) how many patients that had had acute nephritis recovered entirely; (2) how many developed the chronic type; (3) the present condition of the chronic type, and (4) the ultimate prognosis. Sixty-seven children who had had nephritis in the last sixteen years were examined. The examination included the cardio-vascular system, haemoglobin, urinalysis, present health of the child, record of the patient's condition while under treatment, and the etiology. Nine of the 67 cases, or 13.3 per cent., terminated in the chronic type, and of these only 2 could be considered severe. All of the 67 patients who had had acute nephritis are living under normal conditions, on ordinary diet; and in every case the urine was found to be negative. Of 12 fatal acute exudative cases, one patient had an associated tuberculous peritonitis and one died of terminal pneumonia. Ten had general oedema, 2 died of uraemic convulsions; one patient having acute suppression of urine died following a decapsulation; one had associated acidosis. The point to be noted is that in none of the cases of the haemorrhagic type without oedema did the patients die in the acute stage of the disease. In the group of 12 chronic cases, 8 had albuminuria. In the urine of two patients, seen two years after discharge, a few red blood cells were found under high power. James believes that many patients with mild chronic nephritis recover. Diseased portions may recover even if there is considerable degeneration, and neighbouring portions of the kidney may hypertrophy and carry on the extra work. In other words, an anatomically imperfect kidney can function efficiently. Many children will stand severe infections without acute exacerbations of nephritis, but they are more prone to follow upper respiratory infections. For this reason all foci of infection should be treated, such as diseased tonsils, carious teeth, and otitis media (acute or chronic). They act as a reservoir of toxic material which the kidneys drain.

401. Prophylaxis of Hay Fever.

DETWEILER (*Canadian Med. Assoc. Journ.*, January, 1921) discusses the present-day conception of hay fever. In sensitive subjects the placing of the offending pollen upon the slightly abraded skin will cause a local reaction by the appearance of a wheal with a surrounding area of erythema. By this method of diagnosis the specific protein causing the disease can be ascertained, and the greatest success in treatment follows the prophylactic inoculation of the patient with a solution of the pollen protein. After grading the dilutions from 1 in 500 to 1 in 20,000, a preliminary skin test is made by placing a drop of the dilution upon a scratch and giving hypodermically as an initial dose 0.1 c.cm. of the dilution next higher than the one giving the positive skin test. Treatments should be given weekly, and should be completed by the time the attack is expected, so that the course of injections should begin three months before that time. Such a course should protect for a season, but it should be repeated each year for a few years. A change to a climate free from the offending pollen will be useful.

402. The Demonstration of Pleural Adhesions.

SAUGMAN (*Hospitalstidende*, January 19th, 1921) regretfully concludes that it is practically impossible to demonstrate the presence of pleural adhesions even when every diagnostic device is employed. He used to think that when there were marked excursions of the lungs, as determined by physical signs, and when the diaphragm was freely movable, both its vault and its circumference showing normal excursions, then the lung could not be adherent to the neighbouring structures. He found, however, that these signs could be present when the lung was adherent to the chest wall by means of a fine network of cobweb-like adhesions, which, though they allowed remarkably free movement of the lung on respiration, still prevented the effective collapse of the lung when gas was introduced into the pleural cavity. On the other hand, when the stethoscopic and x-ray examination, as well as the history of the case, pointed to complete obliteration of

the pleural space, he often found it perfectly free. In two cases he heard well-marked "friction" sounds, from which he concluded that the lung was not adherent at a certain point. In both cases, however, the lung proved to be firmly adherent at this point, and the sounds heard could not have been due to friction of one rough surface against another, but to creaking in the adherent area. The author admits that only by exploratory puncture can the presence or absence of pleural adhesions be demonstrated.

403. The Treatment of Pernicious Anaemia by Splenectomy.

FIFTY cases in which operation was performed more than three years ago are reviewed by GIFFIN and SZLAPKA (*Journ. Amer. Med. Assoc.*, January 29th, 1921). The immediate operative mortality of the series was 6 per cent. The deaths occurred in the first nineteen cases. The reduction of mortality is ascribed chiefly to more careful pre-operative treatment and the exclusion of the anemias of the more acute type. Forty-two of the forty-seven patients who recovered from operation have died. Ten (21.3 per cent.) lived longer than three years, while twenty-one (45 per cent.) lived longer than eighteen months after operation. Five (10.6 per cent.) of the forty-seven patients who recovered from operation are alive. Two were splenectomized four years and nine months ago, one four years and eight months, one four years and five months, and one four years and three months. These five patients at the time of their last reports were in good general condition. The pre-operative history of these patients in each case was approximately one year; the total average duration of the disease was considerably more than five years. Including with these the patients who survived operation at least three years but who are now dead, there is a total of ten (21.3 per cent.) in whom the total duration of disease before and after operation was four and a half years or more. This is clearly longer than the average expectation of life of patients with pernicious anaemia, and would seem to lead to the definite conclusion that life is prolonged in a considerable percentage of cases. On neurological examination before operation, twenty-nine patients (58 per cent.) showed definite evidence of sclerosis of the spinal cord. Eight more (16 per cent.) registered complaints suggestive of early involvement of the spinal cord, making a total of thirty-seven patients (74 per cent.). Marked degeneration of the cords has not progressed in patients in whom the degeneration was slight previous to splenectomy. It is possible that the progress of the degeneration is arrested in some of the patients. Mental symptoms have not developed following operation. In the selection of patients for operation in this series preference was given to persons between the ages of 35 and 45, with a previous history of one year or less, a favourable type of blood picture, and with little if any evidence of degeneration of the spinal cord. An absence of marked leucopenia with a polymorphonuclear rather than a lymphocytic predominance in the leucocyte count, marked haemolytic activity, estimated by the examination of the pigments in the duodenal contents in the presence of a competent bone marrow and a moderately enlarged spleen, were regarded as favourable to splenectomy. Patients in acute exacerbations and patients showing evidence of bone marrow exhaustion were excluded so far as possible. The histories of the surviving patients are given in full.

404. Laryngeal and Pharyngeal Crises in Influenza.

CURSCHMANN (*Deut. med. Woch.*, February 10th, 1921) gives an account of laryngo- and pharyngo-spasm as a sequel to influenza. Two of the patients whose histories he gives were professors of medicine, the author himself being one. Another patient was a nurse, aged 52, and there were two other patients, aged 35 and 41 respectively. In the author's own case the attacks occurred at night, and he used to awake with a fit of coughing and a sensation of being throttled. For a few seconds he could not breathe. The regular prophylactic administration of codeine gradually aborted these attacks. Discussing their etiology, the author notes that tabes, tetany, polyneuritis, bronchial asthma, whooping-cough, and neuroses could be excluded in every case. In all but one case the laryngoscopic picture was normal except for slight redness and injection. Clinically the condition closely resembled the laryngeal and pharyngeal crises of tabes; but whereas in tabes the central end of the vagus is involved, it is

probable that in influenza this condition is due to involvement of the terminations of the vagus in the pharynx and larynx. A curious accompaniment to this spasmodic condition was irrepressible diarrhoea which led to very disagreeable distension. The importance of the diagnosis of which is the central nervous system, such as tabes.

405. Diagnosis and Prognosis of Persistent Ductus Arteriosus.

ACCORDING to BUDDE (*Zentralbl. f. inn. Med.*, February 12th, 1921), the diagnosis of persistent ductus arteriosus may be established by the following considerations: (1) The history of a congenital heart disease; (2) entire absence or late occurrence of cyanosis, which is usually not of a very high degree; (3) moderate enlargement of the heart; (4) visible pulsation and a palpable thrill in the second left intercostal space; (5) loud systolic and occasionally also diastolic murmur in the second left intercostal space conducted into the vessels of the neck and interscapular space; there is also a greatly accentuated second pulmonary sound; (6) on very deep inspiration there is a diminution of the murmur and pulsation. The prognosis as regards life is not very unfavourable, as there is at least one case on record of the patient reaching the age of 58. As a general rule, however, a disturbance of compensation occurs as the result of strain, intercurrent disease, or during puberty, and the condition then resembles ordinary heart disease with failure of compensation. It should be noted that a pulmonary artery which is constantly under a high pressure is very liable to sclerotic changes. Moreover, endarteritic processes, as Wegener, Rickards, and others have shown, have a special tendency to develop in or around a patent ductus arteriosus, which therefore forms a *locus minoris resistentiae*. Rupture of the patent ductus arteriosus may also occur.

406. The Incidence and Treatment of Cerebro-spinal Syphilis.

HANSEN (*Acta Medica Scandinavica*, January 14th, 1921) is greatly impressed by the comparative frequency of cerebro-spinal syphilis in Bergen, where, in 1917 and 1918, among 2,464 patients, Wassermann's reaction was carried out in 440 cases, and was found to be positive in 96. In 53 of these 96 cases cerebro-spinal syphilis was diagnosed, tabes and general paralysis being included in this category. The author gives the three following possible explanations for this high rate of cerebro-spinal syphilis: (1) In 1898, the year of an exhibition in Bergen, there were extraordinarily many cases of syphilitic infection. The cerebro-spinal syphilis two decades later may be the sequel to this crop of infections. (2) Cerebro-spinal localization of syphilis may have been promoted by salvarsan treatment. (3) Bergen being one of the busiest ports in Europe during the war, the number of sailors among the syphilitic was very high, and in this class the incidence of cerebro-spinal syphilis is remarkably great. Thus 25 per cent. of the sailors admitted to an asylum in Bergen suffered from general paralysis, whereas of the total number of lunatics admitted in a ten-year period only 3 per cent. suffered from general paralysis. The author advocates supplementing salvarsan treatment with mercury and potassium iodide. He has nothing good to say of the intrathecal administration of neo-salvarsan.

407. The Etiological Relationship between Congenital Anomalies and Hereditary Syphilis.

DE STEFANO (*La Pediatria*, January 31st, 1921) examined 272 cases of congenital anomalies and malformations at the Naples University Paediatric Clinic for the presence of hereditary syphilis, the presence of which was determined by the history, association of other morbid symptoms, and the results of the Wassermann reaction carried out simultaneously on the children and their parents. The cases included 54 of hydrocephalus, in which syphilis was found in 50; 23 of spina bifida, 9 of which were positive; 69 of congenital heart disease, 27 of which were positive; 46 of mongolian hypothyroidism, 59 of which were positive; and 17 pluriglandular idiocy, 34 of which were positive. The cases thus syndromes, of which 15 were positive. The cases thus show the great frequency of congenital syphilis in the etiology of congenital anomalies and malformations, although it is not the exclusive cause. This is a matter of very great importance, especially from the prophylactic standpoint, because a rational treatment of syphilis in the parents, combined with a careful hygiene of pregnancy, ought to prevent to a certain extent the occurrence of a large number of congenital defects.

SURGERY.

408. Fate of Transplanted Bone.

LERICHE and POLICARD (*Lyon Chir.*, July-August, 1920) make an important analysis of the fate of transplanted bone. They point out that a bone graft is not a true graft, because the actual bony tissue transplanted always dies. This death is invariable, however good the conditions may be. It is true that sometimes a few bone cells may survive beneath the periosteum, but even then the whole of the rest of the bone dies. Many surgeons argue that the transplant survives as a living graft, because on re-exploration they have found the bone well vascularized and bleeding readily when cut, because the transplant has perhaps fulfilled its therapeutic purpose and is fixed at its extremities, because it has increased in size, because it has consolidated after fracture. Leriche and Policard believe that these arguments have not the least value. There is in all this an appearance of life only; the sole criterion is histological examination, and by this standard all bone grafts die. The authors state that there are only three possible fates for transplanted bone: elimination, toleration, absorption; of these the last is the common one. Capillary buds grow into the Haversian canals and enlarge their lumina, revascularizing the bone, making it spongy and permeable. Thus compact bone, crest of the tibia, and segments of fibula are by no means the best material for transplanting. The process of absorption is only delayed, it cannot be obviated. Fractures of the graft are very common, occur even in limbs perfectly immobilized by apparatus, and are often unrecognized. In one of the authors' cases three fractures occurred in one year, but united and left no trace. Concurrently with the bone absorption, layers of new bone are laid down and these not only within the actual area of the transplant but especially in its neighbourhood. The process is one of new bone formation and not one of growth of the transplant *in situ*. Dead bone should do as well as fresh autogenous bone; but, as the authors point out, the beef and horse bone used is too thick and compact, and resists vascularization too long. They lay stress on the retarding influence of fibrous tissue owing to its relative anaemia, and on the importance of obtaining good apposition at the ends of the transplant. These observations are based on an examination of bone removed from 15 transplantations, and on the clinical findings in 29 bone-grafts done by themselves.

Oesophageal Stricture.

409. AUSTONI (*Archiv. Ital. di Chirurg.*, December 20th, 1920), as the result of a somewhat exceptional experience in the treatment of oesophageal stricture (chiefly of traumatic origin), says that surgical treatment should be started as early as possible. The stricture should be dilated with sounds; if high up in the oesophagus, the oesophagoscope should be used and sounds passed through the mouth; if at the lower end, it is better to use the gastroscope and the pass instruments the reverse way—namely, through the stomach. Where the lesion is extensive it is well to practise intubation at the outset, and this is better done through the stomach. Absolute stenosis is extremely rare usually a guide can at least be passed through the stricture. When passing sounds through the stomach, the cardiac opening can be found more easily if a little milk is swallowed. In old strictures treatment may have to be continued for three or four months, but in recent cases a shorter time is sufficient. After cure is obtained, an instrument should be passed every month for about a year. Injections of fibrolysin seem to assist the progress of the cure.

Chronic Appendicitis.

410. CONNELLI (*Med. Record*, February 5th, 1921) shows that certain cases of so-called chronic appendicitis are due to causes other than the appendix, the symptoms not being relieved by appendicectomy. The pain and tenderness in the right iliac fossa may not be due to adhesions, and the cause of the symptoms would seem to be more central than in the appendix itself, either in the mucosa or wall of the caecum or colon, the ileo-caecal valve, the root of the mesentery, or even still more centrally in the vagus or sympathetic nerve supply, or in the ductless glands. The previous history as to earlier attacks is important, and supposed cases of chronic appendicitis may be subdivided into those with and those without a history of a previous attack, and a more careful physical examination and consideration of all the facts is strongly urged before an operation is undertaken for a so-called chronic appendicitis.

311. Sapheno-femoral Anastomosis.

MANTELLI (*La Clin. Chirurg.*, May, 1920) discusses Delbert's sapheno-femoral anastomosis operation for varicose veins of the internal saphenous. After discussing the technique, immediate and remote results of the operation, and the literature of the subject, he says the indications for the operation are: (1) Good general condition of the patient; (2) varicose veins of the internal saphenous; (3) presence of Trendelenburg's sign; (4) varices of recent formation where the veins have kept to some extent their elasticity and contractility; (5) perviousness of the saphena and absence of all sign of inflammation. The author has performed 9 sapheno-femoral anastomoses with the following results: Anatomical and functional cure, 1; functional but only partial anatomical cure, 3; functional cure only, 2; doubtful issue, 1; bad results, 2. Of the bad results, one was owing to the presence of varices in the branches of the external saphenous vein (not recognized before operation in 1912), and the other was due to the onset of deep varicose veins a few months after the operation in a patient who had already suffered from phlebitis secondary to typhus. When the internal saphenous vein and its branches are alone affected the operation is an ideal one.

312. Extension of Renal Tuberculosis.

CRASTREE (*Arch. of Surg.*, November, 1920) has studied the lymphatic spread of tuberculosis within the kidney. It is generally recognized that a primary tuberculous patch in the kidney is almost invariably situated in the region of the medullary portion at the base of a pyramid. Extension causes it to burst into the pelvis of the ureter, which is nearer than the cortex. A tuberculous pyelitis is now instituted, and is sufficient in itself to justify nephrectomy. Tubercle bacilli are found in greatest numbers in the recesses of the calyces, these being backwaters of urinary irrigation. From the pelvis a reinvasion of the kidney parenchyma occurs, probably along the lumen of the tubules. Crastree has repeated Ekeborn's work and confirms it. He has found in apparently normal portions of the cortex, remote from the primary focus, microscopical tubercles just beneath the true capsule. As he could find no connexion between these tubercles and the deeper parts of the renal substance, he believes them to have originated from a lateral extension by the cortical lymphatics. He believes, however, that with these cortical tubercles as a starting point secondary tubercles may form in the renal cortex, and that these may be of considerable importance in encompassing the destruction of the kidney.

313. Tuberculosis of the Ear.

LERNOYEZ (*Ann. des mal. de l'oreille*, vol. xl, Nos. 10-12), after stating that tuberculosis of the external ear is usually confined to the pinna, and that tuberculosis of the internal ear is exceptional, confines his attention to tuberculosis of the middle ear. The apparent difficulty in the diagnosis of tuberculosis of the middle ear is due to its insidious character and its protean manifestations. The disease may develop in persons who are in apparently good health, in whom it assumes the appearance of an ordinary otitis media. It is important to realize that every case of tuberculous otitis does not necessarily occur in a phthisical subject. On the other hand, only 60 per cent. of the cases of otorrhoea in phthisical patients are tuberculous. The protean manifestations of tuberculosis of the middle ear are as follows: (1) Otorrhoea, which is its ordinary symptom, corresponds to at least four distinct types of lesions of the middle ear, which Brieger designated as lupoid, infiltrative, fungous, and necrotic types respectively. (2) The appearance of the tympanum is often but not always characterized by multiple perforations. Sometimes the otoscope shows a milky tuberculous exudate, nodules (acute tuberculous otitis), or on the other hand, a soft yellowish swelling (chronic tuberculous myringitis). (3) Tuberculosis may produce an osteo-periostitis of the mastoid process, which sometimes has such a slow course that it has been attributed to the bovine type of the tubercle bacillus. (4) Suppuration of any kind may be absent, and the resulting dry tuberculous otitis behaves like an acute or chronic catarrh of the tympanum. The complications of tuberculous otitis media are labyrinthine paralysis, facial paralysis, perforation of the internal carotid, and external pachymeningitis. The prognosis is grave, partly owing to these complications and partly owing to tuberculous lesions in other organs. It is worst in early life, especially in infants. Relapses are frequent.

OBSTETRICS AND GYNAECOLOGY.**314. A Sign of Pregnancy.**

DEZWARTE (*Paris méd.*, February 12th, 1921) describes a sign which is based on the position of normal equilibrium and normal mobility of the uterus, and is therefore absent in cases of deviation or abnormal fixation of the organ. In the normal state the uterus is ante-flexed, and on vaginal examination the finger successively distinguishes the anterior lip of the cervix, the external os, the posterior lip, and the posterior vaginal cul-de-sac. Just before menstruation and in pregnancy the uterus becomes retro-flexed, and on vaginal examination the os externum will at once be encountered, as it is now in the axis of the vaginal canal.

315. Operations for Myoma.

HORNUNG (*Zentralbl. f. Gynäk.*, March 12th, 1921) records 447 operations for uterine myoma at the Kiel Frauenklinik. The ages of the patients were: Below 25 years, 1; 25 to 30, 2.6 per cent.; 31 to 35, 6.9 per cent.; 36 to 40, 19.4 per cent.; 41 to 45, 23.8 per cent.; 46 to 50, 31.4 per cent.; 51 to 60, 13.4 per cent.; over 60, 2.5 per cent. Only 115 (25.7 per cent.) were nulliparous. Symptomatic bleeding occurred in 43 per cent. of cases, menorrhagia being twice as common as metrorrhagia. Dysuria or urinary incontinence occurred in 25 per cent.; in about 15 per cent. there were signs of cardiac impairment, consecutive, probably, to the loss of blood. In 9 cases only (2 per cent.) was sarcomatous transformation of the myoma established; cancer of the uterine body coexisted in 5 cases, of the neck in 2. Cases of regressive change in the myomata numbered 11.6 per cent.—necrosis (total or partial) in 20 instances, softening with cyst formation in 17, hyaline degeneration in 7, calcification in 7. In 33 cases only was the myomatous uterus adherent to neighbouring viscera. In 12 cases the myoma was confined to the cervix. The total mortality in this series was 1.79 per cent. The operations employed were: Vaginal extirpation (total), 175, with no death; abdominal extirpation (total), 174, with 7 deaths; supravaginal amputation, 36, with no deaths; abdominal enucleation, 23, with 1 death; conservative vaginal operation, 39, with no death. The adnexa were removed at operation—on both sides in 45 per cent. of cases, on one side in 17.6 per cent. Thrombosis, infarction of the lung, or embolus, followed 1.4 per cent. of 214 vaginal operations, and 4.72 per cent. of 233 abdominal operations. The author concludes that whenever it is possible for removal of myomata not larger than the closed fist, the vaginal route should be selected; in the case of nulliparae additional space may be gained by using Schuchardt's paravaginal incision. In cases where it is desired to treat conservatively intramural or subserous myomata of the body, Hornung argues, however, that the vaginal approach (as compared with the abdominal) leads to more formidable operative difficulties and to greater danger of infection.

316. Radium Treatment of Haemorrhage at the Climacteric.

EBELER (*Med. Klinik*, 1920, 43 and 44) describes the treatment by radium of 52 cases of "metropathica haemorrhagica" occurring about the menopause. On account of the subsequent occurrence of occasional cases of cervical stenosis with pyometra, intrauterine application was abandoned, and the radium, enveloped by gauze and indiarubber and ensheathed in a silver tube, was placed in the anterior or posterior vaginal fornix, in dosage of 26.5 mg., for eight to twenty-four hours. The applications were made on successive days, or separated by intervals of from two to seven days, and in nearly all cases two series of treatments, between which a single period of menstruation intervened, were found to be sufficient. In 19 of the 52 cases no further menstruation occurred after the completion of the treatment; in 14 cases one period ensued, and in 9 cases two. Of the remaining 10 cases, menstruation became definitely diminished in 7. The author believes that with proper control of the dosage radium treatment of these cases is as useful as x-ray therapy.

317. Management of Labour after Previous Caesarean Section.

In discussing the debatable point of the treatment of a woman in labour who has had a previous Caesarean section VANVERTS (*Gaz. des Praticiens*, March, 1921) quotes six of his own cases, in which two had a normal confinement after previous Caesarean section, and four were treated by repeating Caesarean section. One of the

latter ruptured, and it was necessary to do a hysterectomy. His conclusions are, that a patient who has had a previous Caesarean section should be allowed to go into labour, and if the head engages easily labour may safely be allowed to continue; but if there is any difficulty about the head engaging, a Caesarean section should at once be performed.

PATHOLOGY.

418.

Cultivation of the Gonococcus.

SWARTZ, SHOHL, and DAVIES (*Bull. Johns Hopkins Hosp.*, December, 1920), after investigation of various factors affecting the growth of gonococci in culture, state that the essential factor is reduced oxygen tension. Moisture is also necessary for good growth. A reduction in the oxygen tension of 10 per cent. is sufficient to produce optimal growth. The organism will grow luxuriantly, if the oxygen tension is suitable and moisture and uncoagulated protein are present, on media of ordinary reaction range. The technique is very simple. Ordinary broth agar (2 per cent.) is melted, and to it is added half as much sterile ascitic fluid. The tubes are sealed with sterile rubber stoppers, slanted, and kept always in the incubator. They are copiously inoculated, care being taken to prevent cooling, and the inoculated tubes held horizontally, with the agar uppermost, are passed three or four times through the Bunsen flame and quickly corked. This is quite sufficient to lower the oxygen pressure to the requisite degree, when the tubes are returned to the lower incubator temperature. Colonies are visible in from fifteen to eighteen hours, and profuse growth is obtained in twenty-four hours. On this medium the gonococcus is viable for about seven days.

419. Serum Diagnosis of Tuberculosis of Cattle.

HRUSKA and PFENNINGER (*Annales de l'Inst. Pasteur*, January, 1921), using the complement deviation method with Besredka's antigen, and taking the blood direct from the hearts of cattle slaughtered at the abattoir, have been able to bring the serological findings into direct relationship with the post-mortem appearances presented by the cattle. Of 324 cattle showing tuberculous lesions, 84.5 per cent. gave a positive fixation reaction. On the other hand, 2.2 per cent. of cattle in which no naked-eye evidence of tuberculosis was found also gave a positive reaction. Going more particularly into the figures, it was found that there was some relation between the extent of the disease and the result of the reaction. Thus, in slight cases a positive reaction was recorded in 60 per cent., with more widespread lesions the reaction was positive in from 84 to 95 per cent., whilst in cases of generalized tuberculosis fully 100 per cent. of positive results were obtained, even though the animals appeared to be in good condition. The authors therefore regard the complement deviation reaction as much more certain than the ophthalmoreaction usually employed in the diagnosis of tuberculosis in cattle. It is interesting to note that the particular antigen employed was prepared from "human" tubercle bacilli, and it gave better results when compared throughout the tests with a similar antigen prepared from bovine strains.

420. Experimental Encephalitis Lethargica.

LEVADITI and HARVIER (*C. R. Soc. Biologie*, February 12th, 1921) have discovered that it is possible to transmit the virus (which is preserved by passage through rabbits) to mice not only by intracerebral injection but, strangely enough, by intraperitoneal and subcutaneous injection, to which rabbits and other animals are refractory. In the case of mice there is an incubation period of two to three days after intracerebral injection and a period of eight days when the injection is made into the peritoneum or under the skin. The authors also record the production of encephalitic keratitis and transmission of the disease by corneal inoculation. An important finding is that the virus remains alive at room temperature for at least sixty days in milk and fifteen days in water. This renders plausible the supposition that water, and especially milk, may play the rôle of vectors of the virus in the propagation of epidemic encephalitis.

421. Primary Tumours of the Vagina.

PICCAGNONI (*Il Policlinico*, Sez. Chir., January 15th, 1921) states that primary tumours of the vagina are rare occurrences. Epitheliomata are uncommon, fibromyomata and pure fibromata and myomata are rarer still, and sarcomata rarest of all. Fibromyoma appears by preference between

the ages of 30 and 40. As a rule, it is isolated and grows in the anterior wall of the vagina. Sometimes, instead of growing in the fibromuscular coat of the vagina, it descends from the uterus or parametrium, to which it may be attached by a pedicle (migratory fibroma). Histologically, it consists of fibrous tissue combined with smooth muscular fibres and numerous thick-walled blood vessels. Fibrous tumours of the vagina, though not essentially malignant, may by their large size give rise to severe dystocia or cause compression of neighbouring organs. At a certain period of their development they may produce haemorrhage or suppuration. Their gravity may also be due to the degenerative changes to which they are liable—namely, telangiectases, gangrene, and sarcoma. Treatment consists in enucleation of the tumour by isolating it from the vagina. Sarcoma of the vagina differs in its appearance according as it occurs in childhood or adult life. In children it almost always grows in the anterior vaginal wall in the form of a bunch of grapes, and may be latent for a certain time and then give rise to severe haemorrhage. Its growth is extensive *in situ*, but it usually does not give rise to metastases in distant organs. In adults it usually occurs from 30 to 40, grows indifferently in the anterior and posterior vaginal wall, is rounded, usually sessile, and is at first covered by normal mucous membrane. Subsequently it may ulcerate, and give rise to metastases in the lymph glands, peritoneum, and lungs. Histologically vaginal sarcoma consists of spindle cells, and contains numerous blood vessels and interstitial haemorrhages. It is of exceptional gravity, and always recurs after removal. Primary epithelioma of the vagina is most frequent between 50 and 60. It has a predilection for the upper part of the posterior wall. It may appear in a papillary or vegetative form. Sometimes it extends all round the vagina, forming the so-called annular cancer. The symptoms consist of purulent foetid discharge, marked haemorrhage, rectal and vesical disturbance, and neuralgia of the lower limbs when the growth invades the pelvis. The prognosis is grave, and recurrence always occurs after removal. Treatment consists in partial or complete removal of the vagina or in the application of radium.

422. Experimental Exposure of the Pituitary to X Rays.

GELLER (Inaug. Dissert., Breslau, 1920, and *Zentralbl. f. Gynäk.*, March 5th, 1921) describes the results of experimental irradiation of the pituitary in nulliparous rabbits. He noted an apparent checking of growth in the hypophysis, especially in the anterior lobe and the pars intermedia; histologically the small cells were most affected, especially perhaps the young forms of the large chromophile cells. The ovarian cells showed no characteristic alterations in appearance. The rate of growth of the animals appeared to be diminished. Similar treatment of a case of dystrophy adiposo-genitalis was followed by increase of menstruation without alteration in the external habitus.

423. Histological Lesions in a Case of Rabies.

MARCHANT (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 30th, 1920) gives the following description of the histological examination of a man who died of rabies six weeks after being bitten by a dog. The illness lasted four days. The diagnosis was confirmed by inoculation of an emulsion of the patient's medulla into an animal giving a positive result. The autopsy was confined to the brain. No naked-eye lesions were seen. Histologically the cerebrum was intact, the lesions being confined to the medulla oblongata, where they consisted of perivascular inflammation chiefly affecting the vessels of the floor of the fourth ventricle, very slight inflammatory areas in the other bulbar regions, and definite chromatolysis of the cells of the cranial nuclei. There was an absence of Negri bodies.

424. Epithelioma Arising in Lupus Erythematosus

WANDER (*Arch. of Derm. and Syph.*, January, 1921), in reporting four cases of epithelioma developing on lupus erythematosus, calls attention to the surprising rarity of this occurrence. From the chronicity of lupus erythematosus and the prolonged irritation from treatment, one might expect the resulting continuous trauma to lead to frequent development of carcinoma on such a favourable base. All traumas when sufficiently prolonged are potentially stimuli to cancer formation. In the cases already reported multiple foci of origin are the rule and rapid spread of the disease. In Wander's cases, three of whom were over 60 years of age, the lupus erythematosus had lasted for twelve to twenty-four years when carcinoma developed.

"It is a fatal error to expect the milk of a foreign species to be immediately adapted to and utilized by the human infant; the differences between that of the woman and that of a lower animal would indicate, even when given to the newly born with normal functions, that we must wait until the delicate digestive and assimilative organs can make use of the material designed for a more vigorous animal."

Increase in Use of Glaxo Decline in Infant Mortality

Many factors have combined to bring about the remarkable decline in infant mortality during recent years, but there must be few who will not now concede that the replacement of far-inacious foods and infective raw milk by properly prepared standardised dried milk has been a factor of some importance in this work. This chart shows the increase in Glaxo sales during recent years in comparison with the annual infant mortality rate over the same period.

A Clinical Lecture ON THE ORTHOPAEDIC TREATMENT OF POLIOMYELITIS.*

BY

H. A. T. FAIRBANK, D.S.O., O.B.E., M.S., ETC.,

SENIOR ORTHOPAEDIC SURGEON TO KING'S COLLEGE HOSPITAL;
SURGEON TO THE HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET.

The surgical treatment of poliomyelitis includes a great deal which can be carried out by any practitioner, whether physician, surgeon, or both.

It is customary for purposes of treatment to divide the course of a case into three stages: the early, acute stage, which lasts while there is pain and tenderness in the muscles; the second or convalescent stage, during which the recovery of power is taking place—it lasts to the end of the first and sometimes the end of the second year; and the third stage, which begins after the lapse of two years: until this stage all reconstructive surgery is delayed.

FIRST STAGE.

During the first stage the spinal cord is the seat of a haemorrhagic inflammation, which is gradually subsiding. Those anterior horn cells which have been only temporarily thrown out of action gradually return to health and perform their normal functions, while others which have been damaged too severely to recover degenerate. The flaccid paralysis affects a more or less wide range of muscles—very often a much wider range than would be suspected from an examination of the patient a few months later.

Unfortunately we cannot tell at first which muscles will recover rapidly, which will recover more or less completely though slowly, and which will remain completely paralysed. Therefore we must treat all the muscles alike until such time as recovery indicates which require special care.

The first essential of treatment is rest, both for the spinal cord and the affected muscles. All patients are best kept in bed for a time; Batten¹ insisted on three weeks, even in mild cases. Steps should be taken to provide absolute rest for all the affected muscles, and this involves rest for all their opponents as well should these not be paralysed. There seems to be a great tendency to delay doing anything, particularly in a bad case, until the acute stage has passed off. This is, I think, a mistake. Splints or other fixation apparatus should be applied at the earliest possible moment, the limbs being fixed in the neutral position. Without fixation deformities are certain to occur. The apophthegm, "Prevention is better than cure," applies with as much force in this instance as in any other. The neutral position is one in which, as far as possible, no one muscle or group of muscles around a joint is favoured to the detriment of others. Thus the foot is put at a right angle, the knees are straight, the hips are straight and the spine flat. The position of the hip and knee joints can be assured by rest on a flat bed, with a towel and a couple of sandbags to keep the knee from flexing, but the feet require some simple splint of tin, wood or plaster-of-Paris to hold them at the right angle. As regards the arm, the best position is one of abduction of the shoulder, flexion of the elbow to a right angle, supination of the forearm and dorsiflexion of the wrist. This position is not entirely governed by a desire to find the neutral position, but partly with an eye to favouring those muscles which we know recover with difficulty, and of which the recovery is more important than that of their opponents; for instance, the deltoid, biceps, etc. This position can be retained by sandbags while the patient is lying flat, but a splint is necessary as soon as he sits or stands. The simplest splint is one made of tin. Such splints serve a double purpose—to give rest and to prevent deformity.

As regards the correction of deformity at this stage, it will be found easy to stretch contracted muscles. When the muscles are still tender, except in cases where this tenderness is unduly prolonged, very gentle persuasive

manipulations with fixation on a splint which is slightly altered in shape each day will achieve correction of the deformity. The stretching is painful, and must be done with the greatest gentleness; if the foot is fixed in the position which is the best possible one day, it will usually be found possible to improve this slightly the next.

Lovett and Richardson,² in 604 cases, found that in 49 per cent. the pain and tenderness had disappeared by the end of the second week, and in a further 13 per cent. by the end of the fourth week, and that it was quite exceptional to find any tenderness after the second month.

Massage should be carried out with the greatest gentleness, and one must be guided by its effect in each case. If the patient cannot stand even gentle massage, it must be discontinued. Lovett³ considers it harmful, as since it is painful it irritates an already inflamed cord, and he forbids it absolutely while there is tenderness. In the majority of cases, if done properly, it should not be painful and can do no harm, and it unquestionably prevents some of the wasting of the muscles. Electricity is useless at this stage.

A word of caution seems to be called for with regard to the spinal muscles. There are undoubtedly cases which develop a spinal curve while still lying flat on the back, the position they have been in since the onset of the disease; there are others in which the onset of lateral curvature has been less rapid, but in which a distinct cause is present in the unequal affection or recovery of the muscles of the two sides of the body, or of the two legs, etc.; but there are some cases of scoliosis seen at a later stage which make one wonder whether they ought not to have been prevented. In such cases a special cause for the deformity is absent, all portions of the erector spinae acting well. One cannot exclude unequal power in the two erectors spinae as the cause, but this could equally well have resulted from the stretching of the muscles on the convex side of the curve and relaxation of those on the concave side—that is, it is the result and not the cause of the curvature. A case in which the spinal muscles, though slightly affected at first, have recovered, but still remain weak when the child first begins to sit up, is just the subject for scoliosis. I would urge the advisability of raising the child to a sitting position slowly and gradually by means of a bed rest and pillows. The spinal muscles should be massaged, and any paresis and tendency to curvature looked for.

The possible causes of scoliosis in poliomyelitis cases are:

1. Paralysis or weakness of (a) the spinal muscles on one side; (b) the abdominal muscles in one loin, and of the intercostals on one side; (c) of one psoas (as first suggested by Elmslie).
2. General weakness of all the spinal and accessory muscles.
3. Contracture of one hip.
4. Shortness of one leg.
5. Paralysis of one shoulder.

SECOND STAGE.

There is no question that signs of recovery may appear in muscles previously paralysed up to the end of the first year. In a case treated well throughout, a muscle which is absolutely paralysed after twelve months must be regarded as hopeless (Jones).⁴ During the second year further recovery may take place in all those which have to some extent recovered, but a muscle which remains paralysed for many months before showing any return of power will never be of much use to the patient.

The treatment during the second stage comprises the following: Keeping the part warm, relaxation of the paralysed or weak muscles, massage and re-education of muscles, to which must be added "correction of deformity," if such has been allowed to occur. Additional covering for a paralysed limb is essential even in the summer months. The difference in power of a cold and a warm muscle is surprising.

The next point is, in my opinion, the most important. Without adequate support recovery is bound to be far from complete, and will be coupled with deformity. Unfortunately the efficient use of splints is a factor in treatment most often neglected. It is not at all uncommon to find a patient in whom deformities have occurred provided with beautiful walking apparatus, but the use of night splints has been omitted. Splints are more efficient correctors of a tendency to deformity than any walking

* Delivered at the Hospital for Sick Children, Great Ormond Street, on October 23rd, 1920.

apparatus. Thanks largely to Sir Robert Jones's repeated utterances on this subject, it is now generally agreed that avoidance of over-stretching of a paralysed muscle, particularly in the early stages of its recovery, is essential for good recovery. The wisdom or necessity of carrying this to the extent of never for an instant allowing any paralysed or weak muscle to be stretched even to a moderate degree, has been questioned by Langley.² Whether this prevention of over-stretching should be carried to the extent of absolute relaxation—or, in other words, whether the neutral position is sufficient—or whether the limb should be put in a position to relax the paralysed muscles at the expense of their unparalysed opponents, is still an open question. If all the muscles of a limb are paralysed, the neutral position is, of course, the correct one; but supposing the anterior tibial group paralysed, and the tendo Achillis muscles acting, there is a strong tendency to equinus, and I think the best position is one of slight calcaneus, for a certain amount of slipping of bandages can then occur without the foot dropping beyond a right angle. Moreover, we not only want to see power returning in the anterior muscles, but we want to see equilibrium established between the anterior and posterior muscles at the earliest possible moment, so that apparatus may be gradually discarded. Some weakening by stretching of the opponents, therefore, is not altogether inadvisable in such a case.

One word of warning must be given as to the bandages or straps used to hold a limb in a splint. In the case of the leg these should encircle the foot and ankle and, at most, the lower third of the leg; the muscles themselves should be free of all pressure.

The splints must be left on day and night, and removed only for washing, massage, etc., when the position of the limb should be maintained by the hand of the attendant so long as any marked degree of weakness persists. The different methods of fixation for different parts of the body will be referred to later. As soon as recovery has progressed sufficiently walking should be encouraged, suitable apparatus being employed. So important do I consider the fixation of the part and the relaxation of the paralysed muscles that in certain difficult cases where the supervision of splints, etc., has been most inadequate I have applied an irremovable plaster-of-Paris case, with gratifying results; on removal of the plaster a month or two later, a muscle which had previously shown no flicker of voluntary power has been found acting strongly. This method may be used with advantage in cases other than poliomyelitis, where one muscle or group of muscles has been weakened or paralysed by persistent over-stretching.

Re-education of Muscles.

This is a term of which we have heard much in recent years, but it means nothing more than exercises carried out with a minute regard for the development of individual muscles. Enormous improvements have taken place in this branch of treatment recently as the result of medical men giving careful attention to the subject instead of leaving the cases to masseuses. W. Colin Mackenzie's⁶ name will always be associated with this work. Mackay⁷ recently published an excellent paper on infantile paralysis, from the point of view particularly of splinting and re-education. There is no doubt that active exercises are the best means of increasing the power of a weak muscle, provided that muscle has recovered sufficiently to contract voluntarily. Massage may improve nutrition, and more particularly check malnutrition, but it cannot cause a muscle to hypertrophy; alternate contraction and relaxation repeated over and over again can alone accomplish this. Normal voluntary contraction is always to be preferred, though electrical stimulation, when applicable, comes next in usefulness because it produces contraction.

A very important point always to keep in mind in the re-education of muscle is to make the load proportionate to the power of the muscle. It is worse than useless to try and make a partially recovered but very weak muscle produce a movement against the force of gravity. To put gravity out of court the limb is placed so that the muscles to be exercised move the part in a horizontal plane. To make it easier for this movement to be performed with the limb resting, the latter is often placed on a board sprinkled with powder to make it slippery. By this and other means the patient is induced to contract even the weakest muscles

over which he has any control. Fatigue is to be avoided at all costs, therefore constant skilled attention during the performance of exercises is essential.

Recovery can take place, particularly when the damage is slight, without any special treatment in the way of re-education, and this without deformity, provided splints have been employed, but without splints anything approaching perfection is impossible.

Massage should be continued with slightly greater vigour, but it is always well to keep in mind, as Sir Robert Jones⁸ has pointed out, that a paralysed muscle may be damaged by heavy manipulation. If a tendency to deformity in any one direction is present, the foot should be manipulated in the opposite direction so as to prevent the occurrence of contractures. This is a most important detail, and should be carried out morning and evening by the nurse or attendant. It is often asked after one, two, or more years have passed since the onset of the disease, "Is it any good going on with massage?" My reply is, "The more that limb is massaged, the more it is exercised, and the greater the care taken in keeping it warm, the less will it lag behind its fellow in growth, and the smaller will be the increase in the 'shortening' as the child grows up."

As regards electrical treatment, we must remember that there is a great deal of difference between a child with poliomyelitis and an adult with, say, a musculo-spiral paresis. In the latter it is easy to pick out individual muscles, and, moreover, the patient will readily stand the discomfort of the treatment, whereas in a child a stronger current is necessary to penetrate the relatively thicker layer of skin and fat overlying the shrunken muscles, so that a stimulus sufficient to cause contraction is too painful to be borne by the child; as Batten⁹ insisted, such a current usually causes contraction of the healthy opponents, and results in stretching rather than in active shortening of the muscles we are attempting to treat. In older children—and children vary considerably in how much they feel the faradic current—this method should be employed when practicable. In the majority of cases it will be found more worthy than it is worth. This holds good for both the galvanic and the faradic currents. As regards other forms of electrical treatment, I must confess myself sceptical. Whether an electric bath with a uniform current passing through it does more than stimulate the skin I am very doubtful. As a means of diagnosis the faradic current is useful; it confirms our clinical diagnosis as to which muscles are really paralysed.

DEFORMITIES.

The causes of deformity are gravity and the inability of a weak or paralysed group of muscles to elongate their opponents after the latter have contracted. These two causes may work together or separately. A deformity becomes fixed, that is, incorrigible by ordinary manipulation, as the result of contracture of unparalysed or stronger muscles; after a time there will be in the neighbourhood accommodative changes in the ligaments, bones, and other tissues. If the muscle is due to the shrinking of the tissue which binds the fasciculi together into an anatomical muscle. If this is not stretched in the normal way by contraction of opponents or by daily manipulations, it becomes permanently short and elongation is impossible.

It is, perhaps, not generally recognized that a totally paralysed muscle in poliomyelitis cannot become contracted, and that contracture of a muscle is proof of some, though perhaps not very obvious, recovery of tone in that muscle. As an example, equinus does not result when all the muscles below the knee are paralysed, even though the foot has been unsupported by a splint; in such a case a stiff ankle results. If any shortening of the tendo Achillis muscles is present there must be some return of power in the calf which should be capable of further development, though possibly not to the extent of being useful to the patient.

It sometimes happens that one muscle around a joint will recover sufficiently to be a strong factor towards the development of deformity, but being alone, or at the most having one adjacent muscle acting, it is impossible to make use of that power for the good of the patient. In other words, that muscle is a good deal more worry than it is worth. In such a case we may be driven to throwing the muscle out of action altogether by excision of a large piece of its tendon. The only other alternative is to transplant the tendon to a position where its power will be

harmless even if not particularly useful. As an example we may take the case of the biceps femoris surrounded by paralysed muscles and causing the triple deformity of flexion, valgum, and external rotation at the knee-joint. The tendon may be transferred to the front of the joint to take the place of the quadriceps, but I have yet to see the case where it has become an efficient extensor of the knee.

As already stated, operative treatment during the second stage should be confined to the correction of deformities; they are bound to get worse if untreated, and so long as they are present, muscles which may have a potential power of recovery are being ruined by overstretching.

The operative procedures are practically limited to tenotomies, fasciotomies, wrenching and tendon lengthenings. The latter is preferable in the bigger tendons; in the tendo Achillis, for instance, the Z method should be employed, and it matters little whether this is done by the open or the subcutaneous procedure. Sufficient lengthening of the tendon will be obtained, without undue elongation and resulting loss of power, if the tendon is allowed to unite with the foot at a right angle. I prefer the open method, particularly when the recovery is fairly evenly distributed in the muscles below the knee; it is more accurate, and the ends of the tendon can be sutured so as just to allow the foot to be brought to the right angle before the calf muscles are pulled on. The foot should then be dropped a little and held in this position for a few days, then gradually brought to a right angle and kept there. Walking should not be permitted for six weeks.

Having corrected deformities, the parts should be retained in the over-corrected position so as to relax as much as possible the weak muscles and stretch the strong, while re-education, massage, etc., are carried on vigorously.

Genu Valgum.

A not uncommon deformity at the knee, already referred to, due to the pull of the biceps muscle which has alone recovered, or has recovered to a greater extent than the rest of the muscles about the joint, is a triple one—a combination of genu valgum, flexion of the knee, and external rotation of the fibia. The biceps may or may not require lengthening, but in all cases correction must be gradual. I have found a jointed apparatus in which by means of a key the relative position of the two halves of the splint can be altered, of great service. Plaster is applied to the thigh and leg, the apparatus is adjusted to the same angle as the deformity, applied to the plaster, and more plaster bandages added to fix the thigh and leg pieces respectively. By means of the key daily improvement in the position of the joint can be brought about. Osteotomy is not required.

Splints.

For the foot I like a "tin shoe" which is made specially to meet the requirements of the particular deformity present. If the tendency is towards equino-varus, for instance, the sole plate should be above the right angle, should be everted, and should be curved, concave outwards, so that the foot when fixed to it will be in a position of calcaneo-valgus, with the fore part of the foot abducted. A quadrant and screw with a hinge at the ankle may be added when full correction is impossible at first, so that alterations in the splint may be made as the patient improves.

For the knee either a tin shoe with the calf-piece carried up to the buttock or a celluloid splint may be used.

In the hip we usually have to contend against flexion deformity; it is best dealt with by making the child sleep on a double inclined plane bed. This is easily made by putting a firm bolster crosswise beneath the centre of the mattress. Towels and sandbags to keep the knees down will ensure a hyperextended position of the hip joints, provided these joints are kept at the highest point of the bed. Jones points out that some internal rotation is necessary to ensure stretching of all tissues. If full extension of the joint is impossible, a sandbag may be placed across the lower end of the femur for an hour or two twice a day, while ordinary weight extension is applied to the leg.

For the arm the particular splint used must depend on the distribution of the paralysis, but in many cases the bithy palsy splint shown or some modification of it will be found suitable.

For difficult cases, or where economy is necessary, although adequate supervision is available, removable

plaster-of-Paris shoes or other splints are useful. Celluloid, which was introduced in the treatment of these cases by the late Dr. Batten,¹⁰ is excellent for some cases, but I think there has been a tendency to use it in unsuitable cases. As usually made for the legs, celluloid splints are most inefficient as holders of the foot and preventers of deformity, though they answer admirably in cases of paralysis about the knee-joint. Personally I use them only in severe cases—that is, where the whole limb is paralysed more or less completely, and where the tendency to deformity of the foot must of necessity be comparatively weak. Experience teaches me that one or two points should be mentioned. Complete correction of deformity is essential before the use of these splints. It is not uncommon to see a celluloid splint made to fit a knee with a definite genu valgum. Secondly, in taking the model, plaster bandages must be carried right up to the top of the thigh or even further, and right to the tip of the toes; it is not uncommon to see the splint reaching only two thirds of the way up the thigh and ending behind the ball of the foot. Thirdly, the foot must be at a right angle, and kept in this position during the whole of the period of the taking of the cast.

It is impossible to describe in detail walking apparatus for use by day, but a few points may be mentioned. One question that arises in every case with a tendency to drop-foot is whether a toe elevating spring should be used or only a right angle "back-stop," which means that the joint opposite the ankle is so constructed that dorsiflexion is free, but plantar flexion cannot proceed beyond a right angle. I am inclined to favour the latter, for a spring is either so strong that the calf muscles cannot overcome it at all, and the patient walks on the heel, or the calf muscles are made unduly strong by having to overcome the pull of the spring. This is an undesirable result, as it is equilibrium between the opposing groups of muscles that we are so anxious to obtain.

In paralysis of the glutei muscles it is necessary to have an accumulator acting behind the hip-joint of the iron, to replace the paralysed muscles and retain the patient in an erect position. To get a firm attachment for the accumulator it is necessary to have a celluloid spinal jacket made, and it is also an advantage to have celluloid sheathing pieces for the thighs riveted to the "irons." The jacket can be cut away freely in front and be little more than a back plate, provided that there is no scoliosis.

THIRD STAGE.

We now have to consider the various problems which confront us when further recovery of muscle power is impossible.

Tendon Transplantation.

Orthopaedic surgeons are fairly well agreed upon the general principles which should govern the surgeon in carrying out tendon transplantation. An operation of this description should never be done until at least two years have elapsed since the onset of the disease, and never till any deformity present has been fully over-corrected. To shift a tendon and expect its muscle to correct deformity is bound to lead to disappointment. What we hope to achieve by tendon transplantation is to restore or increase the power of movement in a certain direction, to give stability to the part, and to check a tendency to deformity, and thus to make possible a reduction in the amount of apparatus worn by the patient. Sir Robert Jones,¹¹ to whom one naturally turns for help in this as in every branch of orthopaedic work, has insisted on the importance of selecting for transplantation tendons of which the muscles have shown definite evidence of very considerable recovery. Transplantation of a muscle which is only just acting is worse than useless.

The transplanted tendon should always be attached subperiosteally or even in a tunnel in the bone whenever this is possible, rather than simply sewn to another tendon. It is not advisable as a rule to shift the attachment of a tendon half way round the circumference of a limb; particularly is this so when the muscle has a pure action. For instance, good results are not usually obtained by trying to make a pure flexor into an extensor. An operation commonly practised is that of shifting the biceps femoris tendon and inserting it into the patella. I am open to conviction, but I have still to see such a shifted biceps contract alone at will, and produce extension of the

knee-joint. I have seen it contract with the flexors and interfere with the action of its fellows, but this is a very different thing from this muscle producing extension of the knee-joint at the will of the patient. On the other hand, the tibialis anticus is a dorsiflexor of the foot as well as an inverter, and when shifted to the outer side of the foot still acts as a dorsiflexor, and comes into action as such at the will of the patient, but its new attachment makes it combine dorsiflexion with eversion instead of inversion. In such a transplantation we do not rely on re-education of higher centres; hence the success which follows such an operation.

One of the most satisfactory transplantations is insertion of the extensor longus hallucis tendon into the head of the first metatarsal for those cases with a tendency for the ball of the big toe to drop, and for the big and other toes to cock up in the hammer position; more or less valgus is a common accompaniment; the tibialis anticus is usually paralysed, though not always. The line of action of the transplanted tendon is not appreciably altered, and being meant for an elevator of the fore part of the foot, it achieves this object with ease. There is one small addition to the operation as usually performed that I have found useful. The operation is followed by flexion of the terminal phalanx of the big toe, a condition which may be distinctly annoying to the patient, particularly when putting the foot into a boot. To avoid this, I sew the distal cut end of the extensor proprius tendon to the slip from the extensor brevis to the big toe, the terminal joint of the big toe being fully extended. The distal portion of this tendon now acts as a ligament, and prevents the dropping of the terminal phalanx.

Transplantations for paralysis of the upper limb are much less commonly performed. The war provided us with a useful experience in transplantations about the wrist-joint. In the forearm we have a very different problem from that encountered in the foot. In the hand and wrist deliberate, exact, and even fine movements are necessary, whereas in the foot mere stability is necessary, together with the gross movements of dorsiflexion and plantar flexion of the foot. Fortunately the synergic action of muscles about the wrist enables us to select tendons for transplantation which are normally called into action by forced contraction of the muscles which have become paralysed and which we wish to replace; as a result, anything in the way of re-education of higher centres, if this be possible at all, is not required. If the dressings are removed three weeks after operation, the desired movements of the fingers and the thumb can be performed readily, and with suitable treatment these movements rapidly become brisk and strong. Such a result unfortunately is not invariable, and for two reasons: either the muscles selected for operation are not the best, owing to an error of judgement on the part of the surgeon, or because the paralysis has limited the choice, or the technique of the operation is imperfect, the error usually being on the side of laxity of the transplanted and paralysed tendons.

This brings us to the important point of the strain that should be put on a transplanted tendon before it is attached to a bone or other tendon. There are two schools of thought on this subject: one says that the tension of the transplanted muscle should be no more than the normal tension of that muscle when the joint upon which it normally actuates is in the neutral position; whereas the other school says that the graft should be carried out with the tendons as tight as possible. When operating for the relief of peripheral nerve injuries, in which cases the muscles selected for transplantation are healthy, and have as a rule never been paralysed, there is no question that tightness of the tendons at the moment when the sutures are being inserted can alone give satisfactory results. In poliomyelitis, however, the problem is not quite the same; the muscle selected for grafting has almost certainly been paralysed at some time previously, and cannot therefore be expected to stand stretching in the way that a healthy adult muscle can. However, I am now transplanting tendons in cases of poliomyelitis with a much greater strain upon them than I did before the war, and I am convinced that the results are thereby improved.

One more point must be referred to, and that is the necessity for protecting the grafted muscle from undue strain for several months after the operation. This is

particularly necessary in the foot, where body weight and gravity play such important parts in the production of deformity. Exercises to develop power in the transplanted muscles should, of course, be carried out after sufficient time has elapsed for firm union of the transplanted tendon to occur at its new insertion.

ARTHRODESIS.

Arthrodesis should never be performed before about nine years of age, and gives better results if even further delayed.

In the shoulder there are two necessary conditions—fair power in the muscles fixing and moving the scapula, and sufficient recovery in the forearm and hand to warrant the operation. The elbow may be kept at a right angle by removal of skin from the front of it.

Arthrodesis of the hip-joint for poliomyelitis seems to me to be very rarely justifiable. The same may be said of the knee-joint. The chance of breaking the leg with the bones imperfectly developed, as they must be in a grossly paralysed limb, must be great; moreover, I think it only fair that the patient should be left to judge for himself whether he would sooner wear apparatus for the rest of his life and be able to bend his knee to sit down, or whether he would prefer a rigid straight leg.

In the ankle arthrodesis gives an excellent result in some cases, but not in all; the result apparently depends on the stability of the subastragaloid and other joints of the foot. If the mid-tarsal joint (Jones)¹² or the subastragaloid joints are fixed in addition, the results are much improved. Whitman's¹³ operation, which involves removal of the astragalus and shifting backwards of the foot so that the tibio-fibular mortice embraces the anterior end of the os calcis, gives excellent results in those almost completely paralysed legs. This is a particularly useful operation when calcaneus or calcaneo-valgus is present and tendon transplantation is impracticable or is considered insufficient by itself. The peronei, if acting, should be attached to the os calcis or tendo Achillis, as practised by Whitman.

The results of the insertion of silk to act as ligaments are, I think it may be fairly stated, very uncertain, and the improvement cannot be relied upon to last. As in every branch of surgery, particularly orthopaedic surgery, those who are keenest on, and employ to the greatest extent, a particular method of treatment are those who will get the best results therefrom; but my own experience of this method is that it cannot be relied upon to prevent a relapse of the deformity. The same may be said of tendon fixation, though I am not prepared to deny that both these methods may be of use when combined with tendon transplantation in selected cases. If a hole is bored through an atrophic bone—the tibia, for instance—and through it is passed a strand of silk, the opposite end of which is attached to a bone in the foot and the thread tightened, the weight of the foot, with or without the assistance of the calf muscles, will cause gradual absorption of the hole in the bone under the constant pressure of the silk, so that sooner or later the tightness of the thread eases off and the foot is no longer held in the desired position.

As regards the spine, poliomyelitis provides us with some of the most difficult cases to treat. As Lovett¹⁴ has pointed out, the deformity can begin while the patient is still in bed. In such cases I have found it advisable to use corrective slings pulling horizontally in opposite directions, made of towels or broad strips of flannel and tied to the sides of the bed. In the usual child's cot it is possible to apply these slings without compressing the chest and the abdomen by attaching the two ends of a sling to the upper and lower bars of the side rails respectively.

Tilting of the pelvis may be corrected by a perineal band pulling obliquely upwards on one side, while a weight extension on one leg pulls downwards on the other. Later a plaster bed, moulded to the patient in the slightly over-corrected position, if this position is possible, may be used for sleeping or resting in; while if walking is possible a celluloid jacket, holding the spine in the over-corrected position, may be used. Correction can also gradually be achieved by the use of a plaster bed with pieces of broad webbing stretched across so as to bring pressure to bear on certain spots—for example, the prominent ribs on the convex side of a curve, as first suggested, I believe, by Mr. Openshaw.¹⁵ I prefer to use felt pads in the floor of the bed to serve the same purpose.

In recent years, with the increase of bone grafting, particularly as the result of the pioneer work of Albee, grafts and other methods of bony fixation have been employed for the fixation and prevention of deformity of the spine in these cases. Unquestionably this is a justifiable procedure in selected cases, but many cases are not severe enough, while others are so severe and intractable, or are so hopelessly crippled generally, that the operation is unjustifiable. A case with obliquity of the pelvis and lumbar curve due to paralysis of the psoas or abdominal and lumbar muscles on one side, seems to me one in which operative fixation of the spine is worthy of serious consideration in the absence of any contraindications. Again, some severe "C" curves which are seen before fixation of the deformity to any great extent has occurred should also be treated by gradual correction as far as possible, with a view to eventual fixation by a bone graft. More is being done along these lines in America than in this country, by Albee¹⁶ and Mackenzie Forbes¹⁷ among others.

MITRAL STENOSIS, AURICULAR FIBRILLATION, AND THE ACTION OF DIGITALIS.

BY

C. H. CATTLE, M.D., F.R.C.P. LOND.,

HONORARY CONSULTING PHYSICIAN, NOTTINGHAM GENERAL HOSPITAL.

A WRITER in this JOURNAL[†] recently made the statement: "A clear conception of auricular fibrillation is essential to the management of heart disease." The commonest antecedents of this disorder are mitral stenosis and myocardial degeneration; it also occurs in connexion with arteriosclerosis, aortic and mitral incompetence, and certain acute diseases, as rheumatic fever, pneumonia, diphtheria, and infective endocarditis.

Whatever the cause of the fibrillation it can be most profitably studied in relation with mitral stenosis. If we wish to understand mitral stenosis, as we commonly see it in young adults, we must go back to the rheumatic heart affections of childhood. Our conceptions of rheumatism are apt to be dominated by the occurrence of arthritis. In adults arthritis is the prominent symptom; the heart affection is incidental. In children, on the other hand, the joint signs are often transient, insignificant, or absent, while carditis is very common. I use the word "carditis" advisedly, because pericarditis and endocarditis never occur without myocarditis. It is in children especially that this liability to pan-carditis exists. Murmurs and friction are well known and common signs, but the most striking sign of all, to my mind, indicating involvement of the myocardium, is the accelerated cardiac action which may continue for weeks or months following an attack of rheumatic fever or chorea. These cases need prolonged rest if the cardiac condition is to have time to quiet down. Valvular and muscular lesions are incurable, and the only chance of averting or mitigating their effects is to encourage resolution of the infective process by means of rest.

The structure of the rheumatic nodules on the valves and in the wall of the heart is similar to that of the subcutaneous fibrous nodules occasionally met with. The effect of the nodules on the valves may be rapidly destructive, causing, in the case of the mitral, more or less regurgitation; these cases may end in mitral stenosis from subsequent contraction of the fibrous ring to which the valve segments are attached. But a more common origin of stenosis is the presence in the valve of islets of infection, which lead to a chronic process of sclerosis extending over

years. Rheumatism is proverbially relapsing, and knowing its nature we can have no doubt that from time to time extensions of the infection in the heart take place, not necessarily accompanied by arthritis, but gradually leading to a tighter and tighter narrowing of the mitral orifice. Mitral stenosis is commoner in women than in men; chorea is commoner in girls than in boys. Acute observers like Barlow have suggested that the partiality of chorea for the female sex may to some extent explain the frequency of mitral stenosis in women. Chorea, like rheumatism, is notoriously apt to relapse; sometimes a murmur can be heard during an attack, sometimes not. I believe that most, if not all, cases of mitral stenosis are due to sclerosing valvulitis, whether choreic, rheumatic, or merely latent; its destructive effects are slow and insidious; the mitral curtains become thickened, indurated, and adherent at their margins, and it is not realized till years have elapsed that an irremediable narrowing has occurred. This sclerosing process may cause no alteration of the heart sounds till it has been at work a considerable time.

The symptoms and signs of mitral stenosis may be divided into (1) the incipient stage; (2) the stage of full development; (3) the stage of auricular fibrillation. In the first two stages the pulse is regular; in the last it is grossly irregular.

Mitral Stenosis: Early Signs.

The first stage causes no symptoms, hence it will not be recognized unless looked for. Children of known rheumatic history ought to have their hearts examined from time to time, especially at the time of choosing a career. Every patient ought to be examined both in the standing and the recumbent position; a presystolic murmur, not heard in the standing position, will sometimes be brought out if the patient does a little exercise and then lies down. An important early sign is an apparent reduplication of the second sound at the apex. It is not a true reduplication, as the second part of the sound is produced at the mitral and not at the semilunar valves. A real reduplication, heard at the base, is due to asynchronous closure of the sigmoid valves, but is of no importance as an early sign. An apparent doubling of the first sound at the apex may be due to a short and ill-developed presystolic murmur. An instructive case of this kind lately came before our special neurological board for army pensioners:

He was a man, aged 25, who complained of muscular pains and occasional swelling of the ankle-joints. I noticed slight, irregular, jerky movements of the right arm and leg, but as these were common in this class of case, he did not at first occur to me. In positions the heart's impulse was here was no obvious enlargement; the first sound was rather loud and accompanied by a systolic murmur; the second sound at the apex was reduplicated. At this moment one of my colleagues happened to come into the room and I asked him to confirm the signs. While he was listening he exclaimed: "Why, the man's got chorea!" and so he had plainly enough.

Here we had the three parts of the rheumatic picture pieced together—namely, the muscular and arthritic pains, the heart lesion, and the chorea. These early signs indicate heart disease of at least three years' standing, and the fully developed signs of mitral stenosis indicate disease of five or more years' standing. This man was working as a coal-miner, and illustrates the point of unsuitability of occupation. He was advised first to have treatment from his insurance doctor, and then to change his occupation if possible.

Intermediate and Later Signs.

The fully developed signs of mitral stenosis are so well known that I need only refer briefly to them. A presystolic thrill felt at the apex and terminating with the impulse is almost pathognomonic. The rough presystolic murmur of crescendo character, terminating in a short snapping first sound, and the accentuated pulmonary sound are well known and typical signs. It must be remembered that the murmur is heard over a very limited area—that is, the immediate neighbourhood of the apex; neglect of this fact has sometimes led to failure in diagnosis. The short first sound resembles the second sound in quality, and as the second sound often cannot be heard at the apex care must be taken not to mistake the presystolic murmur for a systolic one, and the first sound for the second. This mistake can be avoided by timing the

[†] A paper read before the Nottingham Medico-Chirurgical Society, February 16th, 1921.

¹ Review of *The Mechanism and Graphic Registration of the Heart-beat*. By Dr. T. Lewis. Vol. ii, 1920, p. 166.

murmur with the finger on the carotid pulse. The peculiar sharp first sound can often be heard several inches, even a foot or more, from the patient without the intervention of a stethoscope. The presystolic murmur may totally disappear, but the snap sound will probably remain. I went into the country lately to see a woman, aged 38, whom I had known for years as having a well-marked presystolic murmur. On this occasion the heart was regular and slightly rapid; there was neither murmur nor thrill, but the snap sound was definite and audible without contact with the patient at a distance of two inches. As the left auricle becomes dilated and hypertrophied and the stenosis narrower, the murmur often occupies the whole of the diastole, commencing with an accent shortly after the second sound, then diminishing, and again intensifying in the presystolic period. After auricular fibrillation has set in the diastolic portion of the murmur remains and the presystolic disappears.

This stage may last a varying number of years, the condition may appear to be stationary, and some people would say the valvular lesion was compensated. If the stenosis remain moderate life may be prolonged many years, but the tendency is for the narrowing to increase and for breakdown of one kind or another to occur. A large proportion of persons with mitral stenosis seldom feel well: they are soon fatigued and out of breath; there is generally slight cyanosis; they complain of cold extremities because the warming blood cannot reach these parts in sufficient quantity; they suffer from occasional epistaxis, from bronchitis, dyspepsia, and passive congestion of the viscera. My object is to follow out the effect of mitral stenosis on the heart, and only passing mention can be made of such accidental complications as haemoptysis, infarction of the lungs, embolism of cerebral or other arteries.

Auricular Fibrillation.

In a case of mitral stenosis the auricles may assume a condition of fibrillation in consequence of the natural progress of the disease, or of some sudden violent effort. The auricles have now lost the function of contraction by which they normally drive the blood into the ventricles. By fibrillation is meant an inco-ordinated, tremulous and flickering movement of the muscular wall of the auricles, which is in a state of continual agitation. If I may use an illustration of my own, I should compare the fibrillating auricles to the weak fibrillary twitchings which occur in the muscles of the body when they are undergoing paralysis and atrophy. In both cases weak and isolated contractions are taking place, and in neither case is there any resulting, purposive movement. The ventricles normally receive their contractile impulse from the auricles by means of the auriculo-ventricular bundle of fibres; the weak, rapid and irregular impulses arising in the auricles are reflected in the weak, rapid and irregular pulse—the well-known mitral pulse. This has been called “the perpetually irregular pulse,” since it remains irregular as long as the auricles continue to fibrillate. Most other forms of irregularity (for example, that due to premature beats) are either temporary or alternate with periods in which the pulse is regular. The fibrillations of the auricles may amount to as many as 500 a minute; the ventricular rate may be 120, 140, or even 200 in rare cases, so that it is obvious that many of the impulses fail to excite any ventricular contraction. It would not be correct to describe this condition as one of paralysis of the auricles. Indeed, if the auricles were paralysed and merely passive the heart would be better able to carry on its work. The ventricles are worried by the ceaseless stream of weak, rapid and irregular impulses proceeding from the auricles; their contractions are consequently irregular and inefficient, and their period of repose is shortened. This irregular action, combined with structural changes in the muscular wall, is a common cause of heart failure, as we see it manifested by dilatation of the heart, venous engorgement, passive congestion, and oedema. Many of the weak heart-beats cannot be felt by the finger on the pulse, and the only method of correctly ascertaining the real ventricular rate is by auscultation. This rule of auscultation applies to all forms of pulse irregularity, which by this means can often be differentiated from one another. The perpetually irregular pulse is in itself an important sign of auricular fibrillation, but there are also other signs in mitral stenosis

cases. The murmur loses its rasping character, becoming softer; it is often purely diastolic, not running up to the first sound when the pauses between the beats are long, but occupying the whole interval when the pauses are short. This diastolic murmur has been mistaken by competent observers for the murmur of aortic incompetence; Mackenzie, to whom we owe the foundation of our modern knowledge of heart disease, was the first to explain the true meaning of the murmur. The first sound often loses its sharp snap and becomes more of a tapping character. The onset of auricular fibrillation may in some cases cause but little discomfort; in others it may give rise to increasing cardiac failure from the first. Sir James Mackenzie states that he has seen many individuals with auricular fibrillation who have led strenuous lives, engaged in hard manual labour, and infers that in them the muscle of the ventricles had not been seriously damaged.

I have stated that in auricular fibrillation the ventricles beat rapidly and irregularly. This is true for the great majority of cases. Occasionally the contractions are slow and regular; this occurs when myocardial disease involves the auriculo-ventricular bundle, causing heart block, and thus interrupting the passage of impulses from auricle to ventricle.

Proof of the Occurrence of Auricular Fibrillation.

Mackenzie has said that “the discovery of this disorder is the most important yet made in the functional pathology of the heart.” Of the many hypotheses put forward to explain the perpetually irregular mitral pulse this is the only clear and unassailable interpretation. After Mackenzie had been engaged for some years in studying tracings from the venous pulse in the neck he noticed fine fibrillary waves in the tracing in certain cases where the wave caused by normal auricular contraction was absent. It is now known that these fine waves are caused by the fibrillating auricles. Dr. Thomas Lewis was the first to demonstrate the occurrence of fibrillation by pointing out the similarity between clinical electro cardiograms, and similar records taken from animals in which fibrillation had been experimentally induced. Spontaneous fibrillation sometimes occurs in horses, and it was from observation on a horse that Dr. Lewis obtained final proof of the occurrence of this disorder. The animal was rendered unconscious, and in the exposed heart the fibrillating movements were clearly seen. It is thus obvious that the conception of fibrillation is no mere theory devised to explain the irregularity; but that the actual occurrence of this disorder has been definitely proved both by observation and experiment.

The Action of Digitalis.

It has long been known that digitalis slows the heart by prolonging diastole—that is, increasing the resting period. It is the discovery of fibrillation that gives the clue to the reason why digitalis acts so remarkably in some cases, and in others appears to fail. It has a twofold action, slowing the whole heart by stimulating the vagus nerve, and, by a specific influence on the auriculo-ventricular bundle, blocking some of the impulses proceeding from auricles to ventricles. It is thus clear why in many cases where the rhythm is normal and regular but little good results from digitalis, and that a great deal of the benefit derived in auricular fibrillation is due to the blocking of many of the disorderly impulses proceeding from the auricles. In this affection the heart is more susceptible to its influence, and there are times when it acts like a specific. It is more successful in rheumatic than in degenerative cases. Many cases of mitral stenosis, when the pulse is regular, do not require digitalis and are better without it. It should, however, be used whenever there is dilatation, except in acute febrile conditions. After irregularity has set in, whether in the early stages, or in the later ones characterized by oedema and other signs of heart failure, the results are often brilliant.

There are many ways of giving digitalis, but for ordinary purposes the B.P. tincture is reliable. It is said to lose its potency when dispensed with water, but I have not found this to be a common occurrence. In auricular fibrillation one drachm of the tincture—that is, rx every four hours, or mxxv every six hours—should be given daily, carefully watching the effect by counting the pulse twice a day by auscultation. After four or five days the heart's rate will begin to fall; in another day or two it will be

between 70 and 80, and then the drug must be left off for a few days. When the heart's beats occur in couples, as is sometimes the case, the drug should be immediately omitted for a few days. Other signs of sufficiency are severe headache, nausea, vomiting, and diarrhoea. Any of these call for suspension of the drug. After a physiological reaction of this description has been obtained, an attempt should be made to find the daily quantity of digitalis which will keep the heart about the normal rate. Patients can take small tonic doses for months without bad effect if they are instructed to omit the medicine for a few days occasionally. The patient's sensations are a good guide as to whether more or less of the drug is required, and some feel best when the heart's rate is kept as low as 50.

In heart failure from purely degenerative changes, in which the pulse frequently remains quite regular, the effects of digitalis are not so good. In these conditions digitalis should be given in the same doses with the same precautions as I have already advised. Mackenzie states^{*} that he has many times attempted to reduce the increased rate of the heart when the rhythm was normal, and invariably failed. This observation certainly applies to all febrile and toxic states. Here the heart muscle is poisoned by the bacillary or other toxin, and digitalis can have no good effect while this condition remains. It may be useful for the resulting heart weakness after elimination of the toxin. Sutherland† obtained reduction of the pulse rate after the temperature had subsided in rheumatic fever. Speaking generally, more good may be anticipated when digitalis slows the heart's action; a longer period of repose is followed by a stronger beat. Cases have been reported in which good resulted although no reduction in rate was obtained.

For pulse irregularities due to premature beats, which commonly cause intermission of the pulse, digitalis should not be given. The drug itself will occasion premature beats, and would certainly aggravate the condition where the tendency already exists. It is not a safe conclusion that because a heart intermits occasionally it is necessarily a weak heart. Digitalis is often wrongly given for supposed "weak heart." Our ideas are certainly clearer than they were ten years ago as to the cases digitalis is likely to relieve and those which it is not.

The paper was illustrated by lantern slides. For some of the subjects I am indebted to Sir James Mackenzie, Dr. Lewis, Dr. Price, and Messrs. Shaw and Sons.

THE TREATMENT OF SCIATICA BY GALVANIC ACUPUNCTURE.

BY

E. A. GOULDEN, M.D.,
 LLANDRINDOD WELLS.

THE treatment of sciatica may be comparatively simple or very troublesome. Some mild cases, with rest in bed and sedatives, recover, but in others the whole Pharmacopoeia has no effect, for no known drug has any effect on neuritis or on the absorption of the exudation. Neuritis is usually divided into two types—the parenchymatous and interstitial—no local treatment can have any effect on the former; it is with the interstitial type associated with inflammatory changes in the sheath and connective tissue, and accompanied by exudation of cells, that we are concerned. There is reason for believing that this exudation is distributed not continuously along a nerve but in patches revealed by tender areas or by use of the faradic current. Treatment by acupuncture is particularly serviceable in these cases of nodular fibrositis.

Dr. Davis, formerly of Llandrindod Wells, first introduced and described this method in the *Bristol Medico-Chirurgical Journal* in June 1915, but it has been in use for twenty years in hundreds of cases of sciatica and other forms of neuritis.

It is not my intention here to enumerate the different causes of sciatica. I exclude all cases due to pelvic growth, bone disease, spinal cord disease (as locomotor ataxia), diabetes, venereal disease, etc. These have their own special form of treatment, and must be managed on constitutional lines. A definite diagnosis is as important in the treatment of sciatica as in any other ailment, for local treatment of sciatica when there is grave constitutional disturbance is bound to end in failure.

The aim of all the various forms of treatment devised for sciatica is to induce hyperaemia of the nerve. In the Scotch douche and radiant heat an endeavour is made to secure this by the varying stimuli of hot and cold water, or by exposing the whole limb to high temperature. A general hyperaemia of the skin and underlying tissues of the whole of the lower extremity may be obtained, but there is no guarantee that the nerve shares in this hyperaemia—often it does not; at any rate the method is empirical.

By acupuncture the hyperaemia occurs just where it is required, and it can be given in definite doses varying according to the response of the nerve. Again, when an electric current is passed through the tissues sodium hydrate is formed at the negative electrode, which in this case is the needle passed down to the tender spot on the nerve. This sodium hydrate has a caustic action on the tissues. In acupuncture only a small amount of current is used (3 to 6 milliamperes) whereas in destruction of a naevus 20 milliamperes or more are used. In the case of the naevus a large area has to be destroyed, but in the case of exudation in the nerve sheath the area is very small and the effect should be limited to the exudation. The effect of ionic movement in the tissues is involved also.

From one or all of the above effects it is maintained that by this treatment there is complete relief of pain, but the wasting of muscles with weakness of limb and lameness requires appropriate treatment.

Electrical acupuncture, if carried out according to instructions, is harmless. It must not, of course, be used recklessly with any strength of current, nor must the needle be plunged into any part of the body without consideration of the underlying parts.

Method of Application.

The equipment necessary is:

1. Pantostat or other universal apparatus.
2. Insulated needles of various lengths with platinized points.
3. Holder for needles.
4. Button electrode.
5. Hypodermic syringe and 2 per cent. solution of novocain.
6. Sterilizer.

The sensitive spots along the course of the nerve must be found by means of the faradic current and each one separately treated. An indifferent electrode attached to the positive pole of the faradic current is placed below the knee or on the back. The negative pole is attached to a moistened wash-leather button electrode mounted on a handle.

The buttock is first tested; after turning on the current until the patient just feels it, the button is moved over the surface of the skin until a sensitive spot is touched; this is marked. Two or more of these spots may be found, and the most sensitive is first treated. The easiest way to find the most painful spot is to reduce the current until one or other of the spots is not felt. In neurotic cases it is a good plan to approach the spots from different areas to be quite sure it is properly localized.

The galvanic current is now used. An insulated needle, about 4 in. long, sterilized and attached to a holder, is connected up to the negative pole. The same indifferent electrode is used, now transferred to galvanic current instead of faradic. The skin over the area is painted with iodine and anaesthetized with novocain (2 per cent.). The needle is applied to the chosen spot and the current quietly turned on. I usually begin with about 2 milliamperes. The needle is now passed through the skin and deeper tissues and more current applied. It is necessary for the patient to feel something, but it is unnecessary to produce pain. Good results can be obtained in some cases by using 2 milliamperes; in other cases 5 or 6 milliamperes may be required. If the patient complains of pain, then the strength

* BRITISH MEDICAL JOURNAL, JANUARY 23rd, 1921, p. 152.

† Ibid., vol. ii, 1919, p. 50.

of current must be reduced. A reliable guide as to when the needle is in the right place is that the patient states that he experiences the same kind of pain as that of which he complains; the position is then correct and the treatment continued for ten minutes. If not found at first, then the needle must be moved about under the skin until it is. During this ten minutes it may be necessary to increase or diminish the current according to the patient's sensations. After the current has been passing a few minutes the pain often diminishes and the current can be increased. After ten minutes the current is slowly turned off, the needle removed, and the puncture sealed with collodion. No after-treatment is necessary. The spots are treated on alternate days.

It is not possible to say beforehand what strength of current may be required, but the treatment should not be painful. If too much current is used, then considerable pain may be produced and a great deal of reaction follow; the more tender the spot, the less the current. The nerves in different parts of the body vary considerably in the amount of current they take; thus, the nerves of the scalp readily take up to 5 or 6 milliamperes and the sciatic and its branches are nearly as tolerant.

The number of spots to be treated in any given case of sciatica varies. There may be only one or two or there may be as many as seven, eight, or nine. The average is about five, but no case must be considered cured until every spot has been treated. This must be done systematically, beginning with the buttock and

following down the thigh, front or back, according to the distribution of the pain. Pain around the knee-joint is often troublesome, and spots for this are found about 3 or 4 inches above the patella on one or both sides of the quadriceps extensor tendon. For the pain below the knee, spots are sought for in the calf or front of the leg, also in the latter area for sensory disturbances over the dorsum of the foot.

Acupuncture will not cure the wasting that frequently accompanies long-standing sciatica, and it is important to warn patients of this. The treatment is introduced solely for the relief of pain. For the lameness, and wasting of muscles, the patient must be taught to walk correctly, and massage and electricity are used.

All the failures I have had have been in cases of very long standing in which probably the exudation has become organized or the nerve has been damaged by pressure beyond recovery. It is not possible to recognize these cases beforehand, for many cases of very long standing recover; one case I recall was that of a man of 50, who obtained complete relief of pain, although the nerve was so damaged that his patellar reflex on that side was absent.

The line of treatment described is applicable to any other accessible nerve with suitable modifications. The sciatic nerve is taken as an illustration only; equally successful results can be obtained in any other part of the body.

LIGHT METAL LIMBS IN ABOVE-KNEE AMPUTATIONS.

BY

EDRED M. CORNER, M.Ch., F.R.C.S.,

MAJOR R.A.M.C.(T.F.).

SURGEON TO ST. THOMAS'S HOSPITAL; CONSULTING SURGEON, QUEEN MARY'S AUXILIARY HOSPITAL, ROEHAMPTON.

The wooden walls of Old England in their day did excellent service; they were replaced by metal because of its greater efficiency. So it will be with wooden limbs; they will only exist for particular purposes. Among artificial arms that made of duralumin for lightness more than holds its own. For amputations of the thigh above the

FIG. 1.—With the amputation at 1 there is little bony leverage to help the muscles. With the amputation at 3 there is much bony leverage against the muscles (like a high-gear machine going uphill). With the amputation at 2 the above two factors are more nearly balanced and the patient is best off.

knee lightness of the artificial limb is essential, for the muscles of the stump are parallel with the bone, and the other muscles which activate it, the ilio-psoas and the glutei, are attached to the end of the femur. Hence the longer the thigh stump the greater the leverage against these muscles, and the shorter the thigh stump the less the leverage. The medium length thigh stumps, 8 to 9 in., are best off. This is seen from Fig. 1. Above this point the gluteal group of muscles begin to abduct the bone, making the man walk badly, often with lurching and the circumduction associated with progression on a peg leg (Fig. 2). This comes on progressively as the muscles are strengthened by exercise and after the fitting of the first limb. These are the two chief points in the mechanism of an artificial limb for the thigh

though their capabilities may be great, exhausts them, is wrong. It is not clear whether these conditions result from the degenerative changes which occur in the central nervous system in association with the loss of the educative value of the limb. To remedy this the amputated man requires the lightest limb, a minimum of hospital life, and a rapid return to work and bright surroundings. At present this can only be obtained by the use of a light metal limb with quick fit, quick instruction and after-care. At present all these factors are lacking. Metal is chosen because in light limbs of wood the wood is so thin that it cracks and constant repairs militate against the original cheapness of the limb. A well-made metal limb needs a minimum of repairs, and thereby soon repays the initial outlay.

Owing to assistance given by the Red Cross and Sir Arthur Stanley, and to the kindness of Colonel Sir Lisle Webb and Sir Charles Kenderdine of the Ministry of Pensions, it has been possible to make experiments at St. Thomas's Hospital on these lines, and it is desirable that the results should be made as widely known as possible, since they bear out in practice all that has been prefaced in theory, and offer considerable hope of improvement to 90-95 per cent. of cases of amputation of the thigh. They are based upon observations made on over one hundred light metal limbs. The results of my experiences are shown in the following extracts.

FIG. 2.—As the amputation is done higher and higher up the femur more and more adductors and internal rotators are cut off. The adductors and external rotators are strengthened by the exercise of wearing the artificial limb, and hence its non-fit after a few months' wear. This is more felt by those men of greater mentality. It occurs in the use of both wood and metal limbs and is often shown by the roll of flesh on the inner side of the bucket top.

—leverage and abduction.

At a discussion on the subject of re-education of the limbless, admirably introduced by Mr. Muirhead Little, at the Medical Society in March, 1920, the President, Mr. Warren Low, referred to the mental and moral deteriorations which follow the loss of a limb. These are sometimes great and sometimes small, but almost always present in some degree. The nearer to the trunk the amputation is, the greater would seem to be the change. This change is accentuated by the man's temperament and surroundings, being the greater with the larger mentality. To weight and handicap men who have gone through much with a limb which feels "too heavy" and,

Reports to Sir Arthur Stanley.

The first point to come out was that, although the (metal) artificial limb gave the amputee satisfaction, the metal limb was only a few ounces lighter than specially constructed wooden limbs. The satisfaction could hardly, then, be in the weight. (Light wooden limbs weigh about 5½ lb.; light metal ones 4½ to 5½ lb.) About 90 to 95 per cent. of men suffering from above-knee amputations are greatly benefited by these limbs.

- The universal statement is that they can do more work with a fraction of the fatigue.
- Men supplied with light metal limbs can learn quicker and more than can men with wooden limbs.

- (c) The special light wooden limbs supplied by the Ministry of Pensions are a distinct improvement on the older type, but break and split more quickly, having reached the limits of what wood is capable. The hybrid limb of wood and metal supplied by the Ministry bids fair to be satisfactory. But it is too early to say much about it.
- (d) When conscription was introduced into the army all kinds of men were taken into it and some lost their legs. There is no doubt that men fitted with light metal limbs are happier, more useful men, who more easily learn and amongst whom there is a more generally high percentage of physical fitness than there is amongst the wearers of the wooden limbs. They cannot make C3 men A1 men!

Light metal limbs should not at present be given to all, but those to whom they are *not* given should be carefully selected. At least two refused to exchange their wooden limb for a metal one. At least one who has had a light metal limb prefers his wooden one. (He is stated to have had inadequate length of instruction.) Apparently the heavier wooden limbs are more apt to cause pain and necessitate operations than light metal ones, especially when the fit is imperfect.

Apparently the repairs necessary in metal artificial limbs are less frequent—but more difficult and costly—than they are in wooden limbs. This would be lessened in manufacture on a larger scale and would help to compensate for the larger initial outlay.

It is at present doubtful if there is advantage in having the artificial limb less than 4 to 5 lb. in weight, as the lighter the limb the more uncontrollable it becomes. This is not the theoretical statement it is often said to be.

It should be added that one insufficiently instructed man for urgent reasons was allowed to take away a metal limb in the rough, and it gave him so much trouble that he inquired of the Ministry who was responsible for its repairs. Both man and limb were half fledged.

So much for the theory, the practice, and the immediate results. To ascertain the later results all officers were written to and replies were obtained from a large number. These replies have shown four chief points:

1. Those who had been given and had done well on a heavier wooden limb did most obviously better with metal. They had already shown that they could help themselves, and, supplied with lighter limbs, could do more.
2. A light metal limb should be fitted first of all, so avoiding the delay and learning to use the heavier wooden limb.
3. All men who had previously got about on a heavier wooden limb were for varying times "at sea" with the light metal one before they settled down to steady improvement.
4. The heavier wooden limbs caused far more trouble in painful breaking down and difficult stumps than did light metal ones.

In connexion with 4 it is necessary to say something about the pathology of the stump. The key-note to all the pathology of stumps that are painful and easily break down is the presence of infective inflammation in the tissues. All tissues can be affected. We can see the results in skiagraphs in new-formed bone, and if infective inflammation is found to be present in the bone its presence may be inferred in other structures—nerves, for example. In an amputation nerves must be divided, and being divided they must regenerate. In regenerating it has been shown that they carry down with them the infective inflammation in them, re-infecting and making painful a perhaps merely uneasy stump and producing the late onset of pain. Dr. Urquhart helped much in the bacteriology of these stumps and Colonel Sir Archibald Reid in the skiagraphs. The importance of skiagraphing many stumps that have worn one of the heavier wooden limbs before ordering a second is apparent. Skiagraphy is, in fact one of the most valuable means there is of examining a stump.

In the concluding part of this paper I will quote what three of these officers say for themselves. There are many more replies which show—

1. That at times the light metal limb is badly made and fitted, requiring repairs (even then less so than wood).
2. Light metal limbs are an inestimable boon to many of those who have had thigh amputations.

CASE I.—H

Dis. Work.—The increased ease with which one gets through one's daily work is maintained.

General Condition.—Continues improved.

Athletic Value.—I am markedly able to get about with greater comfort and speed. I have recently been able to take part in boating, fishing, and shooting, all of which entailed considerable activity, and I was pleased with the way in which the light leg responded.

Stiff Ankle.—This slight obstruction is wearing off, and I hardly notice it as a hindrance now. It is preferable to a movable ankle, saves weight, and gives a bit of a spring off the foot.

CASE II.—R.

I am quite delighted with my light metal limb, and am much better in every respect. You will remember how my stump continually broke down with my heavier wooden,* now I can say I have completely got over all that trouble, which has been a constant source of worry to me. I am getting about much better now, and do not know what it is like to be exhausted. This had a great effect on me generally. My health has improved and my work is more of a pleasure and consequently better, and I am hoping to take up tennis again this summer.

In the early days—I mean 1915–16—when the heavier wooden legs were good and well made, I had a comfortable leg, and got on extremely well and was satisfied as far as heavy legs were concerned, but I must say, with my short experience of a light leg, I wish I had gone in for one at first. It would have saved me a tremendous lot. I am quite convinced that light legs are the thing. I could do most things on a wooden one—dance, tennis, climb about rocks, etc., but at what an expense of energy, and I did too much and got overtired.

This officer hits the nail on the head by writing: "The whole secret of the light leg is the conservation of energy, and when one is exhausted one's brain is exhausted as well."

CASE III.—A.

I have had the light metal limb now for over four weeks, and cannot praise it too highly. Candidly, I never before imagined that an artificial limb could be so useful. My first leg was a wooden one, and, in fairness to Messrs —, I liked their limb and its movement, and did very well with it.

As regards distance walking, one evening in London I walked on my wooden leg just over five miles—a good distance on a limb weighing over 92 lb (including shoe), but during the last two miles I was decidedly tired and found my foot scraping the ground very often. With my metal limb I have not tried a long distance walk, but feel sure that this distance could be doubled with less fatigue. A brief outline of my day's work will support this. I walk to the office in the morning (one mile). From 9.30 till 5.30 I am on my feet practically all the time; walk home in the evening, and very often later on I walk again perhaps for two, three, or four miles before bedtime. This does not fatigue me in the very least, and I come home feeling I have enjoyed an outing and could have done miles more.

As regards walking quickly I could do this on my wooden limb, but there was a great strain on the shoulders as the knee was controlled therefrom. The metal one has no shoulder control, and to my mind this is not necessary, as by a slight extra jerk of the stump forward speed can be increased at will. Timing myself in the ward when I had my light metal limb in the rough, I found that I did 136 paces to the minute, which, as infantrymen will know, is a very quick march. Walking uphill with the light leg differs very little from walking on the level. With the heavy leg there is a great difference, and it is very fatiguing and slow work. As regards loss of control in strong wind, in my experience the heavy limb is affected to the same degree as the light, and loss of control varies with length of stump. Personally I have had no trouble and have been in some very strong winds during the last few weeks.

To sum up, I think the light metal limb is far and away superior to the heavy, and I consider myself fortunate in possessing one; and I hope the time will come when I can forget that my heavy limb ever existed.

Light metal limbs having succeeded so well in some 90 to 95 per cent. of thigh amputations it was reasonable to try them on below knee amputations, and this has now been done successfully. The percentage of those improved will be smaller, and it is possible that a better artificial limb may be made for a Syme amputation. It may be to the advantage of the amputated man to have a hybrid limb (wooden socket and metal shin), as tried by the Ministry; at present it is too early to say, but as most serious repairs are required to the sockets it may be doubted if wood should be used there.

* He was sent on from Dover House to St. Thomas's because of this.

At a meeting on April 1st, of the West London Medico-Chirurgical Society, with the President, Dr. F. J. McCann, in the chair, a discussion took place on the diagnosis and treatment of colitis, in which were emphasized the importance of sigmoidoscopic examination, the influence of diet as a cause and in the treatment of the condition, bacteriological examination of the faeces and treatment by vaccines, and the influence of climate. Previous to this discussion a number of clinical cases were shown by Mr. Aslett Baldwin, Mr. B. Sangster Simmonds, Mr. Neil Sinclair, Dr. W. N. Goldsmidt, Dr. Clifford Ellingworth, and Dr. W. R. Marshall.

THE PRESSURE IN THE RENAL, PORTAL AND GLOMERULAR CAPILLARIES OF THE FROG'S KIDNEY.

BY
LEONARD HILL, M.B., F.R.S.

(From the National Institute for Medical Research.)

(Preliminary Note.)

By making an incision through the skin and abdominal wall in the lumbar region of a urethanized frog and removing the ileum on the same side the kidney is exposed. The cautery is used to stop all haemorrhage. A ligature is tied round the membrane attached to the outer edge of the kidney. By very gentle traction the kidney is then drawn on to the transparent peritoneal membrane which covers a small brass chamber with a glass floor, similar to that used by Roy and Graham Brown in their measurement of capillary pressure in the frog's web. A glass cover is then brought down on to the upper surface of the kidney so that it can be squeezed between the membrane and glass cover when air is blown into the chamber. A water manometer indicates the pressure used for compression. The kidney is examined under the microscope, using a magnification of one hundred times. The kidney appears closely covered with a network of branches of the renal portal vein, through which blood flows slowly in copious streams. On compressing with a pressure of about 2 centimetres of water these vessels are squeezed empty, and the tubules and, in successful preparations, the glomeruli then come into view; the arterial blood is seen rapidly circulating through the glomeruli. The Bowman capsules can be seen surrounding some of the glomeruli, and the glomeruli hanging in a clear space within these. In some glomeruli the afferent and efferent vessels are clearly seen, and the blood corpuscles can be watched racing through the afferent vessel, whirling round the twisted capillaries of the glomerulus and out through the efferent vessel. On the inner edge in one preparation a row of glomeruli were seen fed by the branches of one of the renal arteries.

The pressure required to stop the renal artery and the flow in the glomeruli is of the same order as that in the arteries of the web of the frog's foot—for example, when there has been little loss of blood and the circulation is vigorous, 30 to 40 cm. of water. A pressure of 7 to 9 cm. of water in this case sufficed to modify the flow in the glomerular capillaries, making it a little slower. By increasing the compression the corpuscles in the glomeruli could be driven out, the flow reversing through the afferent vessel. In a kidney in which the blood flow had stopped a pressure of 7 cm. of water sufficed to squeeze blood from the larger vessels through the glomeruli and produce a rapid flow. This preparation of the living frog's kidney seems likely to afford a valuable additional means of studying the renal secretion under various conditions.

A CASE OF COMPLETE PNEUMOTHORAX IN AN INFANT, DUE TO PULMONARY TUBERCULOSIS.

BY
GEOFFREY BOURNE, M.D.,

PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN,
SHADWELL.

This case is published for two reasons: First, the condition is extremely uncommon. Secondly, some light is shed as to the probable mode of transmission of the tubercle bacillus to the lungs in childhood in certain cases of pulmonary tuberculosis.

The patient, a boy aged 18 months, was admitted with cyanosis, cough, and dyspnoea, to the wards of the East London Hospital on May 11th, 1920. The history was that he had been in his usual health until three months before, when he contracted measles. Since then he had been in poor health, the chief symptoms being lack of appetite, constipation, wasting, and slight cough. For the last three weeks the cough was decidedly worse; food had frequently been vomited in association with it. The

acuteness of symptoms during this latter period had been distinctly accentuated. He had become bluer during the last few days.

Condition on Examination.

On admission the temperature was 102° F., the pulse rate 142, and the respiration rate 40. The child appeared to be extremely ill. Cyanosis was very marked, being especially obvious in the lips and finger-nails.

Examination of the chest gave the following physical signs: Respiratory movement was slightly diminished on the left side, the intercostal spaces on this side appeared to be fuller. Cardiac movements were visible in the fourth space to the right of the sternum. Cymetric examination showed the left side of the chest to be the larger by a quarter of an inch. By percussion the heart was found to be displaced two inches to the right. The whole of the left side was hyper-resonant. Over the right side the note was less resonant than normal, the impairment was particularly intense at the right base and less so in the right axilla. The respiratory murmur was very much diminished all over the left side, both back and front. Expiration was prolonged over the right lung in front; in the right axilla the breath sounds were bronchovesicular. Numerous fine râles were present over the right lung, back and front, especially at the base. No cardiac murmurs were heard.

The liver and spleen were both easily palpable, otherwise no abnormality was discovered in the abdomen. Clubbing of the fingers was not present.

A condition of complete pneumothorax of the left side, associated with bronchopneumonia of the right lung, was diagnosed.

The temperature fell to 98°, the pulse rate rose to 160, and the respiration rate to 70, within the next twelve hours, and the child died.

Post-mortem Examination.

The child appeared to be well nourished. Cyanosis was extreme; the nails of the hands and feet were light blue in colour. Hypostasis was well marked. The brain was congested, and the subarachnoid in the basal region had a milky appearance; no gross tubercles, however, were seen.

Thorax.—The heart was normal. No pericardial tubercles were found. The left lung was collapsed down upon its root, except at the apex, where it remained adherent to the parietal pleura. The left parietal pleura was studded with miliary tubercles; none were seen on the right side. No excess of pleural fluid was found. The left lung was a solid mass of yellow tubercles. It sank in water. At the apex, where it was adherent to the pleura, a cavity the size of a hazel nut was present. The walls of this were formed by greyish ragged granulation tissue; it was surrounded by an area of extreme caseous change, and its interior communicated by means of a small rent with the left pleural cavity. The right lung was not solid, except in a few small areas. It contained many miliary tubercles. The glands at the hilum of both lungs were slightly enlarged, hyperaemic, but definitely not caseous anywhere.

Abdomen.—No free fluid was present. The liver was seen three inches below the costal margin, and the spleen was also visible. Both were studded with miliary tubercles. Section of the liver showed the presence in its substance of miliary tubercles, some of which were bile-stained. The spleen was adherent to the tender surface of the diaphragm; it, too, had many miliary tubercles within it. Both kidneys showed subcapsular tubercles. A few subperitoneal tubercles were found on the walls of the small intestine. The testes were normal. The parietal peritoneum had escaped except where it came into contact with the hepatic and splenic surfaces.

The right knee-joint was normal.

Bibliography.

Cruchet¹ states that of the causes of pneumothorax in children tuberculosis is the least common. He quotes, in addition to his own experience, Lenz, who found tuberculosis in 40 per cent. of his fourteen cases, and Chyranowski, whose figure is 38 per cent. of twelve cases. He states that in the tuberculous cases tuberculous bronchopneumonia was the commonest cause, but that the opening

into the pleural cavity was very rarely observed. Further that the base of the lung was the commonest site of the lesion.

Boivard² collected 18 cases, 4 of which recovered. Particulars of 12 of these cases are available; 5 were associated with bronchopneumonia, and 4 of these with measles in addition; 2 with miliary tuberculosis; 2 with diphtheria and emphysema; 2 with pulmonary abscess; 1 with trauma.

I have found in the literature no other case of complete pneumothorax due to tuberculosis in a child of 18 months.

Pathology.

The probable course run by the disease in the case under survey is well marked out by the *post-mortem* findings. The oldest tuberculous focus found was the collection of very large mesenteric glands, the most recent was represented by the general miliary tuberculosis. Another point shedding great light on the direction of spread was that the left pleural cavity—the one corresponding to the lesion of the pneumothorax—was studded with miliary tubercles, whereas the right cavity was entirely free from them.

The tuberculous disease of the left apex, although fairly recent, was probably of considerably shorter duration than that present in the mesentery, for no caseation was found in the hilum glands of either lung, and the extent of the apical lesion was less than a square inch.

The following reconstruction of the spread of the disease is here tendered:

The exciting cause of active tuberculosis was the attack of measles, and the primary focus of disease was the mesenteric glands. From this origin tubercle bacilli reached the blood stream by way of the abdominal lymphatics, and were carried through the right side of the heart, eventually reaching among other places the apex of the left lung. Those that reached this position flourished and ultimately produced a rapidly caseating area whose territories spread till the left pleural surface was reached. Adhesions were formed here below the two layers of the pleura. During some violent effort of coughing the portion of diseased tissue between a bronchus and the left pleural cavity gave way. The history places this occurrence at three weeks before death. The pleura was severely infected with tuberculous material and became studded with miliary tubercles. As the direct result of this sudden massive infection of a serous surface generalized miliary tuberculosis arose and provided the final scene.

The absence of disease of the pulmonary hilum glands is interesting in view of Canti's observations³ upon the pulmonary lesions of tuberculosis in children, which suggest that the lung is frequently affected before the glands at its hilum. It seems clear, however, that in this case infection was alimentary and haematogenous, not inspiratory. Unfortunately cultures were not made to prove the class, whether human or bovine, to which the organism present belonged.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

MELÆNA NEONATORUM TREATED BY BLOOD TRANSFUSION.

On February 12th, 1921, I delivered a primipara of an apparently healthy female child weighing 6 lb. During the night the child vomited dark fluid and passed what I supposed to be meconium three times. On the following day the child was very restless and cried considerably. The bowels acted once, the motion still being like meconium. At 1.30 a.m., on February 14th, the baby vomited dark blood, and shortly afterwards passed a large quantity of black, foul-smelling blood from the bowel. Fluids given by the mouth were vomited immediately, and the child appeared to be very ill. At intervals of about two hours alarming quantities of blood were passed from the bowel, and at the same time the child had all the symptoms of a severe hæmorrhage; the skin and lips were almost white,

the heart beats were too rapid and weak to count, the respirations were sighing, and the eyes half-closed. From the symptoms I concluded that the child would die shortly unless blood transfusion could be performed.

As I myself belong to Group IV (universal donors), I drew from a vein in my left arm 20 c.cm. of blood with an exploring syringe into which I had already drawn 5 grains of sodium citrate in sterile solution. I then exposed a vein in the baby's arm by an incision, and exchanging the large exploring needle of the syringe for a fine hypodermic needle injected the blood into the vein of the baby. It was a matter of extreme difficulty to strike the lumen of so small a vein in a collapsed condition, but I was fortunate in injecting the blood without wasting any. The improvement in the child was immediate and striking. The colour returned to the lips, the respirations slowed down, and the pulse at the groin became palpable. During the next twenty-four hours the bowels acted four times, dark blood being still passed, but in diminishing quantities. On the following day the baby took the breast well and the stools gradually became normal. Since then progress has been uninterrupted and the child is now healthy and with a good colour.

Royal Infirmary.

DIPHTHERIA AND FOLLICULAR TONSILLITIS.

DURING the last ten years in a general practice I have been accustomed to divide all cases of sore throat with exudates into three clinical groups: (1) Those which are plainly diphtheria, with an exudate present on other parts as well as on the tonsils. (2) Those which are plainly follicular tonsillitis. (3) Cases which are doubtful but are probably diphtheria; swabs from these cases yielded practically in all instances the Klebs-Loeffler bacillus.

The number of cases in the last group was small in proportion to the other two, about 5 per cent. of the total. I have observed normal convalescence in the follicular group; that there were only four "dissents" in ten years from the fever, hospitals regarding the first group was reassuring. During the later period of the last epidemic, however, I was puzzled by two cases of definite follicular tonsillitis which did not lose the exudate after four or five days, and in each case a swab taken showed, on examination by a pathologist, the Klebs-Loeffler bacillus present. On account of this, swabs were taken from the next ten cases of exudative tonsillitis. In six cases, clinically follicular, the exudate was yellow, soft, pulsatious, in separate patches which did not coalesce and did not spread over the tonsillar boundary; there were no signs of hæmorrhage on removing the exudate. In each case there was marked general malaise, a high temperature (102° or more), and pain on swallowing. In four of these six cases the Klebs-Loeffler bacillus was present, which to me was a startling result.

The other four cases were suspiciously like diphtheria; in them the patches of exudate coalesced, and the spread suggested that the exudate would pass beyond the tonsillar boundary. Of these cases, however, three were negative as regards the Klebs-Loeffler bacillus, and one, the worst, was a case of Vincent's angina.

These results raise in my mind one or two questions. Do epidemics of diphtheria differ as to their clinical manifestations? If not, why were the clinical tests I have been accustomed to apply in former years useless in these cases? Is it not extremely likely that the epidemics are caused by cases so plainly follicular, as far as clinical examination can go, that no swab is ever taken? In the face of the facts given above, is it safe for the general practitioner ever to rely on the clinical signs, however definite, in cases of sore throats with exudates, to give an answer to the question of whether a case is diphtheria or not? I for one, after this experience, will never feel that I can rely on the differential diagnosis by clinical signs.

BRADYCARDIA.

THE following case may be of interest on account of its long duration. We first saw W. W., the patient, fifteen years ago, when he was 70 years of age and was employed as a blacksmith. He complained of attacks of unconsciousness suddenly coming on while at work. These

attacks lasted for about five minutes, and occurred several times during the course of a day. The patient's pulse rate was then 37 a minute, and the attacks were evidently an instance of the Stokes-Adams syndrome. As a result of prolonged rest gradual improvement took place in his general health, and the attacks became much less frequent and finally ceased. During the whole period, however, the pulse rate gradually slowed down to about 25. The previous medical history reveals no illnesses. The patient's general health is now good, but a double senile cataract prevents him from walking much out of doors. In regard to his cardio-vascular system the pulse rate is 25 per minute at the radial artery and at the apex, and the pulse is quite regular. The arteries are extremely calcareous. The apex beat is in the fifth space, $\frac{1}{2}$ -inch outside the nipple line. There is no enlargement of the heart to the right. Harsh systolic murmurs are heard at the apex and the base of the heart. There is no oedema. The other systems show no evident abnormality. We have been unable to have a polygraphic tracing taken, but we consider the case to be one of heart-block.

TREATMENT OF LOCAL LEISHMANIASIS.

I was interested to note the short paragraph by Dr. Norman Gray (March 12th, page 382).

As bacteriologist to one of the large British hospitals in Basra I had an opportunity of studying hundreds of cases of "Baghdad boils." I entirely disagree with the statement that scraping is the best treatment for the infection.

We had tried every possible form of treatment, including scraping, with varying success, but found that the only satisfactory treatment was a full pastille dose of x rays. Previous x -ray treatment had always been disappointing, because, as was pointed out by Major Norman in a War Office Memo. in 1918, the rays had been given in successive small doses. After a full dose rarely was a second dose after four weeks necessary. Healing took place within ten days, and—more important still—one did not have the prominent "bluish" cicatrization which is a feature of all other forms of treatment.

Reports of Societies.

EXAMINATION BEFORE ANAESTHETIZATION.

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine on March 5th, with Dr. H. J. SHIRLEY, President, in the chair, Dr. R. W. APPERLEY read a paper on the importance of the examination of patients by the anaesthetist previous to the administration of anaesthetics. He pointed out that improvements in anaesthesia during the last fifteen years had been not in the increased number of drugs at our disposal but in the variety of more scientific methods of administering them. This placed on the anaesthetist an increased responsibility in his choice of method. There was still room for improvement both in diminishing fatalities and in reducing after-effects, and one step towards this lay in thorough examination of patients some time before operation. The condition of the cardio-vascular, respiratory, and nervous systems could only be ascertained in this way, as well as the efficiency or otherwise of the kidneys. Previous examination gave the anaesthetist time to think out the line of action best suited to the individual. Moreover, cumbersome or elaborate apparatus might be required which would not be present unless the need for it had been appreciated beforehand. The examination was an advantage to the patient, who felt that nothing was being left to chance; to the anaesthetist, who might glean important facts for his guidance; and to the surgeon, who was able to rely on the anaesthetist's guidance as to the patient's ability to stand a prolonged operation. The physician, who seldom saw an operation, was not so well qualified a guide. The risks which a patient ran were not confined to serious operations. For minor ones they were often grave, just because the slightness of the operation led to neglect of necessary precautions regarding the anaesthetic. In private practice

patients in nursing homes were at hand and could be seen on the day before operation. In hospital practice there was routine examination by house officers, and the anaesthetist was supplied with the information acquired. One class of patient which was admitted to the cancer department of the Middlesex Hospital had especially emphasized the importance of a preliminary examination—cachectic debilitated persons, often with secondary growths in the mediastinum or pleura and obstructed air passages. These cases made one extremely cautious in examination before deciding to give an anaesthetic.

Dr. W. J. McCARDIE read a paper on "Explosion of ether vapour during laryngoscopy":

A man of 56 was given open ether to induce anaesthesia for laryngoscopy and removal of a piece of the vocal cord. For some minutes before the laryngoscope was introduced ether with oxygen was given through a nasal catheter in addition to ether from the mask. The mouth being opened, ether and oxygen still passing in through the nose, Mr. Woodman began to introduce Hill's electric laryngoscope. It had not entered more than an inch when there occurred two or three loud reports like small pistol shots, and flames issued from the patient's mouth. These were five or six inches high, and like those seen if a bottle of ether were set on fire. The nasal tube was at once pulled out and the flames quickly died. Anaesthesia was continued with chloroform and oxygen without trouble. There was no obvious burning—merely reddening of the mouth and pharynx—and the patient recovered normally and had no after-cough. At the time of the explosion the room (temperature 65° F.) was lit by two $\frac{1}{2}$ -watt bulbs and one Osram bulb under a shade 2½ feet away almost directly over the patient's head. The bulb of the laryngoscope light did not fuse and the light appeared in order and there was no evidence of short-circuiting.

Commenting on this case, Dr. McCARDIE said that no heat could be felt by the hand when the light was first switched on. The warm room, warm mouth, warm electric light, warm ether and oxygen, would all help towards the explosion. Ether vapour would take fire at a considerable distance from the source of heat. Dr. Squibb had seen ether take fire at a measured distance of 15 feet between the source of escaping vapour and the source of fire. Considering the absolute coincidence of the explosion with the introduction of the lamp, the cause must be found in the electric bulb of the laryngoscope. Dr. McCARDIE related the only other recorded case of ignition of ether vapour in the presence of a closed electric light, and other members of the Section brought forward instances of ether vapour ignition under various circumstances.

FAECES IN ALIMENTARY DISORDERS.

At a meeting of the Pathological Section of the Liverpool Medical Institution, held on March 17th, with Dr. R. W. MacKENNA, Vice-President, in the chair, Dr. ROBERT COOPER read a paper on the faeces in alimentary disorders. He outlined the normal characters of the faeces and emphasized the almost complete absence of food residues in the normal stool. If food residues were found in the stools in any notable amount there was (a) some failure of digestion, or (b) failure of absorption, or (c) hurrying on of the food—that is, diarrhoea. He was convinced that, though specialized chemical operations were sometimes necessary, in most cases a comparatively simple technique was adequate for all clinical purposes. It was essential to control the diet if valid deductions were to be drawn, and drugs should be withheld for some days before examination, especially oily bodies like olive oil and liquid paraffin, and purgatives, which might cause irritation of the gut or interfere with normal digestion. He divided the examination of stools into macroscopic, microscopic, and chemical, demonstrating the methods employed. Macroscopically, the most important abnormalities to be looked for were connective tissue, mucous flakes, and parasites. Slides demonstrated the microscopic appearances of normal and abnormal muscle fibre remnants, fats, starch granules, vegetable debris, etc. The chemical tests for stercobilin, blood, and soluble albumin were outlined, and the value of examining both chemically and cytologically. The value of a saline lavage of the large bowel was emphasized. Two kinds of abnormalities were distinguished—(a) absence of normal constituents, and (b) presence of abnormal constituents. In the first category was stercobilin, derived from bile pigment by the reducing action of the intestinal bacteria, absence of which indicated that bile was not reaching the intestine. In the second

category were certain food residues, blood, soluble albumin and mucus. The appearance of connective tissue in any notable amount in the stools proved that there was failure of gastric digestion. The significance of imperfectly digested voluntary muscle fibre was discussed and two types of associated digestive trouble were mentioned—(1) those associated with definite pancreatic insufficiency, and (2) those in which there was no satisfactory evidence of pancreatic trouble. In both cases there might be excessive protein putrefaction in the large intestine, with indoxyluria, colitis, and sometimes general toxæmic symptoms. The abnormal presence of starch grains often indicated nothing more than a diarrhoea, sometimes the condition of so-called "carbohydrate dyspepsia," which was due either to excess of carbohydrate food or to some infection or catarrh of the small intestine. He did not regard it as indicative of pancreatic disease. As regards fat, Dr. Coope thought there were two fundamental questions to ask: (1) Was there excess of any type of fat in the stool? (2) If so, was it an excess of split or unsplit fat? In his experience microscopic examination was usually quite adequate for clinical purposes. As the important point in the latter question was to learn whether the neutral fat of the food had been split into glycerin and fatty acid to the usual extent, no clinical purpose was served by distinguishing between the two types of split fat—namely, free fatty acids and soaps. Absolute excess of unsplit fat indicated pancreatic insufficiency, or a rapid passage of food through the intestine (for example, gastro-colic fistula). Absolute excess of split fat might indicate (a) marked diarrhoea, or (b) pancreatic insufficiency where means other than the pancreatic juice had split the fat, or (c) lack of absorption due to absence of bile or to disease of the gut wall (for example, sprue, amyloid disease). The significance of blood and soluble albumin were then discussed. Mucus was normally unrecognizable, but might occur abnormally as flakes intimately mixed with the faeces, incorporated in the small intestine or in the initial portion of the large bowel, where the faeces were still fluid. In such cases the cause was probably irritation, bacterial or chemical, of the gut wall, or possibly diarrhoea. Again, it might occur as mucus surrounding the formed faeces, produced in the terminal portion of the large bowel. Here it was usually due to constipation. In putrid fluid faeces, as in typhoid, the abnormal mucus might be digested and not appear in the stools at all. Dr. Coope then cited various cases illustrating the value or otherwise of various findings in the stools.

PUBLIC HEALTH LABORATORIES AND PREVENTIVE MEDICINE.

At a meeting of the Society of Medical Officers of Health, held on March 18th, with the President, Lieut.-Colonel F. E. FREMANTLE, M.P., in the chair, Dr. A. T. NANKIVELL opened a discussion upon "The relation of the laboratory to preventive medicine." After referring to existing county and county borough laboratories, he said it was doubtful if it was desirable to multiply the number of small laboratories; though where the medical officer of health was sufficiently qualified, a small laboratory properly staffed might be most useful, especially in speedily dealing with diphtheria specimens. He advocated wholesale swabbing of school children in face of an outbreak of diphtheria, and deprecated the practice adopted in some of the hospitals of the Metropolitan Asylums Board of discharging diphtheria patients without previously taking swabs of them. He urged every medical officer of health who had a laboratory to undertake some research work.

Dr. E. W. GOODALL said that he had given up the routine practice of requiring two negative swabs before discharging a patient from hospital, and he found that his results were quite as good, if not better, than in those hospitals where swabbing was resorted to. Surgeon Rear Admiral BASSETT-SMITH, Dr. MONCKTON COPEMAN, and other speakers insisted that the virulence test must be applied when deciding whether a positive result was really dangerous. The President said that the war had opened our eyes to the fact that the laboratory had a wider view than that of the prevention of diphtheria. In

Mesopotamia plague could not have been kept down without the assistance of the laboratory, where rats could be quickly examined and the affected bazaar located. He disapproved of the setting up of small laboratories.

Reviews.

CEREBRAL DEVELOPMENT AND FUNCTION.

In 1894 Dr. PAUL FLECHSIG delivered his memorable address at the University of Leipzig, afterwards (1896) published in the book entitled *Gehirn und Seele*. His pioneer researches were of epoch-making importance, for he showed that there was a time correspondence in the myelination of neuronic systems, during the development of the central nervous system and their manifestation of function. Although the hopes that were entertained by Flechsig and his followers regarding the possibility of an anatomical explanation of cerebral function have not been fulfilled, yet certain fundamental principles have been established.

The method of study which he employed was a systematic examination of sections of the brains of a number of foetuses, of newborn infants, and of infants of various ages after birth stained by the Weigert-Pal method. He was able to determine the successive stages in the myelination of neuronic systems and the times in which these appeared. The inference that myelination is indicative of preparedness for function is the fundamental principle, and in the main Flechsig's investigations are in accordance with the psycho-physiological evolution of the child.

The structures at the base of the brain, for the most part, and the cerebellum were found to be myelinated before birth; whereas in the newborn infant the cerebrum only exhibited isolated regions of myelination around the primary fissures—namely, the central, calcarine, and the Sylvian; these are the regions of the primary projection centres of movement and of the special senses. The remainder of the cortex is not myelinated, and constitutes the association centres, as yet unprepared for function. Upon anatomical grounds, therefore, it may be postulated that a child at birth may have a simple sensation. Since after birth every visual or auditory sensation tends to activation, especially to exploratory tactile-motor reactions, simple sensations give place *gradatim* to more and more complex perceptions and memories of the associated experiences; correspondingly there is more extensive myelination indicative of preparedness for these increasingly complex functions of perception and memory.

Flechsig's new book¹ is a continuation and extension of these studies. He divided the cortex according to myelogenesis but without regard to the anatomical point of view into primordial, intermediary, and terminal areas. The plates, twenty-five in number, are extremely well executed, and exhibit in a striking manner the successive stages of prenatal myelination, commencing with the brains of foetuses of 32 to 43 cm. long; they show also post-natal myelination of premature and normal newborn infants that had lived days, weeks, and months—the oldest being 9 months—and lastly the brain of an adult aged 40 years. Whether all the intermediary and terminal areas of myelination described by Flechsig can be supported by these investigations or not, they show clearly that there exist three areas of successive myelination—namely, (1) primary sensory-motor, adjacent to primary fissures; (2) psycho-sensory-motor cortical areas, adjacent to the primary sensory-motor areas; and (3) terminal associational, in the frontal, temporal and parietal lobes. This myelogenic evolution, indicative of preparedness for function, in a broad way conforms to the phylogenesis of the cortex. In the primordial region we find interposed in the normal cell lamination neurones which serve as the arrival and departure platforms of sensory-motor impulses. In the adjacent psycho-sensory-motor areas (intermediary areas of myelination) there is a characteristic cell lamination, and it may be postulated that these areas are concerned with elaboration of the sensory-motor functions of the primordial

¹ *Anatomie des Menschlichen Gehirns und Rückenmarks auf Myelogenetischer Grundlage*. By Paul Flechsig. Leipzig: Georg Thieme. 1920. (Demy 4to, pp. 121; 25 plates, 8 figures. fl 5s. 8d.)

regions, whereas the terminal areas of the frontal, parietal, and temporal lobes are especially concerned with the integration of the primordial and intermediate areas. The first evidence of association is in the corpus callosum, which associates the sensory-motor functions of the two hemispheres. Myelination can be seen commencing in this structure in the newborn full-term infant. When there is evidence of complete myelination the whole cortex is prepared for function, and there is a psychic unity whereby the whole seat of consciousness is involved in even the simplest action.

The more important conclusions stated by Flechsig in this volume may be stated as follows: With full-term birth cortex fibre myelination is divided into two approximately equal phases of four months each. In the pre-natal period sixteen primordial areas of myelination can be differentiated, ten of them being sensorial areas and six of them autonomous fields of unknown significance. After birth the fibres medullated are at first related to those already functioning. But later on two new groups mature, the one consisting of projection systems related to the primordial areas and in anatomical juxtaposition to them; the second group of terminal areas has representatives centrally situated in the frontal, parietal, and temporal lobes respectively, and their function is to co-ordinate all the projection systems around.

In all, Professor Flechsig differentiated forty-five areas of myelination in the cerebral cortex, and his studies also mark off certain very definite tracts in the white matter. He proceeds to correlate these findings with those from pathological secondary degenerations obtained by other observers, and he considers that the following deductions can be drawn:

In the first place, those areas whose destruction causes sensory or motor loss coincide with his primary sensorial areas. Secondly, one primary sensorial area is not directly connected with others, nor is it in promiscuous relationship with the whole of the remaining cerebral cortex. The only exception which appears likely concerns smell and taste, whose areas are in intimate interrelationship. A developmental study of the fasciculus longitudinalis inferior shows that it consists of smaller units, and Professor Flechsig protests against findings in the lower mammals being hastily assumed to hold good for man. Between two primary sensorial areas intervene at least two bordering zones, and, in addition, perhaps a terminal area.

He thinks it probable that the study of aphasia will demonstrate that memory pictures of sensations are preserved in the intermediate areas bordering on the sensorial, but whether the terminal areas are to be regarded simply as organs for associated memory traces must be left for future investigation to determine. It may also show that the cortex can be regarded functionally as divisible into territories, related each to a sensorial area, and concerned in the elaboration of one kind of sensory data.

The study of myelination throws an interesting light on the composition of the corpus callosum, which develops *pari passu* with the cerebral cortex. This study has important bearings on macroscopical brain anatomy also. For example, the Rolandic fissure separates the frontal and parietal lobes, and yet it is placed in the centre of a small area which has a distinctive development of its own. Again, other sulci are in juxtaposition to several areas of widely different development. Sulci in relation to the primary sensory areas, such as the Rolandic or calcarine fissures, are constant; those of later development vary widely in situation. The first temporal convolution is always related to auditory sensations, but, on the other hand, the third frontal convolution includes three areas differing in myelogenesis.

Professor Flechsig finds that his frontal and parietal terminal areas correspond exactly to the frontal and parietal eminences, and he holds that within narrow limits, and more especially in the child, the extent of development of these areas affects the shape of the skull.

This book can be commended, not only for the account of the valuable researches it contains, but also for the excellent way in which it is illustrated by coloured plates with descriptive text.

NERVE INJURIES.

THE volume, *Injuries of the Peripheral Nerves*,² is in many respects a challenging book, in many respects an admirable one. We can imagine that some who have saturated themselves in the subject of nerve injuries will disagree with a number of things to which Mr. SOUTTAR commits himself without a tremor or a hint that any other manoeuvre might be tried in its place. But since very few are in agreement on certain aspects of this vexed subject, this is not an essentially important point. Unanimity of opinion is not yet to be found, particularly as regards the results of various kinds of operations. This book must be taken as giving us the views of Mr. SOUTTAR and Mr. TWISING on nerve injuries. No one reading it will be in any doubt as to what the authors' views are. They are clearly and dogmatically expressed, so that those who have only an elementary knowledge of nerve injuries can pick the book up and quickly render themselves much wiser men.

The arrangement of the chapters is excellent, and the authors have been well advised in keeping them on the short side. No lack of continuity has resulted from this, and it makes the book vastly easier to read. The changes in the nerve itself following injury are lucidly described, and a chapter is given to that vital point—changes in the surrounding and distal tissues and the influence of such changes on the final result obtained. Then follows a short account of the methods of examination of these cases in general and of the various nerves in particular, illuminated from time to time by short histories of cases. These have been well chosen, and include civilian injuries as well as war wounds, thus rounding the tale to its great benefit.

Descriptions of the technique of operations of various kinds occupies a great part of the book. Exception must be taken to the drawing tight of the tension suture in end-to-end junction of the divided nerve. Indeed, individual operators will find in the pages hereabouts a great deal with which they may disagree. Particularly is this the case with the "bulb-flap" operation figured on pp. 76 and 77, a proceeding physiologically unsound, although the author claims a success for it in Case 14. A similar objection will be raised with regard to the anastomosis or shunting of the distal end of a divided nerve into the side of a nerve previously sound. The authors state that the operation can be carried out without any permanent injury to the contributory nerve. They state that one third of any ordinary nerve may be divided without any permanent loss of function. This is tantamount to saying that any nerve injury which involves not more than one-third of its fibres will lead to no disability of moment. We should have imagined that their experience with nerve injuries would have taught them that this is too sweeping a statement altogether. In spite of these objections Mr. Souttar and Mr. Twining are to be congratulated on a good piece of work. They have made the subject easy, indeed too easy. For after reading this book the uninitiated will believe that nerve injuries are rather simple things with which to deal.

We will not close this notice without a few words of congratulation to Messrs. John Wright, the publishers. They have produced a book which, in these degenerate days of printing and binding, it is a pleasure to handle.

PSYCHOLOGY AND PSYCHOTHERAPY.

DR. WILLIAM BROWN has published a number of articles on the psychological principles which underlie the modern theory and practice of psychotherapy, and in his book entitled *Psychology and Psychotherapy* he evidently intends to develop his views in more systematic form. This aim has not been quite successfully accomplished, and it would probably have been more satisfactory if Dr. Brown had decided to publish his book merely as a collection of essays on psychological topics. As it is, there are abrupt changes of theme, a number of repetitions, and a relative absence of a progressive development of any particular line of thought; all this rather tends to bewilder the reader.

² *Injuries of the Peripheral Nerves*. By H. Souttar, C.B.E., F.R.C.S., M.Ch.Oxon., and E. W. Twining, M.R.C.S., L.R.C.P., Bristol. John Wright and Sons, Ltd., London: Simpkin, Marshall, Hamilton, F. & Co., Ltd., 1920. (Roy. 8vo. pp. 162; 20 figures. 13s. 6d. net.)

³ *Psychology and Psychotherapy*. By William Brown, M.A., M.D., Oxon., D.Sc.Lond. With a foreword by William Alden Trier, C.B., M.D., London: Edward Arnold, 1921. (Cr. 8vo. pp. xi+172. 8s. 6d. net.)

Much attention is given to Freud's views, and a number of critical comments are made in respect to them. Dr. Brown does not accept the theory that the psychoneuroses are invariably the expression of maladaptation in the sexual sphere, but he has found the psycho-analytic method a valuable therapeutic measure. He does not, however, employ this method in its pure form, but relies largely on what he terms autognosis for the treatment of his cases. While "free association" forms part of his treatment, he utilizes explanatory, persuasive and suggestive methods as well. We believe that Dr. Brown is perfectly right in stating that suggestion plays a large part in the psycho-analytic method. It certainly does if we can go by the published accounts. It is frequently stated in authoritative psycho-analytic journals that the analyst points out to the patient the sexual symbolic meaning of the manifest content of his dream. This is, of course, direct suggestion, but, as the author observes, it is impossible to exclude unconscious suggestion however carefully the psycho-analytic technique is carried out. He expresses the view that there are four fundamental and relatively independent psychic factors at work in the cure of mental illness, namely, psycho-synthesis, psycho-catharsis, autognosis, and the personal influence of the physician.

In the sphere of purely academic psychology Dr. Brown contributes an interesting chapter on the theories as to the relation of mind and brain. He gives an account of Bergson's interaction theory, and himself favours the views expressed in *Matter and Memory* rather than the parallelistic hypotheses. It would have been of service if the author had developed these questions rather more fully, but he has suggested points of view which are of definite value. We note with a certain amount of surprise that Dr. Brown refers to telepathy almost as if it were a subject which had reached a stage of proof and was no longer debatable.

Though certain criticisms of this book have suggested themselves, it contains, as might be expected in view of the wide knowledge of the author, many features of interest to the psychopathologist.

DISEASES OF INFANTS AND CHILDREN.

PROFESSOR CROZER GRIFFITH, of Philadelphia, has written a comprehensive book on *The Diseases of Infants and Children*.⁴ It is founded on a long experience of hospital and private practice, and of teaching. The arrangement of the volume follows the usual plan, beginning with the anatomy and physiology of child life, infant feeding and relative food data, passing to infectious and general diseases, and then dealing with diseases of the various systems. The number of illustrations, both photographs and clinical charts, is large, and the short reports of cases appended increase the clinical character and practical value of the book, and can, indeed, be studied independently of the text. The coloured plates are also to be commended, especially those of the infant's normal and abnormal stools. The numerous references to medical literature include not only current, but also historical literature. Indeed, they are so numerous as sometimes to overload the text and obscure the author's own individual experience.

The book is as nearly encyclopaedic as it is possible for the book of one man to be, yet the treatment of some important aspects of disease in children is curiously slight. In dealing with rickets and scurvy, recent important work upon vitamins is merely mentioned. Also, America has in the last five years produced many careful and illuminating investigations upon clinical types of anaphylaxis and their diagnosis by the specific protein tests, yet this subject is only glanced at. The large subject of mental defect and imbecility is compressed into ten pages. These, however, are small defects in comparison with the great merits of the book. Above all other things, it bears the stamp of long and sound clinical experience—nearly forty years of practice and teaching; and the author's very numerous contributions to medical literature have already made his name familiar to practitioners on this side of the Atlantic. The book will be valuable not only to the specialist in the subject, but also to the practitioner in his daily dealings with sick children.

⁴ *The Diseases of Infants and Children*. By J. P. Crozer Griffith, M.D., Ph.D. Philadelphia and London: W. B. Saunders Co. (Double Roy. 16mo; 2 vols., pp. 835 and 657; with 436 illustrations, including 23 coloured plates. 72s. net.)

DISEASES OF THE NEWBORN.

WHEN, in 1914, Dr. RITTER VON REUSS's work on the diseases of the newborn appeared in Austria, it was reviewed at some length in the pages of this JOURNAL (1914, vol. i, p. 918), and the opinion was expressed that it constituted a safe and reliable guide in dealing with the diseases of early life. A great deal has been written about neonatal diseases since 1914, and the whole subject has been greatly advanced; in particular, a resolute effort has been made to understand better and to treat more effectively the maladies of the first month of life, bearing in mind that at no other time is mortality so high. The English translation, published under the title *The Diseases of the Newborn*⁵ is therefore welcome. There are one or two slightly mysterious features about the volume. The title-page, (which bears the date 1920) shows no name of a translator, although, let it be said at once, the rendering is admirable. On the paper cover, however, Dr. John D. Rolleston is described as the reviser of the translation. Further, there is no preface or prefatorial paragraph explaining the purpose or the occasion of the translation. Curiosity regarding these matters remains unsatisfied. The reader will, none the less, be glad to have Dr. von Reuss's work in its English dress. There is a very long bibliography of some fifty pages, but it is weak in its references to British contributions to neonatal pathology and medicine; for instance, Ashby and Wright only appear in a secondary fashion as quoted by another author, and not a few of the original titles of English articles are lacking, being represented by what seem to be headings from foreign literature lists. The publishers, however, have turned out the work sumptuously, and deserve a word of praise.

NOTES ON BOOKS.

MR. PAUL BOUSFIELD feels that there is no book on psycho-analysis which exactly meets the needs of the practitioner unversed in the technicalities of psychology and psychotherapy, and his book on *The Elements of Practical Psycho-Analysis*⁶ aims at remedying this deficiency. In view of the enormous output of literature dealing with this subject it would seem that there must already be plenty of books from which the practitioner might make a selection, and it is thus somewhat difficult to support the author's contention. In any case the influence which Mr. Bousfield anticipates the new psychology will have on future social customs is so unattractive that many readers will be tempted to wish a speedy end to the whole movement as he presents it.

In his book on *Psychoanalysis: its History, Theory, and Practice*,⁷ Mr. ANDRÉ TRIDON endeavours to present an unpartisan treatment of his subject. He deplores the antagonism between the leaders of the various schools of thought, and attributes this mainly to personal animus among them. The author covers a wide range of problems which he seeks to interpret in accordance with the theories of Jung, Freud, and Adler. The same author is responsible for another book on similar lines entitled *Psychoanalysis and Behaviour*.⁸ Here he shows himself strongly influenced by the work of Dr. Edward J. Kempf, and he gives a useful outline of his theories of behaviour. There is little doubt that Dr. Kempf's physiological interpretations of human reactions are of considerable significance, and they may do much to replace the metaphysical formulations of Freud and Jung, though his actual views are inspired by Freud to a large extent.

The issue of *Medical Science, Abstracts and Reviews* for April is the first number of a new volume—the fourth. It contains, among other reviews, one on alimentary diseases, with a copious bibliography, and another on non-tuberculous juvenile coxalgia. Two indexes to Volume III are supplied, the one of subjects and the other of authors.

⁵ *The Diseases of the Newborn*. By August Ritter von Reuss, Director of the Department for the Newborn at the First University Women's Clinic in Vienna. Translation revised by John D. Rolleston, M.D., B.Ch., M.A., Oxon., assistant medical officer, Grove Hospital, Tooting. London: John Bale, Sons, and Danielsson, Limited. 1921. (Roy. 8vo, pp. 638; 50 figures. 52s. net.)

⁶ *The Elements of Practical Psycho-Analysis*. By Paul Bousfield, M.R.C.S., L.R.C.P. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1921. (Demy 8vo, pp. viii+216. 10s. 6d. net.)

⁷ *Psychoanalysis: its History, Theory, and Practice*. By André Tridon. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1921. (Cr. 8vo, pp. 272. 10s. 6d. net.)

⁸ *Psychoanalysis and Behaviour*. By André Tridon. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1921. (Cr. 8vo, pp. 354. 10s. 6d. net.)

EIGHT of the principal publishing houses in Paris which issue medical and scientific books have combined in the production of a *Bibliographie des Livres Français de Médecine et de Sciences*. It is a joint catalogue of books published by the eight firms in the years 1908-20. The books are classified according to subject and particulars as to size and price are given. The volume is provided with an index of authors' names and with a list of periodical publications. It is a new departure very much to be commended and one worthy of imitation. Copies can, we understand, be obtained on application to the Section de Médecine du Syndicat des Éditeurs, Hôtel du Cercle de la Librairie, Boulevard Saint-Germain, 117, Paris (VI^e).

MEDICINE IN PUBLIC LIFE.

MEDICAL DINNER AT EXETER.

THE Minister of Health, Dr. Addison, was the chief guest at a dinner given by the Mayor of Exeter (Mr. Arthur C. Roper, F.R.C.S. Edin.) to the members of the medical profession at the Guildhall, Exeter, on March 30th.

Proposing the health of Dr. Addison, Dr. ROPER said no function during his term of office, so far, had given him greater pleasure than that of entertaining a large number of his professional friends, old and young. Some, but not many, were his seniors; a good many were his contemporaries; others were his juniors, and some of them he knew very well and intimately. Referring to the presence of the Minister of Health, the Mayor said that Dr. Addison occupied a unique position in the medical profession. He was looked upon from widely divergent points of view, but, whatever the view, they must all recognize him as one of themselves—(Hear, hear)—as one who, equally with themselves, was doing his best to serve and to benefit the health of the nation. In asking the company to drink Dr. Addison's health, Dr. Roper wished him every success in piloting the ship that bore a precious cargo safe to the haven where he would receive the gratitude of a benefited and healthy nation. (Applause.)

SPEECH BY THE MINISTER OF HEALTH.

Rising to respond, Dr. ADDISON received an ovation. He said the man who deserted a professional career and entered upon the uncertain path of a political life was looked upon somewhat as a suspect by the average professional man. He was glad that, at all events, the citizens of Exeter had recognized that medical men in their city council could and ought to render service. And what was true of the city of Exeter he thought ought to be true in the councils of the State. It always seemed to him to be a singular drawback to their profession that, immersed as most of them were in attendance upon the individual, they were apt to overlook, or perhaps they had not time to think about, the community of which that individual formed but a single part. They did not require to think far before coming to recognize that there were some things which as professional men they knew should be done, and could be done, but which could not be accomplished under any circumstances by individual effort. They could only be brought about in some measure by the collective action of instruments of government in some form or another. He believed that a good many medical men regarded the medical politician as a suspect because they did not quite see what he was getting at. The reason for that, he thought, was because their profession was so interesting and their work so absorbing that they had neither the time nor the disposition to study health questions from the State point of view. Whether or not that was the explanation, he recognized the fact and endured it with all the fortitude he could. While there had grown up in this country a collection of responsibilities, powers, and duties, scattered about through various departments of the State, concerned more or less with promoting, preserving, or protecting the life and health of the individual citizen, they had never been brought together, organized collectively, and directed as one so far as was possible. The Ministry had not yet been at work very long; it had had a good many teething troubles—(laughter)—while they were not without their critics—(renewed laughter)—especially in certain sections of the Press, who were much interested in the promotion of a "stunt," as they called it, or in ventilating a personal grudge sometimes against a Minister of Health—he being, for the moment, a useful vehicle—but who were not so

anxious perhaps at all times to state or consider the facts of the case on their merits, and so it came about that there were many things which had never been stated or even understood.

Housing as a Preventive Health Service.

In the first place he thought that the organization of the health services of the State and their development ought to be with the Government the motive for increasing the value and efficiency of the services for the prevention of sickness and disease. No subject undertaken at the Ministry of Health had brought them more ridicule, should he say, than that of housing, but he put housing first as a preventive health service. A start had been made, and they at least knew where they were going. For the first time a duty had been cast—and he did not apologize for its being a duty—upon local authorities to make a return as to what were the needs of the community in terms of houses. According to the 1911 standard two million people were said to be living under insanitary conditions. Well, he wanted to alter that standard. It was useless to talk of stamping out tubercle when so many people were compelled to live in houses condemned as unfit for human habitation. It might well be that it would take twenty years to get the rehousing of this country on a well established basis; but that was a matter of no consequence. What mattered was that they had obtained a minimum standard based upon the health requirements of the nation affecting the lives of the people two-thirds of the hours they lived. The measure was more essential, he believed, to improving the health and well-being of the child and other population than any other one measure that could have been taken up. (Applause.) It was true they had been beset with all manner of difficulties, but they had ploughed their way through some of them. No enterprise had ever succeeded without difficulties, and they would be overcome in time. Soon they would be coming to the second stage—the allocation to every city and town within the limits of finance available a sum to help in dealing with the insanitary dwellings in their midst, and he believed the views of the medical profession thereupon would be unanimous. (Applause.)

Medical Guidance in Public Affairs.

Proceeding, Dr. Addison said there could be no doubt that the medical profession would, more and more, be forced into public affairs. Public opinion and the spread of education would do it. It was one of the first requirements of their profession that there should be bodies of men in the different districts, and some bodies central, who were accustomed to meet together to consider and discuss public questions in which professional knowledge or interests were concerned, so as to obtain from time to time as required, and to be able to give, responsible and considered professional advice. Public bodies and also the State, he thought, had often gone wrong, or missed an opportunity because it had not had the guidance and advice from those, and those only, who knew—advice which it might have been possible to obtain. So it had come about that they had had difficulties owing to the lack of such advice, and he repeated what he had already said in London a short time ago—the request to his professional brethren to get busy on this matter.

Going on to refer to the question of hospitals, the speaker said the great masses of the people were needing more expeditious hospital treatment and that the accommodation available for them in the voluntary institutions at the present was insufficient. Side by side with this was the mass of empty accommodation, and it was impossible to think that they could go on for ever like that. There was the demand on the one side and the supply on the other; but the two never met, and because the Ministry were venturing to think a little in advance they got into trouble; still they were going on with it all the same. (Applause.) With regard to the cancer problem, Dr. Addison said he should like to see a more comprehensive attempt made to tackle it. Looking at the results from such knowledge as could be gleaned, it did not seem to him that they were much further ahead as yet. The tale of death was still as great, if not greater, and he thought there was a big opportunity for a wise expenditure of money in the interests of

economy. (Hear, hear.) Statistics showed that in 1918 58,000 died of tuberculosis in this country, the previous lowest year being 1913, when there were 49,000 deaths. In 1919 the number fell to 46,000, and last year it dropped to 42,000. As to the cost of the whole tuberculosis service, taking the country as a whole, it worked out at rather less than a penny rate in regard to expenditure of local authorities, and a farthing out of every £ in regard to the Exchequer. With regard to infant mortality, the death-rate in London fell to 85 in 1919, and last year was down to 75. He understood it was still going down, but it could go down to 50 if only they did the job properly.

In conclusion, Dr. Addison said that preventive medicine was the cheapest investment for the State. Well-considered and well-directed health efforts were cheap and paid, and they were only just beginning to see it in this country. But as they came to see it, the medical profession would be dragged right into it; of that there was no question, and therefore he had no manner of doubt that, as on every other occasion which had called for their response, they would rise to it quite easily in their singularly characteristic British fashion. But he was quite sure that the time was at hand, and great would be their opportunity. (Applause.)

INDUSTRIAL FATIGUE AND VENTILATION.

THE latest report of the Industrial Fatigue Research Board consists of a volume of preliminary notes on atmospheric conditions in boot and shoe factories.* The first report of this series, which was mainly introductory, gave a short history of the industry and a condensed description of the processes carried on, and also certain information relating to individual differences in output.

The present report, which deals with the practical use of the kata-thermometer as an indicator of atmospheric conditions from a physiological aspect, is based upon observations made in a number of boot and shoe factories under varying conditions, and also, for purposes of comparison, in an aircraft doping room. The kata-thermometer, it will be remembered, was devised by Dr. Leonard Hill in the course of his researches into the subject of ventilation. It is designed to measure its own rate of cooling at a temperature approximately that of the human body, and has an alcohol reservoir in the form of a cylindrical bulb, a stem graduated in tenths of a degree from 95° F. to 100° F., and at the top a small bulb, which acts as a safety overflow when the thermometer is heated, and readings are taken with the "kata" used both as a dry bulb and as a wet bulb thermometer. Hitherto no systematic attempt has been made to investigate on a large scale the particular aspect of ventilation which determines the physiological state of the person exposed to it—that is, the cooling power of the air—in order to correlate it with fatigue and production. A means of measuring this effect is now, however, afforded by the kata-thermometer, and it was accordingly decided to start a series of observations in boot and shoe factories with the object of studying the importance of this factor of the workers' environment.

The inquiry has not yet progressed far enough to justify any definite conclusions as to the relation of atmospheric conditions to fatigue and efficiency, but, having regard to the novelty of the method of observation involved, there is a certain advantage to be gained by the publication of this preliminary report indicating the conditions actually existing in different departments. The kata-thermometer deals only with the physiological effect of ventilation, as measured by the cooling power of the air. It takes no count of other aspects of ventilation such as the avoidance of infection and the rate of change of the air in the room—that is to say, the replacement of stale air by fresh. This instrument, moreover, is much more susceptible to local conditions than is the thermometer, so that any given reading can only be taken as applying to the point of observation. It is designed to measure rates of cooling that are dependent on temperatures, humidities, and velocities of air currents, and rates of cooling give information with regard to standards of comfort and efficiency.

As the result of the investigations, which were carried out first under the direction of Professor T. Loveday, M.A.,

and later of Professor E. L. Collis, M.D., the report points out that an atmosphere which will help to sustain physical energy should be cool rather than hot, dry rather than damp, and there should be brisk air movement. Neglect of these conditions may cause physical disability and inefficiency.

There is some evidence to show that atmospheric conditions deteriorate from morning to evening in the workshop, and also that this makes additional demands on the workers' energy. Examination of summer and winter records taken at several factories suggests that systems of ventilation which are adequate in winter cannot always ensure desirable physical conditions under adverse outdoor conditions in summer. Machinery in motion has an appreciable effect on atmospheric movement, and careful consideration should be given to the ventilation in small rooms used for special processes which are shut off from main air currents. Consideration of ventilation in single and multi-storied buildings indicates that the latter structures have slightly higher rates of cooling, a narrower range from winter to summer atmospheres, and a greater air velocity. Experiments carried on in an aircraft doping room showed the high rates of cooling, obtained by frequent air change at high velocity, and the application of the doping-room system of ventilation to boot and shoe factories was considered. A study of the atmospheric conditions in the principal departments suggests that rates of cooling and atmospheres were not adapted to the nature of occupations. For instance, there was some indication that "clicking" rooms were too cold in winter and too hot in summer; that the air velocities in each department were greater in summer than in winter; and that the summer rates of cooling in press rooms were below the standards recommended. In other departments, such as lasting and finishing rooms, where heavy manual work was in progress, rates of cooling and atmospheres for both summer and winter were found to be unsatisfactory.

An interesting section of the report shows the effect of clothing on skin temperatures, and the principle is illustrated that comfort during working hours could be enhanced by a more careful choice of clothing. Conversations with operatives showed that the heavy worker too often has the idea that profuse perspiration is a necessary consequence of his occupation, and he guards against chill by wearing heavy woollen garments which absorb moisture; but light clothing would be preferable because of its effect in allowing the free circulation of air between the garments and the skin.

This report is a further example of the useful work that is being carried on by the Industrial Fatigue Research Board, and gives one more reason—if that were needed—why this work ought to be continued for the benefit of the nation as a whole.

PRESENTATION TO DR. J. A. MACDONALD.

THE following further subscriptions have been received from March 1st to April 4th, 1921, in response to the appeal published in the JOURNAL of July 24th, 1920 (p. 129), towards a presentation to Dr. J. A. Macdonald on the occasion of his retirement from the office of Chairman of Council of the British Medical Association which he had held for ten years. Subscriptions of any amount not exceeding five guineas should be made payable to "The Macdonald Presentation," and sent to the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2.

THE SCIENCE OF ETIOLOGY.

IN the mid-Victorian period the students of infectious disease had practically only two weapons, the clinical and the statistical. The former gave us such fundamental observations as the discrimination between typhus and typhoid fever, the latter a long series of fruitful generalizations, particularly as to water-borne disease, associated in this country especially with the names of Simon, Radcliffe, Buchanan, and Power. This was succeeded by a period during which thought was dominated by the astonishing achievements of the bacteriologists with regard to etiology, which the more sanguine spirits hoped would prove to be at once directly applicable for prevention. A great deal was accomplished, but not all that was hoped or even promised, and an inevitable reaction ensued, which was presently reinforced by the appearance of a new school of statistical epidemiologists provided with mathematical methods unknown to its Victorian predecessors. If to the plain man bacteriologists seem to have gone too far in apparently ignoring all but the bacterium, the new statistical etiologists seem to have proceeded to the verge of the absurd.

It was such considerations that induced us to publish, in our issue of March 19th (p. 432), an article entitled "The New Epidemiology." In it we endeavoured to point out that to ensure its future progress epidemiology must make use of two different implements, the bacteriological and the statistical, the underlying assumption being, of course, that both must rely for their fundamental data on clinical medicine. That both methods, bacteriological and statistical, must be used in the study of etiology might seem to be a truism, but we were quite prepared to incur a charge from either side of obscurantism, although pains were taken to avoid affording any justification for it. The accusation has come from the bacteriological side, and we take pleasure in publishing—for the subject is of immense importance—the following criticisms from the pen of a distinguished bacteriologist, written, as we understand, in consultation with a no less distinguished clinician.

"If Medicine," they write, "is not yet an exact science, it is doubtless because our experiences of disease, and our efforts to control it, yield exceedingly difficult material upon which to base sound conclusions. But the complexity of the processes involved, and the gaps in our knowledge, must not blind us to the greatness of the achievements of research. And since most of the advances in Medicine of recent years have been made possible by progress in our knowledge of causation, the growing science of etiology may be regarded as a sure measure of progress. An exact knowledge of causes is one of the most difficult and elusive of all quests in Medicine. In the case of the infective diseases, where some of the chief progress has been made, the problem is complicated by the circumstance that two of the factors involved are living organisms of independent vitality, of complex physiology, and each imbued with a tendency to vary. The causes of these variations

both of microbe and host have still to be adequately determined."

"It would appear," they continue, "that there are at least two procedures for advancing the science of etiology. The first, which is the method of the vast majority of research workers to-day, may be described as follows: By persistent endeavour; by a patient and accurate collection of facts; by well-controlled and repeated observation; by appropriate and 'light-giving' experiment; by withholding conclusions until the ascertained data are adequate; and, finally, by considering all the evidence with due regard to each portion of it, to arrive slowly perhaps, but nevertheless surely, at certain knowledge. The method of the newer science of epidemiology is distinct from this. Instead of accumulating facts in laborious fashion, it aims at a solution of the problem by postulating causes and apparently by eliminating the principle of specificity. It may readily happen that a plausible explanation of any set of phenomena can be found which may satisfy the imagination of the time being. The ultimate value, however, of such a hypothesis depends not only upon its ability to account for a certain set of observed data, but upon its fate when tested by the stern reality of experience in the widest sense. Not the least valuable of the services rendered by bacteriology was the prompt dispersal which it effected of the dim mists of 'miasmology.' It is possible that the practical physician who finds that small-pox is derived from small-pox, measles from measles, and tuberculosis from tubercle, will be more inclined to believe in the strict specificity of such diseases, and in accumulated experience, than in a conception, however elastic and 'gap-filling'—such as that put forward by some of the exponents of the newest statistical epidemiology.

We venture only one comment, which is that it would be a mistake to limit the term "research" to experiments in bacteriological and chemical laboratories; we feel sure that our correspondents did not intend so to limit it, but on a hasty perusal it might seem as though they did.

RECURRENCE OF BILIARY CALCULI.

IT is well established that calculi may re-form in the gall bladder after the operation of cholecystostomy and removal of what foreign contents there may have been within. This is, in fact, one of the chief arguments put forward in favour of cholecystectomy as against mere drainage. It is, however, known that trouble may sometimes recur after removal of the gall bladder entire, that such removal is not an absolute insurance against further biliary trouble. Some persistent discomfort in the right hypochondrium may be due to infective cholangitis or lymphangitis within the liver itself—a gall-stone cirrhosis. This complication is usually of a low grade and of far from obvious symptomatology, and yet commoner, perhaps, than we realize.¹ But the chief and disturbing trouble which is liable to cause distress to the patient and discomfort to the surgeon is the recurrence of biliary colic after cholecystectomy has been well and truly performed.

Undoubtedly the most fertile source of after-trouble is the incomplete removal of stones at the primary operation. Notwithstanding that the surgeon to-day explores the biliary tract with care, every now and then a stone or stones are left behind. Sometimes there is a recurrence of symptoms in patients in whom the bile passages are known to have been cleared

CURRENT NOTES.

The Indian Medical Service

The promise made in response to the representations of the British Medical Association that the pay of the officers of the Indian Medical Service should be increased by 50 per cent. was in part fulfilled soon afterwards by the issue of a new scale for officers in military employment. A resolution of the Government of India fixing scales for officers in civil employment was, we are informed, published in India on March 3rd. The new scales, it is stated, were, in consultation with the Secretary of State, settled as long ago as February, 1920, and payments will be made with retrospective effect from January 1st, 1920. When the official text is received it will be carefully examined; judging from the account published in the *Pitner Mail* of March 11th, the provisions of the resolution are complicated.

Colonial Medical Services.

At its last meeting the Dominions Committee of the Association had again before it a large number of questions affecting the Colonial Medical Services. The Committee took strong exception to the delay on the part of the Colonial Office in dealing with the recommendations of the Departmental Committee, the report of which is dated as long ago as July 1st, 1920. In its reply to the Association of November 15th, 1920 (printed in the *SUPPLEMENT* of November 27th, 1920, p. 141), the Colonial Office stated that the report of the Departmental Committee had been transmitted to the Colonial Governments and that it was expected that the observations of the latter would be received in a few weeks. In these circumstances the Dominions Committee, on March 21st, drew the attention of the Colonial Office to the great uneasiness and dissatisfaction felt by the British Medical Association at the delay in dealing effectively with the recommendation contained in the report, and intimated to the Colonial Office that unless the Association received very definite and early assurance that the grievances complained of were being remedied, it would be impossible for the Association to refrain from active dissuasion of medical men who might be thinking of entering the Colonial Service. In a reply dated March 29th, the Colonial Office expressed regret that the expectation that the Colonial Governments would reply at an early date to the circular dispatch sending out the report of the Departmental Committee had not been fulfilled; that several replies had been received, but that some of the larger colonies had not yet answered, and that a telegraphic reminder had been sent to all whose opinion was likely to be of importance. The Colonial Office further stated that in one case it had been ascertained that the delay was due to the desire of the Governor to obtain a full and complete expression of

opinion from the Medical Department, and to the wish of the head of the Medical Department, in his turn, to ascertain the views of his subordinates; that the officers in question are scattered over a very large tract of country, and would naturally take time to consider and formulate their views on the report; that as soon as the replies are forthcoming from the more important colonies which have not yet answered, the whole question will be carefully considered; and that "the Secretary of State trusts that he will be able to arrive at a definite conclusion, at any rate on the main suggestions of the Committee, without further delay." The Association is now on the point of making further detailed representations to the Colonial Office. These will be reported in this column as soon as possible.

Annual Meeting at Newcastle: Radiology Section.

The Chairman of Council and the President-elect have invited Dr. Robert Knox to become President of the Section of Radiology and Electro-Therapeutics at the forthcoming Annual Meeting of the British Medical Association at Newcastle-on-Tyne, in place of the late Dr. W. Ironside Bruce, and Dr. Knox has accepted the post.

Mileage Fees for Pension Referees.

In February the Ministry of Pensions Subcommittee learned that the Ministry of Pensions was contemplating a reduction in the fees paid to medical referees in respect of mileage. A letter was sent to the Ministry pointing out that the proposed reduction was neither necessary nor reasonable, seeing that the cost of travelling was still very high. The Ministry of Pensions replied that the revised fees had been drawn up after due consideration of all the circumstances, and expressed regret that the suggestion made by the British Medical Association—that the old scale should be continued—could not be adopted. The chief reduction in the new scale of fees is that no fee is paid in respect of the first mile. It is understood that the new scale came into operation on March 1st, 1921. The Subcommittee has considered this reply and is of opinion that the matter cannot usefully be pressed further.

PAYING PATIENTS IN POOR LAW INFIRMARIES.

POLICY OF THE MINISTRY OF HEALTH.

The following communication from the Ministry of Health has been received by the Medical Secretary of the British Medical Association:

Ministry of Health, Whitehall, S.W.1.
April 2nd, 1921.

Sir,

I am directed by the Minister of Health to refer to Dr. Anderson's letter of the 5th ult. and the previous correspondence respecting the schemes in contemplation by the guardians of the *Manchester* and *West Derby Unions* for the admission of persons other than the sick poor to their institutions, and to state that, following upon the inquiries which have been made on the subject, the Minister has addressed to

each board of guardians a letter in the terms of that to the West Derby guardians, a copy of which is enclosed for the information of the British Medical Association.

I am, Sir, your obedient servant,
(Signed) H. H. TURNER.

The letter referred to in the above communication is as follows:

Ministry of Health, March 29th, 1921.

Sir,

The Minister of Health has given further consideration to the scheme described in your letter of the 28th ultimo for admitting paying patients to vacant beds in the guardians' institutions, and he has directed me to request you to lay before the guardians the following observations in regard to this scheme.

1. The Minister deplores the conditions which have arisen in Liverpool and elsewhere as a result of the shortage of hospital accommodation, and in his opinion the only solution of the problem which is likely to command general approval is to make the institutions at present controlled by the guardians available for the use of the community as a whole, but free from the restrictions and disabilities that are inseparable from the use of these institutions so long as they remain under the control of the Poor Law authorities.

2. At the same time the Minister recognizes that the scheme of the guardians is a sincere attempt to meet a grave need, and pending the complete reorganization of the health services of the country which the Government have in view, he would be most reluctant to place any obstacles in the way of any practical proposals which the guardians can bring forward as a temporary measure for alleviating the suffering caused by the shortage of hospital accommodation, and which it is within their legal competence to carry into effect.

3. The Minister feels bound, however, to inform the guardians that he is advised that there is no legal authority under which they are empowered:

(a) To hold themselves out as prepared to receive patients, without investigation of their circumstances, in consideration of an undertaking to pay a fixed weekly sum;

(b) to recover from or in respect of a patient a sum in excess of the actual cost of the relief given, or, on the other hand, to compound for the recovery of a fixed sum less than the actual cost of relief where the patient's means are sufficient to enable him to repay the whole of that cost; or

(c) to differentiate between patients as regards the accommodation provided for them, or as regards their treatment, nursing, dietary, etc., merely on the ground that repayment is being obtained.

4. Apart from the legal issues above mentioned, the Minister considers that in order to secure the fullest benefit consistent with reasonable economy from the operation of the scheme, it is essential that it should be carefully co-ordinated with other agencies for the provision of medical treatment; and with this object the local medical committee, if appointed, or other appointed representatives of the medical profession and the managers of the voluntary hospitals in the locality should be called by the guardians into consultation with them.

Among matters which might usefully form the subject of such consultation would be the kinds of cases, medically, that would be most suitable for admission, and amongst these the kinds, if any, as to which it is considered that on medical grounds priority might advisedly be given, and the kind of recommendation—for example, from a medical practitioner already in attendance, or from a hospital or other medical institution—which should be regarded as affording *prima facie* ground for admission. Other questions meriting consideration might be whether, in order to avoid waste from overlapping, any kind of division of function could be arranged between large general hospitals on the one hand and the guardians' infirmary on the other, and whether arrangements could be made whereby the medical teaching staff of the university could have access to the guardians' infirmary for purposes of medical education.

I am, Sir, your obedient servant,
(Signed) H. W. S. FRANCIS,
Assistant Secretary.

Association Notices.

SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH.

SCHOLARSHIPS.

THE Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows:

1. An ERNEST HART MEMORIAL SCHOLARSHIP, of the value of £200 per annum, for the study of some subject in the department of 'State Medicine.'

2. THREE RESEARCH SCHOLARSHIPS, each of the value of £150 per annum, for research into some subject relating to the Causation, Prevention, or Treatment of Disease.

Each scholarship is tenable for one year, commencing on October 1st, 1921. A Scholar may be reappointed for not more than two additional terms.

The Conditions of the award of Scholarships are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.2.

GRANTS.

The Council of the British Medical Association is also prepared to receive applications for Grants for the assistance of Research into the Causation, Treatment, or Prevention of Disease. Preference will be given, other things being equal, to members of the medical profession, and to applicants who propose as subjects of investigation problems directly related to practical medicine.

The Conditions of the award of Grants are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.2.

Applications.

Applications for Scholarships and Grants for the year 1921-22 must be made not later than Saturday, June 25th, 1921, in the prescribed form, a copy of which will be supplied by the Medical Secretary on application.

Each application should be accompanied by testimonials, including a recommendation from the head of the laboratory, if any, in which the applicant proposes to work, setting out the fitness of the candidate to conduct such work, and the probable value of the work to be undertaken. This is not intended, however, to prevent applications for Grants in aid of work which need not be performed in a recognized laboratory.

ELECTION OF COUNCIL OF ASSOCIATION, 1921-22.

A LIST of the Groups of Branches in the United Kingdom for election of twenty-four Members of the Council, 1921-22, and **Nomination Form**, were published in the SUPPLEMENT of March 12th (p. 73). The **Nominations** must be in the hands of the Medical Secretary **by May 16th**.

The result of the election for Members of Council by the Groups of the Oversea Branches was published in the SUPPLEMENT of February 19th, 1921.

ELECTION OF REPRESENTATIVE BODY OF ASSOCIATION, 1921-22.

Constituencies in Representative Body.

THE Council has finally grouped the **Home Divisions** for election of the Representative Body, 1921-22, in the same manner as for 1920-21, except that the Calthness and Sutherland Division of the Northern Counties of Scotland Branch, and the Rotherham and Sheffield Divisions of the Yorkshire Branch have been made independent Constituencies.

As intimated to all the **Oversea Bodies**, the Council has made each Oversea Division and Division-Branch an independent Constituency.

Election of Representatives and Deputy-Representatives.

THE REPRESENTATIVES AND DEPUTY-REPRESENTATIVES in the Representative Body must be elected **not later than June 17th**, and their names notified to the Medical Secretary **not later than June 24th**. The Annual Representative Meeting at Newcastle begins on July 15th.

Special attention is drawn to the fact that the election of Representative(s) and Deputy-Representative(s) may, at the discretion of the Constituency, be carried out by General Meeting of the Constituency, or by postal vote.

MOTIONS FOR ANNUAL REPRESENTATIVE MEETING, NEWCASTLE, JULY, 1921.

NOTICES OF MOTION by Divisions, Constituencies, or Branches, for the consideration of the Annual Representative Meeting of the Association, commencing Friday, July 15th, 1921, proposing to make any addition to, or any amendment, alteration, or repeal of, any Article or By-law, or to make any new Article or By-law, or proposing material alteration of the policy of the Association in matters relating to the honour and interests of the profession or of the Association, must be published in the BRITISH MEDICAL JOURNAL SUPPLEMENT not later than May 14th, and for this purpose should be received by the Medical Secretary **not later than April 30th**.

MEETINGS TO BE HELD.

DIVISION.—A meeting of the practitioners in East Sussex Albany Hotel, Hastings, on Friday, April 15th, at 4 p.m. Dr. Alfred Cox, Medical Secretary British Medical Association, will give an address entitled "How much more State medical service does the medical profession want?" The chair will be taken by Dr. J. D. Hessey. The address will be followed by questions and a discussion, to be opened by Dr. E. W. Skinner, J.P.

Meetings of Branches and Divisions.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.

The City Division held a dinner-dance at the Abercorn Rooms, Great Eastern Hotel, Liverpool Street, on March 31st. Over fifty members and friends attended, and a most successful evening was spent. It is intended to hold another similar function in December.

INSURANCE.

CORRESPONDENCE.

Dental Anaesthetics: Insurance Records.

SIR,—It is evident that there are misapprehensions still to be removed in spite of all official communications and of memoranda from the Insurance Acts' Committee sent to all Panel Committees and to every Insurance practitioner. It is curious that some doctors prefer the greater trouble of writing to the lesser trouble of reading.

Dr. W. G. Bennett will be glad to know that he will not, as an insurance practitioner, be compelled to attend his patients at the surgeries of dentists who may be newly qualified under the Dental Bill if it becomes an Act. Indeed, as an insurance practitioner he is not in any way concerned with dental treatment by a dentist old or new. Such treatment is not within the insurance contract, and therefore fees for anaesthetics required for such treatment are a purely private matter, and are not allowed to be paid from the medical pool. If Dr. Bennett has been sending in claims for such anaesthetics his claims should have been disallowed by his Panel Committee.

Dr. Howard Murphy is concerned as to his course of action in order to keep his records when, as he imagines, the envelopes are "sent each year to the Insurance Committee for statistical tables to be drawn up." He will be relieved to know that they have not to be sent up each year or at any other time; and if he will read the official instructions he will see that the contingency of having to keep some notes with regard to a patient for whom he is not at the time in possession of an official envelope has not been overlooked, and that the course of action in this contingency is definitely laid down.

I do not think that Dr. Murphy's suggestion that two separate sets of records should be required will commend itself to insurance practitioners in general, but he does draw attention to several minor points which merit attention. May I emphasize the request of the Insurance Acts Committee that practitioners and Panel Committees will send up within the next six weeks any practical suggestions for the improvement of the present record forms or of the procedure to be adopted in connexion with them, so that all such suggestions may be codified and submitted to the next Panel Conference? This will be helpful, whereas such resolutions as those of the London Panel Committee—that records are necessary but that the present ones should be discontinued—are not helpful in the least. Perhaps they are not intended to be.—I am, etc.,

Stroud Green, N., April 2nd.

H. B. BRACKENBURY.

LOCAL MEDICAL AND PANEL COMMITTEES.

LONDON.

At the last meeting of the London Panel Committee a report was presented by a deputation which waited recently on the Ministry of Health to discuss the question of surgery and waiting-room accommodation. The matter arose out of the action of the Insurance Committee in imposing a condition with respect to surgery accommodation upon practitioners who had applied for permission to include more than 3,000 insured persons on their lists. The representatives of the Ministry at the interview expressed the opinion that the question of surgery accommodation was a relevant circumstance in dealing with practitioners who had unusually large lists, and suggested that the Allocation Subcommittee, which is constituted partly of Insurance Committee representatives and Panel Committee representatives, was the proper body to deal in the first instance with all questions relating to surgery accommodation. This suggestion was agreed to, and the terms of reference of the

be widened accordingly. It appears to be inadequate for his will be made to him, and in the event of his refusal to comply with a reasonable request, the matter will be brought to the notice of the Insurance Committee.

A scheme has been drafted for the reconstitution of the Panel Committee. The chief features of the proposals are that members of the committee should be elected for three years, one-third to retire annually; and that representation should be based on the number of electors in each area (one representative for each thirty or part of thirty in every borough). Under the present arrangements some boroughs are inadequately represented and others over-represented.

INSURANCE COMMITTEES.

LONDON.

THE London Insurance Committee, on March 31st, passed a resolution to the effect that unless steps were taken to keep the Committee notified of changes of address by insured persons, it would be unable to keep up to date the list of persons for whose treatment each insurance practitioner was responsible, as required by the Medical Benefit Regulations, and, further, that in view of the large number of inaccuracies in the registers, due to the non-notification of changes of address, it was impracticable properly to carry out the clause of the allocation scheme relating to the assignment of insured persons to practitioners. A deputation is to bring the subject before the Minister of Health.

Lock-up Surgeries.—It was reported that the Minister of Health's attention had been drawn recently to cases, particularly in the East End of London, in which insurance practitioners resided at a considerable distance from their surgeries, and inadequate arrangements were made for the attendance of a deputy in the absence of the principal practitioner. The Committee was requested to investigate the matter. Inquiries have already proceeded. The full report is to be made when the Minister stated that he applied with special force when a practitioner was continuously absent from his practice and did not attend at the surgery, mere attendance during the restricted surgery hours was not in itself a complete fulfilment of the obligation to give personal service if during the remainder of the day and night the practitioner was not within reasonable call.

Range of Medical Service.—The Local Medical Committee having decided that an operation for the removal of haemorrhoids and an operation for the removal of cysts in the neighbourhood of the knee-joint were not such as could be properly undertaken by a general practitioner of ordinary professional competence and skill, the Medical Benefit Subcommittee of the Insurance Committee challenged this finding, and recommended to the Insurance Committee that it should intimate to the Ministry of Health its non-concurrence with this limitation upon the duties to be expected from an insurance practitioner. Mr. P. Rockcliffe urged that if it was true that certain insurance practitioners were not capable of performing these operations their capitation fee should be forfeited and given to the hospitals where the operations were in fact performed. After some discussion, in which the medical members protested against lay judgement in a professional matter, the chairman of the subcommittee took back the recommendation in order to enable his subcommittee to present it later in a more reasoned form. The opinion of the Local Medical Committee was arrived at on the grounds that an operation for haemorrhoids involved risk of both primary and secondary haemorrhage, and that the removal of cysts from the neighbourhood of the knee-joint involved perforation of the joint and consequent risk of sepsis.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

the Sandhurst. G. Christie to the Victoria additional for Haslar Hospital. J. H. Burdett to R.N. Hospital, Malta; Surgeon Lieutenant Commanders G. L. Ritchie, M.C., to the Osea. W. J. Gerrard to the Surprise; Surgeon Lieutenant G. Aubrey to the Ajax.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel T. L. Fielding, D.S.O., relinquishes the acting rank of Colonel.
Lieut.-Colonel A. R. O'Flaherty retires on retired pay.
Lieut.-Colonel N. Tjaek is placed on retired pay and is granted the rank of Colonel.
Major and Brevet Lieut.-Colonel F. W. Lamballe is placed on retired pay on account of ill health caused by military service.
Major W. Byam, O.B.E., relinquishes the temporary rank of Lieut.-Colonel on reduction of establishment.
Temporary Major E. H. Marshall (Major R.H. and R.F.A.T.F.) relinquishes his temporary commission.
Captain R. G. Shaw, M.C., to be acting Major from November 21st, 1921, to June 4th, 1922.

Captain A. B. H. Bridges, O.B.E., is restored to the establishment. To be Captains: Temporary Captain A. S. Plant, M.C., with seniority, February 4th, 1918, and precedence next below R. C. Aitchison; Captain S. O. Dolan from R.A.M.C.(T.F.), with seniority August 16th, 1918, and precedence next below C. F. Anthonisz; Captain F. McKibbin, from R.A.M.C.(S.R.), with seniority September 25th, 1918, and precedence next below F. A. L'Estrange.
P. J. Serlingour, O.B.E., relinquishes the local rank of Major, July 10th, 1919 (substituted for notification in the *London Gazette*, November 22nd, 1920).

Temporary Lieutenant H. P. Hodge to be temporary Captain. The following relinquish their commissions: Temporary Lieut.-Colonels and retain the rank of Lieutenant-Colonel: P. C. E. Tribe, O.B.E., Ernest W. White. Temporary Captains and retain the rank of Captain: C. L. de Zylva, on ceasing to serve with the Ceylon Sanitary Company; P. Kitchin A. Cowes, Arthur G. Leitich.

ROYAL AIR FORCE.

MEDICAL BRANCH.

The following are granted temporary commissions in the ranks stated, with effect from and with seniority of the dates indicated: Flight Lieutenants: C. W. T. Baldwin (March 24th), D. Le Has and W. R. Keith (April 1st). Flying Officers: F. T. Allen (March 29th), J. A. Perdrau (April 1st).

INDIAN MEDICAL SERVICE.

Lieut.-Colonel W. R. Battye, D.S.O., has been posted as Administrative Medical Officer in Central India and Agency Surgeon, Southern States of Central India.

Major G. D. Franklin, O.B.E., has been posted as Residency Surgeon, Indore.

Colonel T. Stodart, M.B., has been permitted to retire from the service (January 13th, 1921).

Major-General W. R. Edwards, C.B., C.M.G., R.H.P., Director-General, has been granted privilege leave for six months, March 15th, 1921.

Major-General W. H. B. Robinson, C.B., Surgeon-General with the Government of Bengal, has been appointed to officiate as Director-General, with effect from the date on which he assumes charge of that office.

Lieut.-Colonel W. H. Dickinson, Officiating Chemical Examiner, Bengal, and Professor of Chemistry, Medical College, Calcutta, has been granted, with effect from February 1st, combined leave for twelve months.

Colonel J. Garvie, K.H.S., Inspector-General of Civil Hospitals and Prisons, Assam, has been granted, with effect from March 20th, combined leave for eight months.

Lieut.-Colonel R. H. Deane, Principal and Professor of Medicine, Medical College, Calcutta, and First Physician to the College Hospitals, has been appointed to officiate as Inspector-General of Civil Hospitals and Prisons, Assam.

The services of Captain C. Newcombe, M.B., have been placed permanently at the disposal of the Government of Madras (December 4th, 1920).

Major R. T. D. MacGregor, Medical Officer, His Britannic Majesty's Consulate for Sistan and Kain, is appointed to officiate as His Britannic Majesty's Consul for Sistan and Kain in addition to his own duties (January 17th).

Lieut.-Colonel F. A. Smith has been posted as Residency Surgeon at (s).

Officers have been permitted to retire from the service on the dates specified: Colonel W. M. Moleworth, C.I.E., C.B.E., V.H.S. (January 22nd), Lieut.-Colonels C. Donovan and J. M. Crawford, O.B.E. (February 1st), Lieut.-Colonel W. B. Lane, C.I.E., C.B.E. (February 8th).

Major R. B. Seymour Sewell, Surgeon-Naturalist Marine Survey of India, has been granted, with effect from September 1st, 1920, thirteen months' combined leave.

Colonel C. R. M. (s) Civil Hospitals, Central Provinces, has been permitted to retire from the service on February 25th.

Lieut.-Colonel P. (s) Surgeon, Nagpur, has been appointed to officiate as Inspector-General of Civil Hospitals, C. (s) Provinces with effect from the date on which he assumes

C.I.E., Surgeon-Superintendent General Hospital, Calcutta, has been appointed to officiate as Surgeon-General with the (s) of Bengal (March 15th).

Major (s) F. P. Connor, D.S.O., Professor of ry, Medical College, Calcutta, and has been granted, with effect from (s) or eight months.

Major H. B. Steen, M (s) Clinical and Operative to the College Hospital

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel H. L. de Lech, T.D., resigns his commission and retains the rank of Lieutenant-Colonel, with permission to wear the prescribed uniform.

Captain H. J. G. Wells, R.A.M.C., to be Adjutant of the R.A.M.C. School of Instruction, West Riding Division.

Captain R. Ellis resigns his commission, and is granted the rank of Major.

Captain A. M. Baillie resigns his commission and retains the rank of Captain.

Captains to be Majors: S. F. St. J. Steadman, H. K. Griffith.

Captain J. G. Cooke resigns his commission, and is granted the rank of Major.

Captain D. R. E. Roberts (late R.A.M.C.) to be Captain, with precedence as from April 10th, 1918.

Lieutenant J. F. O'Grady to be Captain.

J. A. I. London to be Lieutenant.

2nd London Sanitary Company.—Captain F. S. Carson, M.C., resigns his commission and retains the rank of Captain.

5th Southern General Hospital.—Captain C. H. Cowen resigns his commission and is granted the rank of Major.

Supernumerary for Service with the O.T.C.—Captain H. Emerson, M.C., to be Major.

Sanitary Service.—Major R. A. Farrar is restored to the establishment on ceasing to be employed under the Colonial Office.

DIARY OF SOCIETIES AND LECTURES.

HARVEIAN SOCIETY, Town Hall, Paddington Green, W.—Thurs., 8.30 p.m., Mr. D. C. L. Fitzwilliams, C.M.G.: Naevi of Children and their Treatment.

HUNTERIAN SOCIETY, St. George's College, Lambeth, E.C.—Wed. 9 p.m., Discussion on the Treatment of Syphilis. To be opened by Mr. J. E. R. McDonagh.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tues. and Thurs., 5 p.m., Oliver Sharpey Lectures by Dr. Thomas Lewis, C.B.E., F.R.S.: Observations upon the Nature of Auricular Flutter and Fibrillation.

ROYAL SOCIETY OF MEDICINE.—Mon., 5 p.m., Demonstration of Lantern Slides in natural colours of dermatological and other medical subjects. Tues., 5 p.m., General Meeting of Lectures. War Section: Mon., 5.30 p.m., Surgeon-Commander S. F. Dudley, R.N.: Influenza Epidemic in the Royal Navy. Section of Surgery, Subsection of Proctology: Wed., 5 p.m., Discussion on Prunella Ani, to be opened by Mr. Lockhart-Mummery and Sir Charles Gordon-Watson. Section of Otolaryngology: Thurs., 5 p.m., Mr. T. B. Layton and Mr. A. Ryland: Quantitative Estimation of Hearing; Unilateral Deafness. Mr. F. J. Cleminson: Sinusitis in Children. Cases will be shown by Dr. Macleod and Mr. Keen. Demonstration at the Aural Clinic of the Leicester Education Committee.

St. John's Hospital, 49, Leicester Square, W.C.—Thurs., 6 p.m., Chesterfield Lecture by Dr. W. Griffith: Treatment of Skin Diseases.

SOCIETY FOR THE STUDY OF INTOXICATION, 11, Chandos Street, W.1.—Thurs., 4 p.m., Discussion on the Use of Alcohol in Medicine. To be introduced by Dr. H. H. Dale, O.B.E., F.R.S.

British Medical Association.

OFFICES AND LIBRARY, 419, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals and standard works can be consulted, is open to member from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS (Financial Secretary and Business Manager, Telegrams: Articulate, Westrand, London). MEDICAL SECRETARY (Telegrams: Medisecra, Westrand, London). APRIL.

15 Fri. London: Standing Subcommittee of Central Ethical Committee, 2.30 p.m.

Hastings Division, Albany Hotel, Hastings, 4 p.m.: Address by Dr. Alfred Cox on "How much more State medical service does the medical profession want?"

20 Wed. London: Council, 10 a.m.

POST-GRADUATE COURSES AND LECTURES.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION, The Infirmary, Wed., 4.15 p.m., Eye Cases.

MANCHESTER ROYAL INFIRMARY.—Thurs., 4.30 p.m., Mr. F. H. Westmacott: Suppuration in the Accessory Cavities of the Nose.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Daily, 10 a.m. (and 2.30 p.m. Tues.), Ward Visits; 2 p.m., In- and Out-patient Clinics and Operations.

APPOINTMENTS.

BERRY, William A., M.D., D.P.H., Medical Officer of Health for the City of Bloemfontein, O.F.S.

BROWNLEE, W. Barrie, M.D. Glas., F.R.C.S.E., Ophthalmic Specialist to County Court Circuit No. 4.

MILTON, J. Penn, M.R.C.S., L.R.C.P. Lond., Medical Superintendent to the Darvell Hall Sanatorium of the East Sussex County Council.

REDDEL, James W. G. H., M.C., M.B., Ch.B., F.R.C.S. Edin., Major R.A.M.C. (R. of O.), Assistant Surgeon, South Devon and East Cornwall Hospital, Plymouth.

ROBINSON, William, M.B., Ch.B. Leeds, Superintendent of the Breckwood Mental Hospital.

YOUNG, Gavin, M.C., M.B., Ch.B. Glas., F.R.F.P.S.G., Assistant Surgeon to the Throat and Nose Department, Western Infirmary of Glasgow.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH.

WILLIAMS.—On the 30th March, at Wednesfield, to F. S. Williams M.B., B.S. Lond., and Mrs. Williams—a son.

previously. Such cases always raise the question as to whether a stone can form anew, from nothing as it were, within the common and hepatic ducts. In many recurrences the possibility cannot be excluded that a stone may have wandered up into the intra-hepatic pathways and so been overlooked. But when, after the finding and removal of such a calculus, symptoms of cholelithiasis come back again and yet again, the idea arises that the stones have been recreated in the bile ducts. It is known that these last are not pre-eminently the birthplaces of stones, which as a rule form within the gall bladder, and there are those in whom this belief is so strong that they would deny that a biliary calculus can arise elsewhere. It must be admitted that the most skilled surgeon after an exemplary search may fail to discover a calculus lodged within a small branch of the duct system within the liver substance, and that this calculus may later wander into a large duct and then be obvious to all.

This problem has been discussed by Deaver,² by Judd,³ by Eisendrath,⁴ and quite recently by Emerson Brewer.⁵ Judd's figures from the Mayo clinic include 219 secondary operations on gall-stone cases. Eighty per cent. of these were for removal of a previously drained gall bladder. In six cases stones had to be removed from the common duct after a precedent cholecystectomy. In one case Judd removed a large stone from the common duct on three separate occasions, the gall bladder having been excised at the first sitting. Brewer's cases are of great interest. A woman had a cholecystostomy performed in 1911. Eighteen months later stones were removed from the common duct and the gall bladder excised. After a similar period of time trouble recurred and several large dark brown stones were found in the common duct. The duct system was explored by finger and probe well within the liver substance and left clear. Eight months later a fourth operation was undertaken and seven stones were scooped out, three high up in the hepatic ducts, well within the liver. One and a half years later a fifth operation was done and two or three stones removed. Experiences such as these point strongly towards the new formation of duct calculi. Unfortunately, Brewer does not give an account of the minute structure of the stones. Pigment calculi are the most likely to form without the agency of the gall bladder mucosa.

Lastly, in connexion with this subject reference must be made to Lewisohn's⁶ interesting case of intra-hepatic cholelithiasis. Here stones within the liver parenchyma perforated through it and caused local peritonitis. Again, stricture of the duct and periductal adhesions are causes of persistent trouble which must not be forgotten.

THE FIRST MINISTER OF HEALTH.

DR. CHRISTOPHER ADDISON will always be remembered in the history of health and public health in this country if only because, as President of the Local Government Board, he carried through the bill by which the Ministry of Health was established. The bill, in its general structure, was well conceived, and met the wishes expressed by the British Medical Association and other medical organizations. It was in accordance with expectation that Dr. Addison

became the first Minister of Health. The Ministry came into existence on July 1st, 1919; to it were transferred all the powers and duties of the Local Government Board, together with those of the Insurance Commissioners for England and Wales. Other powers were to be transferred to it, but, as things stood, the task before the new Ministry was gigantic; it had to satisfy the expectations for better health conditions of the medical profession and the public generally, and, in particular, it had to attempt to make good the serious deficiency in housing, a deficiency which had been considerable before the war and had been greatly increased by the almost complete suspension of building during its progress. Obviously housing is of first importance in all health questions, but it is unfortunate that so much of the energy of the Minister had to be given up to this one subject, that so many obstacles—some of them unnecessary—were thrown in his way, and that he so early lost the services of Sir John Anderson, who had been specially selected to be second secretary of the Ministry in charge of housing. It is unfortunate also that the Ministry so early lost the services of a great public servant—one intimately acquainted with the more strictly medical side of its work and eager for its extension—by the death of Sir Robert Morant in March, 1920. At the beginning of that month Dr. Addison, in a review of the administrative action of the Ministry, gave some account of what had been undertaken in matters directly affecting health. He referred in particular to the strengthening of the powers of port sanitary authorities and to the multiplication of child welfare and midwifery centres, and mentioned some of the improvements it was intended to introduce into the insurance service. During last session the bill to remove sanatorium benefits from the National Insurance scheme and to place the treatment, other than domiciliary, of tuberculosis within the province of the local authorities was passed.

Commenting on the situation at the end of last May we observed that the hardest worked of all Government departments was the Ministry of Health, and asked for the sympathy and encouragement which its energetic efforts deserved. The subsequent history of the Ministry was not fortunate, and we cannot doubt that, as we pointed out at the time, Dr. Addison's position was seriously compromised by the introduction into an omnibus bill last autumn of legislation profoundly affecting the constitution of general hospitals. The mistake was seized upon by a certain section of the press, anxious, as we must suppose, to attack Mr. Lloyd George through his consistent supporter, Dr. Addison. Dr. Addison remains a Cabinet Minister, but we should have preferred to see him still at the Ministry of Health. It was a very great advantage in the early days of that Ministry to have a man who was by his training well aware of the professional outlook and ready, as on several occasions he showed, to attach due weight to the advice and criticisms of the profession. It would have been an advantage had he continued to be head of the Ministry now that some of the difficulties—we had almost said the artificial difficulties—the Ministry has encountered have been got out of the way.

THE ANNUAL MEETING AT NEWCASTLE.

THE details of the programme for the Annual Meeting at Newcastle-upon-Tyne are being gradually settled. The Representative Meeting will begin on Friday, July 15th, at 10 a.m., and will be continued on Saturday, Monday and Tuesday. On the latter day the statutory Annual General Meeting will be opened at 2 p.m., and will be resumed at

² Deaver. "Recurrence of Gall Stones," *Surg., Gynec. and Obstet.*, 25, 1917.

³ Judd. "Recurrence of Symptoms following Operations on the Biliary Tract," *Ann. Surg.*, April 1918.

⁴ Eisendrath. "Recurrence after Operations on the Biliary Passages," *J. Amer. Med. Assoc.*, 1917, ix, p. 1752.

⁵ Brewer. "Recurrence of Calculi in Common and Hepatic Ducts after Cholecystectomy," *Arch. of Surg.*, January, 1921, p. 145.

⁶ Lewisohn. "Intrahepatic Cholelithiasis," *Ann. Surg.*, May, 1916.

8 p.m., when the incoming President, Professor David Drummond, C.B.E., will give his address; it will be followed by a reception in the Grand Assembly Rooms at 10 p.m., with the President and Mrs. Drummond as hosts. The Sectional Meetings begin on Wednesday, July 20th. The scientific work is to be dealt with in seventeen sections, of which five meet on each of the three days. Proctology and Urology are separate units this year; and each will hold a one-day session; this is a new departure which, it is hoped, will give an opportunity for useful discussion along special lines. The dates on which the several two-day and one-day sections will meet were announced in a Current Note in last week's SUPPLEMENT. The names of the officers of the various sections were announced in the SUPPLEMENT of March 5th, and those desirous of taking part in the work of any special section are invited to communicate direct with the honorary secretaries, whose addresses were there given. A special effort is being made to encourage interest in the afternoon demonstrations, which were very numerous attended at Cambridge last year. They are more informal than the morning sessions, and actual cases, specimens, apparatus, etc., are shown and discussed. At 8 p.m. on Wednesday, July 20th, there will be a Special Address in Industrial Medicine, by Sir Thomas Oliver, and on Friday, July 22nd, at 7.30 p.m., Professor Arthur Keith will deliver the popular lecture in the King's Hall of Armstrong College on "Evolutionary wounds, their healing, and the part they play in the evolution of the human body." The social arrangements already planned include, in addition to the President's reception, a garden party in Jesmond Dene, when the Association will be the guests of the Lord Mayor, an evening reception by the Branch Council, to be followed by a dance; and other evening parties at which dances have also been arranged.

R.A.M.C. WAR MEMORIAL.

SUBSCRIPTIONS in response to the appeal for funds to establish a war memorial to the officers and men of the R.A.M.C. who lost their lives in the war amount to about £19,500. Of this, £1,500 was ear-marked by the donors for the benefit of families and dependants, and at a meeting of the general committee, held recently under the chairmanship of Sir Alfred Keogh, it was decided that it should be divided between the R.A.M.C. Regular and Auxiliary Funds in proportions to be decided after the wishes of the committees at Portsmouth and Netley had been ascertained. The amount available for the purposes of the memorial itself will, it is anticipated, be, in round figures, £18,000. The proposal made to the meeting and eventually adopted by it unanimously was of a novel character, and will, we believe, commend itself to the Corps and to the medical profession generally. It has three parts: the first is to erect in Westminster Abbey, on the wall in a suitable position near the grave of the Unknown Warrior, a tablet commemorating the memory of the officers and men of the R.A.M.C., Regular, Territorial, and Temporary, who fell or died in the war; the second is that a list of their names should be inscribed on a "Golden Book" kept permanently in the Chapter House of the Abbey; and the third that a contribution should be made to the fund for the restoration of the Abbey. It was at first suggested that some definite concrete part of the restoration, such as the embellishment of a chapel, should be undertaken, but the Dean and Chapter, after consideration, found that the nature of the work being done was such that it was difficult, and in fact impossible, to set apart any particular section; it was accordingly decided to give the sum of £10,000 to the Abbey Restoration Fund and that the gift should be recorded on the memorial tablet. The Dean and Chapter entered cordially into the project for the permanent preservation of the "Golden Book" and for the erection of the tablet. The Director-General, vice-

chairman of the committee, read the correspondence he had had with the Dean, and stated that when the proposal was placed before the Colonel-in-Chief of the Corps, Field Marshal the Duke of Connaught, he had shown himself most sympathetic and appreciative. The proposal, which it was understood originated with Colonel C. R. Tyrrell, C.B., C.B.E., R.A.M.C.(ret.), was commended by Sir Norman Moore, President of the Royal College of Physicians, by Sir Arthur Sloggett, and Sir Launcelette Gubbins. Sir Anthony Bowlby, President of the Royal College of Surgeons of England, who was unable to be present at the meeting, has also expressed his entire approval. It was decided that photographs of the tablet, together with a plan of the Abbey showing its position, should be sent to the relatives of each person mentioned in the Golden Book, and that replicas of the memorial tablet should be given to Edinburgh and Dublin. The production of the book would, it is estimated, cost between £3,000 and £4,000. The tablet, with replicas, will cost a considerable sum, but it is not yet possible to specify the exact amount. An Executive Committee to carry out the proposals was appointed, consisting of the Director-General (chairman), Sir Norman Moore, Bt., Major-General Sir W. G. Macpherson, Sir Launcelette Gubbins, Staff Sergeant Walton (members), and Colonel Tyrrell and Major E. B. Waggett, D.S.O., R.A.M.C.(T.F.), (joint secretaries).

RESEARCH IN RADIOLOGY.

LAST week (p. 500) the necessity for the provision of research facilities on a large scale into the properties of radium and x rays was discussed, and the present opportunities for research such as are afforded at the Radium Institute and the Middlesex Hospital were mentioned. Much of the increased opportunity for research work in radio-therapy that exists at present has arisen through the Medical Research Council, which has obtained from the Disposal Board of the Ministry of Munitions the use for a period of years of a large quantity of active radium salt for research purposes. The radium was collected from various parts of a great variety of war implements, and is of the estimated value of £72,500. The Council has prepared a scheme for the assignment of various fractions of this radium to selected centres of work where the results of its use can be adequately studied. Hitherto the opportunities of inquiry have been limited by the high cost of radium, and there has been little systematic and comprehensive study of its curative properties. There is evidence, the Council observes in its annual report for 1920, that radium used ignorantly or in improper exposures—whether too large or too small—may accelerate death instead of preventing or delaying it, and that in particular the onset of secondary malignant growths may be hastened or actually caused by unsuitable radium treatment of the primary growth. Without close study, and without the collection of adequate contemporary and later records, for which at many of the centres of work sufficient opportunity has not hitherto been found, it is impossible for these grave dangers to be detected or avoided. The Council has assigned radium fractions to a number of centres, in London, to University College Hospital, St. Bartholomew's Hospital, the Middlesex Hospital, King's College Hospital, and the Radium Institute; in Birmingham, to the General Hospital; in Dublin, to the Council for Public Health for Ireland; negotiations with other centres have been opened. Much of the research carried on during 1919 under the auspices of the Medical Research Council was conducted at the Middlesex Hospital, where elaborate precautions were taken to protect laboratory workers and nurses from the physiological effects of so large a quantity of radium; the radium, which was in the form of the bromide, was contained in eighteen tubes, which were kept in a circular brass box placed in the centre of a cubical box of lead, each edge of which measured 20 in. This leaden cube, weighing one

ton and a half, was enclosed within an iron safe as far away as possible from rooms in daily occupation. The radium box itself was never directly handled, but was moved from place to place as required by means of a "long arm" and a special lead-protected trolley; the treatment of patients was carried out in a separate room, with the aid of lead-screened apparatus. All this special apparatus was provided by the Medical Research Council. During this early stage of the investigation over one hundred patients were treated. Of these the great majority were inoperable, but prophylactic doses were given in four cases of operable carcinoma before operation. Four cases of cancer of the breast, inoperable before massive radium treatment, were subsequently considered by the surgeon to have become operable, and underwent a "complete" operation. No conclusions could be drawn from these early cases, but a remarkable diminution in the size of the tumour in cases of lymphosarcoma and lympho-adenoma was observed. Microscopical examination of bone marrow in rabbits submitted to radiation, carried out by Dr. Price Jones in Professor Boycott's laboratory at University College Hospital Medical School, showed that the behaviour of lymphosarcoma was closely paralleled by the destruction of leucocytes in the blood, spleen, and lymphatic glands of animals. The experiments on rabbits and other animals exhibited in a striking way the selective action of the rays upon particular organs of the body or particular parts. The whole of the material from the animal and human cases has not yet been examined, but microscopical examination of the brains of the animals is being made by Sir Frederick Mott in his laboratory at the Maudsley Hospital. Investigations with α rays have an immediate bearing upon problems of radium treatment, and the experiments regarding the general effects of small doses of α rays upon animals have been continued on behalf of the Council by Professor S. Russ and his colleagues at the Middlesex Hospital. Facilities were given also to Professor Sir William Bragg, of University College, for experiments in the direction of standardizing the radium radiation against that of a Coolidge tube running under known conditions. All these investigations must have a fundamental value in guiding administrations of α rays to patients.

ROYAL NAVAL DENTAL SERVICE.

THE new regulations governing entry into the Royal Naval Dental Service, which have just been issued, suggest that the Admiralty desires to place this newly formed branch of the service upon a sound basis. The neglect of the teeth of the personnel of the navy has been at least as bad as the neglect of the teeth among the population in general. It was only in 1892 that the first attempt was made, at Haslar, to pay any attention whatever to dentistry in the navy, and it was not until the second year of the war that the first naval dentists were commissioned as officers of the R.N.V.R. After the war was over, the nucleus of a permanent dental service for the navy was formed, and its future now depends upon the response made to the invitation conveyed in the new regulations by the young qualified dentists of the country. The qualifications for admission to the dental service are very similar to those for the medical service of the navy: A candidate must be of British birth, of sound physique, ready to engage for general service at home or abroad, and be registered under the Dentists Act. The dean, or other responsible authority, of his dental school will be requested to render a confidential report on his character and professional ability, and, after an entrance examination, which will be held twice a year, successful candidates will enter the service arranged in order of merit. Should it at any time be considered expedient to grant commissions beyond those periodically competed for, the Admiralty takes power to admit annually two candidates specially recommended by the governing bodies of such

Dominion or Colonial dental centres as may be selected, on condition that they pass a qualifying test. Before a successful candidate is given a commission as Surgeon Lieutenant (D) in the Royal Navy he will be required to pass through a course of one month as decided upon by the Admiralty, and his commission will be confirmed on passing the qualifying examination at the end of this course. The subjects for the entrance examination will embrace dental surgery, including dental pathology and therapeutics, oral hygiene and oral prosthetics; candidates must obtain at least 50 per cent. of marks in each subject. A post-graduate course of three months' duration will be allowed to Surgeon Lieutenant Commanders (D) of over two years' seniority, and the officers going through this course will be accommodated at the Royal Naval College, Greenwich. This post-graduate course is designed to afford senior officers the opportunity of refreshing their general knowledge of dental surgery and making themselves familiar with modern advances. Their status in the navy is designed to be good, and "dental officers will select their cabins (all ward-room officers make such selection in order) according to their rank and seniority." The dental officer on a ship will be responsible directly to the captain. Surgeon Lieutenants (D) will receive as pay from £401 to £492; Surgeon Lieutenant Commanders (D), £593 to £730; and a Surgeon Commander (D), £775 to £912. There are to be forty-eight officers of the Royal Naval Dental Service, but of these only one can hold the rank of Surgeon Commander (D). As the service is only now at its beginning it is clearly very possible that the first officer to hold the rank of surgeon commander may retain his post for many years, thus blocking promotion absolutely. If the work of the dental service is to be carried out in the manner that everyone hopes, it is sufficiently important for an officer of the rank of surgeon commander to be stationed at each of the larger naval depôts, and at Haslar. In this way the risk of the service becoming rather a blind alley form of employment would be avoided.

INTERNATIONAL RED CROSS CONFERENCE.

THE first session of the tenth International Red Cross Conference, which assembled in Geneva on March 30th, was occupied in listening to an interesting address by the president, M. Ador, and in the appointment of committees. It was decided that following the precedent of the League of Nations, the Red Cross Society of a British Dominion should be admitted to the conference on an equal footing with those of other countries, and that similar recognition should be accorded to the Red Cross Society of the Netherlands Indies. Including those of Canada, South Africa, Australia, New Zealand, India and the Netherlands Indies, thirty-six Red Cross societies were represented; among them were the Red Cross societies of Germany and Austria, and the Red Crescent of Turkey; representatives of the Papal Government, of the League of Nations, of the International Labour Office, and certain societies, including the newly formed International Union for helping children, were also present. Neither the French nor the Belgian Red Cross was represented, because there are questions still open between the Governments of these two countries and Germany, and because both France and Belgium desire an assurance, described by the President of the Conference as very legitimate, that doctrines which during the war led to systematic violations of the Geneva Convention, would be disavowed. The French Red Cross, however, sent reports to this conference and expressed the hope that it might be able to be represented at the eleventh, as it had been at the ninth, held in Washington in 1912. At the second full session it was decided, on the motion of Mr. R. B. Bennett, K.C., representative of the Canadian Red Cross Society, to appoint a committee to report on the violations of the Geneva Convention committed during the war, in order that those guilty of such violations should be arraigned at the bar of

public opinion. Other commissions were appointed to prepare reports on the revision of the Geneva Convention, on the position of the Red Cross in civil war, and on the relation of Red Cross societies to Governments and to philanthropic associations. It will be remembered that a League of Red Cross Societies was organized in May, 1919, and that shortly afterwards its headquarters were established in Geneva, with Lieut.-General Sir David Henderson as Director-General. The president of the international conference was able to announce at its third meeting, on April 1st, that he and Sir David Henderson had come to an understanding with regard to the work of the International Committee of Red Cross Societies and the League of Red Cross Societies, and that this understanding had been ratified by both bodies. The Italian representative moved a resolution to issue an appeal to all the nations, calling upon them to combat the war spirit which still persists throughout the world. The resolution was supported by Dr. Livingstone Farrand, the representative of the United States, and by the representatives of Greece and Persia; it was carried unanimously. Throughout the discussions in the conference many references were made to the work which Red Cross societies can do during peace. Most of the detailed work of the conference was done by the special committees appointed, and the reports of these will not as a rule be available for some time. It is to be noted, however, that the committee on the limitation of war early arrived at certain resolutions forbidding the bombardment of open undefended towns, the deportation of the civil population, and the use of poison gases. An exhibition held during the conference included displays by the Red Cross societies of Italy, America, Sweden and Norway, and also by the Turkish and German societies.

HYGIENE OF SEAMEN.

Dr. G. S. BUCHANAN, in his address on the International Health Organization to be established at Geneva in connexion with the League of Nations,¹ expressed the hope that the organization would provide a means by which competent sanitarians would take their proper part in the international regulations of matters like ship ventilation, the construction of crews' quarters, and facilities for cleansing, and also as to rations—subjects to which the International Labour Office has begun to give attention. The Town Council of Newport, Monmouthshire, in its capacity as a port sanitary authority, has issued a report, in which it expresses the opinion that the British regulations for the hygiene of crews' quarters stand in need of immediate revision. During the war the agreements between the Controllor of Shipping and those interested in the provision of better accommodation for the Merchant Service led to considerable improvements in standard ships; the report alleges that the improvements were not general and that they have not been maintained in recent vessels built for British firms. The conditions of living on vessels registered under the American flag are said to be so much better that many of the best British sailors and firemen are seeking service in American in preference to British merchant vessels. While it is admitted that many British shipowners have provided greatly improved accommodation in recent years, it is alleged that others have failed to do so. Valuable opportunities of effecting improvements in the large number of new vessels built during the last three years have been lost, and the suggestion is made that a committee should be appointed to advise the British Government as to the changes that should be made in the regulations so that this country may go to an international congress with clean hands. The proposed committee, it is thought, should contain representatives of the Board

of Trade, the Ministry of Health, shipowners, shipbuilders, officers and men of the Merchant Service, port sanitary authorities, and the Admiralty. The question of accommodation for crews on board ship is beset with many difficulties, and can only be settled in a satisfactory manner by the frank recognition of certain basic principles which govern those conditions on board merchant ships. Sanitary methods suitable for houses on shore are not directly applicable to ships. Limitation of space in a ship must in the end influence all questions of hygiene at sea. A ship is the result of innumerable compromises between all the departments of the vessel, and any serious encroachment on space in favour of one particular department may increase expenditure to an extent the industry will be unable to bear. As it is, it is not easy to run a passenger ship at a profit, and drastic legislation may easily result in a large number of ships being laid up. Such statistics as are available do not point to any serious ill health on board ship. The rate of mortality from disease of European seamen on board steamships is 3.5 per 1,000 and that for lascars 5.4 per 1,000; these figures are below those in industrial life on shore for the same ages. As to the incidence of disease, no statistics have ever been published, and the only records available exist in the archives of those companies that have paid attention to the subject. It can, however, be stated that these records do not reveal any startling incidence of disease. It is undoubtedly desirable to ascertain the experience of medical officers of the various port sanitary authorities, but it should not be forgotten that they for the most part see only one side of the question—namely, that concerned with infectious disease—and it is to be hoped that in any attempt to grapple with this question use will be made of the experience of those who have been responsible for the health of seamen employed by the various companies. The subject has an international side; a large number of vessels change their nationality in course of time, many of them soon after completion, and an international standard of hygiene is therefore necessary. It is, of course, recognized that international agreement is necessary in dealing with the possible importation of exotic diseases, such as cholera, yellow fever, and plague. It is important, however, that international arrangements should be susceptible of revision without long delay such as ordinary Foreign Office methods usually entail. Dr. Buchanan's suggestions for short-circuiting the chancelleries—that is to say, the Foreign Offices of this and other countries—appear to us to be among the most valuable yet made.

LABELLING OF SKIMMED CONDENSED MILK.

THE Food and Drugs Act, 1899, imposes a heavy penalty upon the importation of condensed separated or skimmed milk except in tins or other receptacles which are specifically labelled and the words "separated" or "skimmed" printed in large and legible type. A fine may also be imposed upon a tradesman who sells such milk which is not so labelled. It is to be regretted that the qualification "large and legible" is so indefinite that it may be interpreted according to the desires of the interpreter. Even though there might be some difficulty in following the Margarine Act and defining the actual size of the type to be used, it would be quite simple to require that the type employed for the particular word or phrase should not be smaller than that used in any other part of the label. It is not so much the actual but the relative size of the type that is of importance. We have been led to refer to this matter as we have reason to believe that there are some brands of skimmed condensed milk the tins of which are so labelled as to mislead the purchaser although the law may be strictly carried out. A mother, therefore, may be giving her child milk which she believes to be unskimmed but which has had abstracted from it all but about 0.2 per cent. of its fat. At the instigation of Dr. Walter Bawell

¹BRITISH MEDICAL JOURNAL, March 5th, 1921, p. 531.

this question has, we learn, been under the consideration of the Health Committee of the Newport (Mon.) Corporation, and the seriousness of the position has been brought to the notice of the Ministry of Health.

SPELLING OF CHEMICAL TERMS.

THE progress of chemical inquiry, which is constantly bringing to knowledge new substances and new theories as to the constitution and relations of various classes of substances, is apt to cause confusion in nomenclature, especially in spelling. The Chemical Society, which publishes abstracts of chemical papers published elsewhere than in its *Transactions*, and is therefore among the first to feel the inconveniences which arise, issued a short time ago instructions to abstractors, which included directions with regard to spelling of certain classes of chemical compounds. It is directed that basic substances should invariably be indicated by names ending in *-ine*—as aniline, not anilin. This is in accordance with the practice of the *British Pharmacopoeia*, where alkaloids have a final "e," as morphine, strychnine. The Chemical Society directs that the termination *-in* should be restricted to certain neutral compounds, such as glycerides, glucosides, bitter principles, and proteins—as, for example, palmitin, amygdalin, albumin. This rule applies to vitamin, which should be so spelt—that is, without the terminal "e." It is further directed that compounds of basic substances with hydrogen chloride, bromide, or iodide should always receive names ending in *-ide* and not *-ate*, as morphine hydrochloride and not morphine hydrochlorate. This rule is, we believe, now generally followed in medical writings. Another rule relates to hydroxyl derivatives of hydrocarbons, which should be designated by names ending in *-ol*. Alcohols should be spoken of as mono-, di-, tri-, or *n*-hydric, according to the number of OH groups. Compounds which are not alcohols, but for which names ending in *-ol* have been used, are to be represented by names ending in *-ole*, if a systematic name cannot be given—thus, anisole not anisol, indole not indol.

MINERS' HOUSING.

THE National Housing and Town Planning Council issues a weekly record for the benefit of the Housing Committees of local authorities. The current issue, describing the garden suburb now being developed by the Bristol City Council at Sea Mills, and the scheme of the London County Council for a new town at Beaconsfield in Essex, makes timely allusion to the housing of miners. With the recrudescence of difficulties in the mining industry, it says, deep interest will be taken in the view expressed by many responsible and unbiased public men to the effect that a substantial part of the unrest to be found in mining districts—and more especially in the coal valleys of South Wales—is due to the absence of proper conditions of social life and of suitable housing conditions. "At its best, the mining village or town is not a thing of beauty. At its worst, the colliery slum, with its wellnigh primitive sanitary conditions and rows of back-to-back houses, can 'give points' to many of the worst slums of great industrial centres." It is alleged that the number of employers willing or able to take remedial action is small. One or two examples are then quoted to show that here and there the right kind of action is being taken; these, however, are said to be exceptional cases. "It is recognized by employers and colliery workmen alike that the task of providing homes for miners under happier conditions can only be adequately fulfilled by local authorities acting in co-operation with the State." Even now, however, nearly 100,000 houses are included in the building programmes of the local authorities for the various mining areas of England, Wales, and Scotland. It is said that the idea is rapidly growing amongst employers and workmen that it is not good

for those engaged in the mining industry to be segregated in villages and towns given over entirely to the housing of workmen engaged in coal mining. The Committee of the South Wales Regional Survey is understood to favour the development of fifteen new towns in the colliery valleys of South Wales, under such conditions that the miners may partake of the amenities of civilized life and live in closer touch with other members of the community. There is a great deal of truth and a certain amount of exaggeration in all this. In any large area where the greater part of the coal raised is exported to foreign countries, or even sent to other parts of our own country—and this is the case in large areas of the South Wales coal fields—it would be difficult to form communities containing any large proportion of persons engaged in other industries than the raising of coal. Nor are we at all sure that the task of providing homes for miners under happier conditions can only be adequately fulfilled through State help, or that the majority of employers are indifferent. It is perhaps not generally known that large anthracite areas are being taken up in South Wales. A cursory observation of the new towns erected or planned shows that they are free from the gross defects of the aggregates of houses that choke the valleys of the Rhondda district. The risk of such utterances as those of the Housing and Town Planning Council is that they may encourage both mine owners and miners to believe that it is hopeless to make a mining town or village a reasonably agreeable place to live in unless other industries than the raising of coal are there carried on.

TREATMENT OF TUBERCULOSIS.

IN accordance with that section of the National Health Insurance Act, 1920, which provides that sanatorium benefit shall cease to be included among the benefits of the National Health Insurance Act, 1911, after April 30th next, county and county borough councils have now received a circular letter from the Ministry of Health. It is pointed out that it will rest with these councils to provide institutional treatment for insured persons as well as for other members of the community, as Insurance Committees will after that date no longer have the duty of providing such treatment for insured persons suffering from tuberculosis. In practically every county and county borough a scheme for the institutional treatment of tuberculosis, comprising both dispensaries and residential institutions, is already in preparation or in course of development, and is available for the treatment of the whole population of the area. In the large majority of the areas agreements are also in operation by which the councils provide institutional treatment for insured persons suffering from tuberculosis in consideration of payments by the Insurance Committees. These agreements will come to an end when sanatorium benefit is discontinued, but in those areas in which the council has already undertaken by agreement with the Insurance Committee to provide institutional treatment for insured persons, no difficulty should arise in continuing provision by the council of the institutional treatment needed by such persons. In the remaining areas it will be necessary for the council to supplement the provision already made, either by taking over the arrangements made by the Insurance Committee for the provision of residential treatment, or by making other arrangements for that purpose under which an equivalent amount of residential treatment will be provided; there must of course be no interruption of the course of treatment provided by an Insurance Committee for any insured person. A separate memorandum has been issued dealing with the special arrangements which should be made by a council for the treatment of ex-service men suffering from tuberculosis. Provision is made for repayment to the council of the cost of residential treatment provided for ex-service men; the special services tuberculosis officers should render in relation to pension

administration are set out, and a new method of payment by the Ministry is formulated. By the National Insurance Act, sanatorium benefit of seamen and other persons employed in the mercantile marine suffering from tuberculosis was administered by the Seamen's National Insurance Society instead of by an Insurance Committee. A sum equivalent to the annual amount at present available for providing institutional treatment by that society will be distributed among the councils of those areas in which the society's members are located, and it is necessary that, as the majority of seamen have no permanent place of residence, cases of tuberculosis should be dealt with by the councils as a matter of urgency. As insured persons will no longer be in a position to apply to their Insurance Committees for sanatorium benefit after April 30th, cases of such persons and of other members of the community suffering from tuberculosis should be brought to the notice of the local tuberculosis officer at the earliest possible date, and it is suggested that councils should again circularize the medical practitioners practising in their areas drawing attention to the importance of utilizing freely the services of the local tuberculosis officers.

SIR WILLIAM THORBURN.

Though Sir William Thorburn retired at the end of last year from the active surgical staff of the Manchester Royal Infirmary rather before the date required by the age limit rule, and in consequence ceased to be professor of surgery in the Manchester University, he has not given up teaching nor the practice of his profession. Since his election to be consulting surgeon he has been appointed to give lectures on the surgery of the nervous system at the Manchester Royal Infirmary; the first series will be given there during June next. Sir William Thorburn is at present in Rome, whither he went as president of the British Chirurgical Club, which exists to enable its members to study surgical methods of other schools and other countries. Sir William Thorburn's reputation as a surgeon is particularly high in the department concerned with the treatment of diseases and injuries of the nerves, and the profession, especially in the north of England, will be glad to know that it is not to be deprived of his experience and skill.

Dr. THOMAS LEWIS, F.R.S., will deliver the Oliver-Sharpey lectures before the Royal College of Physicians of London, at 5 p.m., on Tuesday, April 12th, and Thursday, April 14th, at the College, Pall Mall East. The subject is: "Observations upon the nature of auricular flutter and fibrillation."

The Right Hon. Evelyn Cecil, M.P., has retired from the office of Secretary-General of the Order of St. John of Jerusalem, and has been succeeded by Lord Stanmore. Mr. Cecil had held this, the chief executive office of the Order of St. John, since 1915. He became a member of the Joint War Committee of the British Red Cross Society and the Order of St. John five years ago, and has been vice-chairman of the Joint War Council for the last two years.

On Friday, April 15th, at 5 o'clock, in the Museum of the Royal College of Surgeons of England, Professor Arthur Keith will demonstrate specimens illustrating the comparative anatomy of the caecum, appendix, and great bowel.

At a meeting of the Central Midwives Board for England and Wales held on March 23rd, with Sir Francis Champneys presiding, one midwife was struck off the roll, one severely censured, two put on probation for reports in three and six months, and one case was dismissed, the midwife being cautioned to obey the rules strictly. Various appointments were made to fill vacancies caused by the resignation of examiners, and lists of examiners, lecturers, and institutions, homes, and midwives, at which and under whom pupil midwives may be trained, were approved.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Ministerial Changes.

THE reconstruction of the Ministry, which has followed upon the retirement of Mr. Bonar Law and upon the occurrence of other vacancies, has brought numerous changes in the placing of members of the Government, and a small and valuable infusion of fresh blood. The list has been made familiar through the daily papers, and need not be referred to in detail here, except as regards the departure of Dr. Addison from the Ministry of Health and the selection of Sir Alfred Mond to fill that office. The fact that Dr. Addison remains a member of the Cabinet as a Minister without portfolio—that is to say, in a consultative and influential capacity—shows that he enjoys in a high degree the confidence of the Prime Minister; and inasmuch as under the Coalition arrangement the Cabinet appointments are—figuratively speaking—countersigned by Mr. Austen Chamberlain as leader of the Unionist Party, there is evidence that Dr. Addison is also held in appreciation by the Unionist chief.

It may be assumed that the selection of Sir Alfred Mond is due mainly to the desire of the Prime Minister to have at the Board of Health a commercial man with better business qualifications than Dr. Addison, in the nature of his career, could possess for dealing with the housing problem, which is causing so much anxiety at the present time. Sir Alfred Mond had much experience during the war, as First Commissioner of Works, in arranging for the accommodation of emergency war services, and even in the ordinary way the position he has now given up to become Minister of Health afforded him special knowledge in this connexion. His wide responsibilities in chemical manufactures before he entered the Government trained him, moreover, to think largely and to estimate closely on these subjects. His capacity for handling big figures was shown also during fiscal controversies in pre-war days.

Happily there is no reason to fear that because Mr. Lloyd George's choice has been determined principally by the housing situation Sir Alfred Mond will be lacking in concern to take up health questions, or will fall in capacity or vigour in handling them. At the works of Messrs. Brunner, Mond at Droitwich and elsewhere keen anxiety has been manifested to recognize the importance of hygiene. Indeed, the nature of some of the undertakings has called for much care, and the Directorate are proud of the scientific administration which has given such good results in the physical condition of the employees. With this record at the back of his mind, Sir Alfred Mond will, it is anticipated, desire to continue and promote a forward movement at the Ministry of Health in all things affecting the well-being of the people, and be sympathetic to the medical profession.

The new Ministers are generally considered to have been well chosen. There is satisfaction that at last the Air Ministry obtains a directly responsible head; to this work Captain Guest will bring energy and enterprise. Commander Hilton Young, who succeeds Mr. Baldwin as Secretary to the Treasury, has amongst private members shown himself far and away the ablest debater on financial subjects that recent years have produced. He doubtless gained some strength from experience earlier as the city editor of a London journal. Sir Robert Sanders, who was the right hand of Lord Edmund Talbot in the Whip's office, should prove highly capable as Under Secretary for War; he is none the less efficient because he has shunned the limelight of politics. Major the Hon. E. F. L. Woods, the eldest son of Lord Halifax, has distinguished himself as a thoughtful and careful speaker, and his broad interests will find opportunity for service in the Under-Secretaryship for the Colonies. Altogether the juniors look likely to justify their selection.

The Bradford Municipal Hospital.—Mr. George Thorne asked the Minister of Health, on April 5th, whether he could state the present position in regard to the acquisition of a Poor Law infirmary by the Bradford Corporation, to which he had at one time given his sanction, which, as Mr. Thorne understood, was afterwards withdrawn. Sir Alfred Mond replied that provisional sanction was given to the scheme in June last, and this had never been withdrawn. But before giving a final decision the Minister of Health had urged on the Council the importance of full consultation with the medical profession in Bradford. As the result of this, a local advisory medical committee was appointed, and this committee had put forward certain suggestions which were being considered by the City Council, from whom a communication was expected to be received soon.

England and Wales.

SUPPLY OF MILK TO NURSING MOTHERS.

A CIRCULAR has been addressed to local authorities by direction of the Minister of Health stating that, in the supply of milk for expectant and nursing mothers and children under five years of age, many local authorities have incurred expenditure very greatly exceeding what is either necessary or desirable. This conclusion has been reached after a careful review of the cost of the schemes adopted throughout the country by local authorities with comparable needs. The Minister has accordingly reconsidered the arrangements to be observed as a condition of his sanction to schemes, and it appears to him that the necessities of those whom the service was designed to benefit could be met by a much lower rate of expenditure than that now being incurred. The Milk (Mothers and Children) Order, 1919, made by the Food Controller and the local authorities, and the Milk (Mothers and Children) Order, 1919, made by the Minister of Health, have therefore been revoked, and local authorities must in future obtain the sanction of the Minister of Health under the Maternity and Child Welfare Act, 1918, to schemes for the supply of milk to expectant and nursing mothers and children under five years. Milk may be supplied at less than cost price in necessitous cases only to (a) nursing mothers; (b) expectant mothers in the last three months of pregnancy; (c) children up to three years of age, and exceptionally to children between three and five years of age. The quantity of milk supplied at less than cost price must not ordinarily exceed one pint a day for each person, but in exceptional cases one and a half pints may be supplied for infants from three to eighteen months. Milk should be given only where the medical officer of health is satisfied that it is essential on grounds of health, and for exceptional cases a medical certificate will be required. A special committee should be appointed locally to lay down the procedure for dealing with applications for milk and to review all authorizations for supply. Reasonable steps must be taken by local authorities to verify the particulars of income given by applicants, and to prevent overlapping with other bodies concerned. Where dried milk or preparations of milk are used the quantity should be such as would, when reconstructed, approximate to the usual supply of fresh milk.

JOINT MEDICAL MEETING AT SHEFFIELD.

A joint meeting of the Sheffield Medico-Chirurgical Society and the British Medical Association was held on March 24th in the Firth Hall of Sheffield University, and the chair was taken by Dr. F. J. Sadler. Dr. Rupert Hallam gave a short account of his journey round the world as the medical member of a Commission which was dispatched to the Far East by the National Council for Combating Venereal Diseases with the approval of the Colonial Office. The Commission first visited New York, arriving there early in November, 1920, where Dr. Hallam had the opportunity of seeing several of the well known skin and venereal clinics. The majority of patients there pay for their treatment, but necessitous patients are able to obtain free treatment. Compulsory notification and treatment of venereal disease has been in force for more than a year, and the consensus of opinion is that this has not acted as a deterrent to patients to seek treatment. He next visited the New York State Laboratory at Albany, which is a large and well-equipped building. The Commission journeyed across Canada, making brief stays at Toronto, Winnipeg, Regina and Victoria, where meetings were held under the auspices of the Canadian Council for Combating Venereal Disease. In Japan useful information was obtained from the officials of the Government Health Department, and visits were paid in two hospitals in Tokio. At the invitation of the Shanghai Municipal Council the Commission conducted a campaign of public enlightenment in that city, and Dr. Hallam gave a series of lectures and demonstrations to the medical practitioners there in the diagnosis and treatment of venereal disease. The incidence of both syphilis and gonorrhoea among the Chinese in the seaport towns is very high, and before the visit of the Commission there was no treatment by modern methods available for them. The Commission conducted a

similar campaign at Hong Kong, Singapore and Colombo, and in each of these ports recommended that the free diagnosis and treatment of venereal disease should be provided.

Ireland.

THE LATE DR. J. A. HANRAHAN.

WE have received the following appeal, signed by Dr. James W. O'Connor, Professor of Physiology, University College, Dublin, and Mr. W. Doolin, M.B., F.R.C.S.I., Honorary Secretary of the Leinster Division of the British Medical Association, who write from 50, Fitzwilliam Square, Dublin:

"We ask the liberty of appealing through your columns on behalf of the widow and children of the late Jas. A. Hanrahan, M.B., a recent Dublin graduate. Dr. Hanrahan graduated in the Royal University in 1909; shortly after he went abroad to take up practice in Australia, from which country he returned home last year, to die of inoperable rectal cancer at the early age of 34. Unhappily he was too short a while in practice to make any effective provision for his family. His unhappy widow, herself seriously handicapped by reason of deafness, is now left with four young children to maintain. In these circumstances we would now appeal to your members and readers for any measure of assistance, however small, that they can afford. Subscriptions, which will be duly acknowledged, may be sent to either of us."

Scotland.

VITAL STATISTICS FOR 1920.

THE outstanding statistical facts derived from an examination of the annual report for 1920 of the Registrar-General for Scotland are high birth and marriage rates and a low death rate. The marriage rate, 9.6 per 1,000, is the highest Scottish marriage rate yet recorded, while the death rate, 14.0, is the lowest. The birth rate was 28.1, and is higher than that of all years since 1906. Deaths from tuberculous disease show a satisfactory decline. Deaths from whooping-cough were fewer than in any previous year, and those from measles also declined. Births registered in Scotland during the year numbered 136,535; this was 30,267 more than in the previous year, 31,258 more than the mean of the numbers of the preceding five years, and 22,599 more than the mean of those of the preceding ten years. It is the largest number of births registered in Scotland in any one year, the previous largest number being in 1903. The increase was due to large numbers in the first two quarters of the year only, there being no marked excess over pre-war averages in those of the latter two quarters. Deaths registered numbered 68,179, or 6,970 less than in the previous year, 6,876 less than the mean of those of the five preceding years, and 5,643 less than the mean of the ten preceding years. It is less than the number registered in any year subsequent to 1862. The natural increase of the population of Scotland during the year (the excess of births over deaths) was 68,356, a number greater than in any previous year since the institution of national registration—that is, since 1855. The birth rate was 28.1 per 1,000; it was 6.4 higher than that of the previous year, and higher than the rate of all years subsequent to 1906. The annual death rate was 14 per 1,000; it was 1.4 less than that of the previous year, and 1.5 less than the mean of those of the preceding ten years. It is the lowest annual Scottish death rate yet recorded. The deaths of children of less than 1 year old numbered 12,565, equal to an infant mortality of 92 per 1,000 registered births. This rate is 10 less than in the previous year, 15 less than the mean of the preceding five years, and is the lowest annual Scottish infantile mortality rate yet recorded. The death rate due to the principal epidemic diseases was 0.78 per 1,000. This is 0.14 less than in the previous year. The death rate from all forms of tuberculous disease was 124 per 100,000, and from phthisis 85. Both of these rates were the lowest yet recorded. Deaths from small-pox registered during the year numbered 152, which is the largest number in any year since 1904. Deaths from measles were fewer than

in any year since 1894, while from whooping-cough they are fewer than in any previous year. Deaths from cancer were more numerous than in any previous year; they outnumbered those attributed to phthisis by 1,563, or fully 37 per cent.

END OF GLASGOW SMALL-POX EPIDEMIC.

The last case of small-pox in Glasgow has now been discharged from hospital, and the city for the first time in twelve months is free from this disease. The epidemic started in March of last year, and altogether the Public Health Department dealt with 576 Glasgow cases and 26 cases from Rutherglen burgh and the County of Lanark. Of the total cases 119 proved fatal, the deaths without exception occurring among patients who had never been vaccinated or who had not been vaccinated for a considerable number of years. The disease was at its height towards the end of May, when there were 157 cases in hospital at the same time. About a quarter of a million persons were vaccinated by the officials of the Health Department, assisted by a large number of medical students, and the education authority carried out a systematic campaign of vaccination in the schools.

Correspondence.

ACIDOSIS AND ALKALOSIS.

SIR,—In his letter in the BRITISH MEDICAL JOURNAL of April 2nd Dr. Poulton suggests that what is known as diminished or increased "alkaline reserve" of the blood should be called "acidosis" or "alkalosis," regardless of whether the actual reaction of the blood is altered in the acid or alkaline direction. I feel sure that nothing but confusion could result if such a nomenclature were adopted; and mistakes have actually arisen in the past through taking variations in the "alkaline reserve" as in themselves an index of whether the blood is altered towards the acid or alkaline side. I need only instance the case of treatment of lung-irritant gas poisoning by administration of alkalis, in disregard of the urgent danger from anoxaemia.

It is now clearly established that, as was illustrated in my lecture, the "alkaline reserve" may be, and often is, diminished in cases where the blood is abnormally alkaline; and conversely that the "alkaline reserve" may be increased where the blood is deficient in alkalinity. The expression "alkaline reserve" is an unfortunate one, in so far as it suggests the existence of a reserve of alkali beyond what is required to maintain a normal reaction. In actual fact the whole of the normal "alkaline reserve" of the blood is required to balance the carbonic acid normally present. When less or more carbonic acid than usual is present the "alkaline reserve" is gradually diminished or increased to such an extent as nearly to restore, if possible, the normal reaction. Conversely, if the "alkaline reserve" is increased or diminished the carbonic acid in the blood is, by diminution or increase of the breathing, so increased or diminished as, if possible, nearly to restore the reaction.

An instance of diminution in the carbonic acid of the blood, with consequent diminution in its "alkaline reserve," is furnished wherever increased breathing is caused by anoxaemia. An instance of diminution in "alkaline reserve," with consequent increased breathing and diminution in the carbonic acid in the blood, is afforded by any case in which acids accumulate abnormally in the blood. This occurs to an extreme extent in diabetic coma, of which the phenomena seem to me to point very clearly to a condition of extreme acidosis, along with secondary damage where the condition has lasted for some time, just as there is secondary damage when anoxaemia has lasted for some time.

For "alkaline reserve," one might substitute some such expression as " CO_2 -combining capacity"; but probably the more picturesque expression "alkaline reserve" will survive, as it is now so extensively used. To define acidosis or alkalosis as diminution or increase in "alkaline reserve" is, however, so definitely misleading that I feel sure that such a definition ought to be avoided. Acidosis and alkalosis are extremely small, but also extremely important, deviations from normal in the hydrogen ion concentration within the body. The available direct physical and chemical methods are still too rough to

enable us to follow these deviations closely; but we can do so by the far more delicate method of observing the accompanying changes in breathing and in the excretion of acid or alkali and ammonia by the kidneys.—I am, etc.,
Oxford, April 3rd.

J. S. HALDANE.

CARDIAC PERISTALSIS AND MITRAL STENOSIS.

SIR,—In his thoughtful paper on "Cardiac peristalsis and mitral stenosis" Dr. Samways brings out an important fact in connexion with the mechanism of the heart beat—namely, that during the initial phase of closure the semilunar valves are supported by contracted ventricular muscle, and the auriculo-ventricular valves by contracted auricular muscle.

Some years ago I drew attention to the incompetence of the aortic semilunar valves to support the aortic blood pressure, emphasizing this incompetence by asking what would happen if a portion of the aortic wall were replaced by semilunar membrane. Obviously rupture would speedily ensue. I suggested that during the early phase of semilunar closure the ventricular wall adjacent to the valves remains contracted, thus affording the closed valves the needful support until such time as the rising intra-ventricular pressure is adequate for the purpose. This explanation has since been established as a fact. Presumably the same line of argument applies to the auriculo-ventricular valves, though the conditions in their case are somewhat different.

Curious that so glaring a fact as the incompetence of semilunar tissue to sustain for a century or more rhythmic pulsations of 100 Hg pressure should have escaped the physiologists. Modern textbooks on physiology still overlook it. Other essential truths in connexion with the circulation are similarly neglected. Indeed, I make bold to assert (what may perhaps shock, but I trust will not offend, the professed physiologist) that it is not possible to get a proper insight into the physiology of the circulation from any modern students' textbook of physiology—at least not from any I have consulted.

Here, for example, are a few among several fundamental points wholly ignored in these works, although an understanding of them is essential for a proper understanding of the circulation: the meaning of the great excess of the aortic over the pulmonary blood pressure (how comes it, for example, that the aortic pressure of the mouse is greater than the pulmonary pressure of the horse?); the object of the muscle tissue in the aorta and other large blood vessels and in the veins; its abundance in the veins of the lower limbs; its scantiness in the veins of the neck and its entire absence in the intracranial, interosseous, and intraocular veins.—I am, etc.,

London, April 3rd.

HARRY CAMPBELL.

THE FUTURE OF RESEARCH IN TROPICAL MEDICINE.

SIR,—I much regret if in my recent address I have done any injustice to the Committee for the Prevention of Tropical Diseases through inadvertently using the word "island" in the singular instead of the plural, although it in no way affects the principle for which I was contending—namely, that the time has come for a further advance in the way of establishing more permanent research laboratories in British tropical possessions rather than in sending out further expensive temporary expeditions.

I am surprised at Dr. Jensen's statement that I should have been welcomed at his committee's meetings, considering I received no notice of them, and in view of the fact that I have waited in vain for six months for any reply to my letter to him setting forth the views I expressed in my recent address and offering to join the committee if at any time they adopted the policy I advocated. As a matter of fact, one of the two copies of the circular he sent me was not marked "proof" or in any way as confidential, while judging from the long list of members of the committee, scattered all over the world to whom it had presumably been sent, it never occurred to me that the committee did not think it wise to allow their policy to see the light of day. The decision as to which is now the better policy may safely be left to the real arbiters—the holders of the purse-strings.—I am, etc.,

London, W., April 4th.

LEONARD ROGER.

THE COLLECTIVE OPINION OF THE
PROFESSION.

SIR,—I should like to support the letter of Dr. Fothergill in this matter (BRITISH MEDICAL JOURNAL, March 5th, p. 362), and hope that the Council will accept and act upon the suggestion of a questionnaire. I especially want to see the formation of a committee of medical men who should represent the views of the medical profession and the medical profession alone, and one which should not profess to promote the interests of the community rather than those of the medical practitioners engaged in active practice. If the large number of medical men at present outside the British Medical Association could only be convinced that these two objects could be attained, I feel sure that the Association would soon be invincible and absolutely beyond the caprice of bureaucracy.—I am, etc.,
S. NOY SCOTT.

Plymstock, S. Devon, March 23th.

EVOLUTION IN RELATION TO DISEASE.

SIR,—Your first leader in the issue of the BRITISH MEDICAL JOURNAL of March 19th, on the new epidemiology, induces me to write the following remarks. In a contribution to the Epidemiological Society of London on March 16th, 1906, on the above subject, I opened with the statement that

"there are times when it is essential for real progressive knowledge that we should pause and contemplate the discoveries already made and the knowledge already achieved. The pure scientist is by nature cautious—so cautious, indeed, that if he alone were to deal with the problems of science progress would naturally be slow. Many a biologist has looked at but not recognized under his microscope some organism of high importance which later has been readily perceived by a more philosophical observer who has allowed analogy and deduction to influence his researches."

When I read a paper on "The evolution of disease and disease germs" at a Public Health Congress at Eastbourne in July, 1901, a well-known medical officer of health—who subsequently achieved the highest distinction—denounced my deductions as "dangerous." (His latest writings reveal that he is a convert.) Another well known medical officer of health stigmatized my suggestions as "absurd." At that time I advanced my arguments as the results of my own bacteriological observations and cogitations thereon when demonstrator of bacteriology at King's College, University of London, and was unaware of any previous philosophical reasoning on the subject. But I shortly afterwards learned that I was in good company—both as regards the thesis I advanced and the sarcasm and antagonism with which it was received—in the person of Sir William Collins, who had enunciated similar views in a letter to the *Lancet* of May 14th, 1881, which had been ridiculed even by the medical press. My contribution to the Epidemiological Society in 1906 met with a kinder reception, and gave rise to a valuable discussion opened by the late Dr. Payne, whose reputation as a scientific pathologist was well founded. Those interested in evolutionary pathology will find in his remarks a most entertaining and picturesque application of the Darwinian system to disease processes.¹ Only so recently as last year Sir William Collins contributed a historical retrospect on "Specificity and evolution in disease," dating back to his original letter of May 14th, 1881.²

In the course of the discussion on my paper in 1906 Dr. W. H. Hamer, remarking that, while my views were somewhat unorthodox, I had submitted my thesis to a tribunal likely to give it careful and sympathetic consideration, did grant service in reviewing previous evidence of interest on the part of members of the Epidemiological Society on the relationship between scarlet fever and diphtheria, such interest dating back to remarks by Dr. Burdon-Sanderson in 1858-59, when a Diphtheria Subcommittee was appointed. A point specially considered by this committee was the extent to which epidemics of diphtheria had been coincident in place and time with epidemics of scarlet fever. Dr. Ransome, in 1875, attached importance to two points as showing that diphtheria and scarlet fever were not identical—one of his objections was that, whereas scarlet fever was milk-borne, diphtheria was not; the other was that diphtheria was commonly spread by

sewer air, not so scarlet fever. Both objections are now anachronisms.

In my paper I devoted especial attention to the bacteriological side of the problem, commenting on the frequent association of streptococci, Hoffmann's bacilli, and Klebs-Loeffler bacilli in the swabbings of throats from both scarlet fever and diphtheria patients, and I still hold the view, as suggested in the BRITISH MEDICAL JOURNAL, 1902, vol. i, p. 56, that these organisms, though by many to be well-defined "species," are interchangeable varieties in the life-history of a common saprophytic organism which has passed through evolutionary phases on different lines, giving rise under certain conditions to an organism which, in susceptible persons, brings about reactions recognizable in the form of a clinical entity known as scarlet fever; while under other evolutionary conditions the organism becomes what is known as Klebs-Loeffler bacillus, with reactions in susceptible persons inducing a clinical entity recognizable as diphtheria. But betwixt definite scarlet fever and definite diphtheria are many less definite clinical conditions; many of these are associated with what is known as Hoffmann's bacillus. In the later stages of both scarlet fever and of diphtheria Hoffmann's bacillus is frequently found as the principal organism in throat swabs. I have observed elements in a chain of streptococci assuming bacillary forms. Once again I repeat what I said in 1902: "True scientific instinct should bear in mind the perturbing influences of evolutionary factors in disease." I cannot here more than mention the probabilities of a common ancestral stock for puerperal fever, erysipelas, rheumatic fever, scarlet fever, and diphtheria; or of a similar common ancestral saprophytic original organism for the various typho-coli races of bacteria and their resulting fevers; or of another for measles, small-pox, alastrim, varicella, and vaccinia.

In addition to the bacteriological side there are sides of the problem both important and interesting, such as the epidemiological relationship which Dr. Longstaffe pointed out between seasons of drought and scarlet fever, diphtheria, etc. It is now known that both diseases may be spread by milk and school attendance, and in both diseases "return" cases are not infrequent.

In my reply to the discussion on my paper in 1906 I laid stress on the importance of symbiotic relationship in individual throats; in some favourable, in others inimical to the evolution of function and even of morphology. Such can be studied only by sustained observation of cultures made from daily swabs of the particular throat in question. This was my special method of observation, having a fever hospital and bacteriological laboratory at command. The only likely method of demonstrating such observations to others would be by calling in the aid of photomicrography.

Now that evolutionary pathology appears to be coming into its kingdom it is appropriate once again to draw attention to the monumental and hitherto unaccepted scientific work of the late Dr. Charlton Bastian dealing with archeobiosis and heterogenesis. It is highly probable that all bacteria are merely stages in the extremely complicated cycle of low forms of life.

How history repeats itself, even in the advancement of human knowledge, may be realized by a careful perusal of Darwin's historical sketch of the progress of opinion on the origin of species previously to the publication of the first edition of his celebrated work. Thus we may go back a hundred years to find the real pioneers of evolutionary pathology, and to learn that even then thoughtful men had been forced to the conclusion that "species are only a higher and more permanent (or stable) class of varieties." How seldom can lowly bacteria achieve and maintain such permanency! How extremely probable that therefore there should be such variation in disease—sometimes malignant, at others so mild as to create doubt whether the epidemic illness prevalent is to be called scarlet fever, or influenza, or Dunn's disease, or "fourth disease," or "new disease."

The publication of my book on *Evolution and Disease* brought me copies of interesting and instructive papers by distinguished American authors. Among others, one on variation in type of infectious disease as shown by the history of small-pox in the United States, 1895-1912, by Charles V. Chapin.³ The evidence pointed to the existence

¹ Transactions of the Epidemiological Society of London, vol. xiv, 1905-1906, p. 231.

² *Lancet*, 1920, i, p. 1059.

³ *Journal of Infectious Diseases*, September, 1913.

in North America during this period of two distinct strains of small-pox, both tending to breed true, though it was possible that a few outbreaks of the severe type may have developed from the mild type which received a great variety of names—Cuban itch, army itch, bean itch, rhobio itch, cedar itch, African itch, Spanish measles, Japanese measles, bean-pox, water-pox, etc. A similar mild type of small-pox in England occurred in 1919. Of a more speculative nature is the highly interesting presidential address to the Connecticut State Medical Society, delivered by Dr. Stephen J. Maher in May, 1915.—I am, etc.,

Norwich, March 31st.

J. T. C. NASH.

BOVINE TUBERCULOSIS.

SIR,—At a recent discussion of the Royal Society of Medicine on the "Eradication of tuberculosis in man and animals," Professor Lylo Cummins is reported to have said he could not free his mind from feeling that it (partial vaccination by a bovine strain and prolongation of the disease in the class of case in which milk might be concerned, the middle-aged type) did exist, although he would regard the advocacy of such vaccination as entirely unjustifiable.

He would therefore, I imagine, believe that for this end to be attained bovine tuberculosis must have been on the increase during the past fifty years, the period in which human tuberculosis has shown such a marked decline. The opponents of the immunity theory would probably consider that bovine tuberculosis had also declined during this period, a supposition which seems just as probable as the other.

Are there any statistics in existence relating to the incidence of bovine tuberculosis during the past fifty years? I imagine not. If there were, they would be interesting with reference to the question of immunity. Infancy and childhood are the periods of life in which the largest quantities of milk are consumed, but until the present century these were the age periods in which, to quote the report of the Registrar-General, "the fall of mortality amongst young children has previously lagged somewhat behind those at most, and for females at all ages."

Childhood and the earlier adult years of life are also those in which the infectious illnesses mostly occur, and during these illnesses increased quantities of milk are taken. In these age periods also the non-pulmonary and bovine forms of tubercle are most prevalent.

The dose of bacilli in milk at any time must be x , but this being understood the following questions may be put. If this partial immunity exists, when does it begin to develop, when is it most potent, and when does it begin to decline? Surely it ought to be most potent in childhood and gradually become less dominant, yet Professor Lylo Cummins suggests that it has most influence in the middle-age type of disease, and not with the young adult type.

Whatever views may be held as to the benefit or danger of the consumption of tuberculous milk by children, I have never yet met anyone who suggested that the drinking of such milk by adults was an advantage to the consumer. If it were so, in the opinion of those who believe in partial immunity, it would be an argument against attempting to diminish the incidence of bovine tuberculosis.—I am, etc.,

Guernsey, March 29th.

H. D. BISHOP.

ADRENALINE IN RESUSCITATION.

SIR,—The valuable letter of Mr. Lockhart-Mummery on p. 100 of the JOURNAL on January 15th may appeal to more of us than he seems to think.

Surely he makes too much of his dilution of adrenaline to 1 in 50,000 before administration. Experimental physiologists have long recognized with regard to intravenous administration that dilution of drugs with the blood can be secured to any extent by slowness of injection. That Mr. Lockhart-Mummery found by his observations that 1 in 50,000 was the optimum dilution of adrenaline means no more than that it was the optimum at the rate at which he injected; no two operators would inject at the same rate and so secure the same dilution in the general circulation, however constant the contents of their syringes were.

The "person skilled in the use of adrenaline transfusion," the necessity for whose presence Mr. Lockhart-Mummery considers such a grave limitation of the scope of the procedure he advocates, need be no other than any one of us who is accustomed to using a 10 or 20 c.cm. syringe for intravenous medication.

It is this recognition that the blood is the best diluent that has changed the intravenous administration of quinine—for example, from being a procedure for those "skilled in transfusion" to being a matter of an intravenous injection easily within the competence of any tropical practitioner. Provided he takes the precaution of adding $m\ v$ of liquor adrenalinii to his solution, and of injecting slowly, he can avoid the one danger of intravenous injection of quinine—that of a drop in the blood pressure. The tetanus spore, the bogey of the intramuscular method, he may leave to be dealt with by the leucocytes; and his patients never remind him of his intravenous injections of quinine as they did of his intramuscular ones, followed so often by painful lumps dotted about just the parts of the body they wanted to lie on.

Intravenous medication is still in its infancy. Used with discretion it has a great future before it; and it is a distinct encouragement to its use, when indicated, that it is the one way of giving medicine which demands no accuracy of dilution in dispensing. The practitioner has only to judge, say, how many grains of quinine or atropin or how many minims of tincture of iodine he wishes to administer; he gives this in the nearest available syringe, without regard as to whether it be a 5 or a 10 c.cm. one, and in injecting he presses the piston very slowly, thus further diluting his drug with the most abundant, handy, cheap, and surely sterile saline solution he could use.

If Mr. Lockhart-Mummery, out of his experience, will tell us what is the dose of liq. adrenalinii hyd. (B.P.) to use in order to have the best chance of restarting a human heart that has stopped beating, we can do the rest.—I am, etc.,

J. L. MARJORIBANKS, M.D., D.P.H.,
Lieut.-Colonel I.M.S.

Aden, March 13th.

IRRITABLE BLADDER.

SIR,—Dr. Hamilton, in the JOURNAL of March 26th, p. 480, asks for information with regard to modern methods of treatment of irritable bladder. In true "irritable bladder," which is associated with frequent micturition, pain, normal urine, painless and elastic bladder walls, faradism, as advocated by my father, the late Dr. Samuel Sloan of Glasgow, gives most satisfactory results.

I have employed this treatment according to my father's directions. "An intrauterine bipolar electrode is introduced into the bladder with the usual antiseptic precautions. The current is taken from the secondary coil, the sedative form of current being thus employed." A dose of 2 to 3 milliamperes for fifteen minutes, given on alternate days for ten or twelve treatments, will suffice for cases of irritable bladder, but a second course of treatment may be necessary in those cases associated with injury to the bladder from pressure during parturition, with paralysis of the sphincter.—I am, etc.,

London, W., April 4th. ELIZABETH SLOAN CHESLER, M.D.

CHRONIC RETENTION OF URINE ARISING FROM PROSTATIC DISORDER.

SIR,—In reply to Mr. Clayton-Jones (March 19th, p. 411), may I point out that my paper of March 12th dealt with the treatment of only one of the symptoms of prostatic disorder—namely, that of retention—and not of others which may arise from the same cause—for instance, nocturnal vesical irritation? In this case the affected glands within the prostate are so situated that they stimulate the area of reflex, thereby giving rise to a more frequent desire to micturate, though they are not as yet large enough to produce increased resistance in the prostatic urethra.

Nocturnal vesical irritation is often the forerunner of retention, though it is by no means a sure sign of it—oncoming, for most men after middle life are more or less thus troubled, but, if tested, have no residual urine. Further, the symptom may, and often does, continue after retention has occurred. The desire to micturate is more

marked at night owing, I believe, to the fact that during the day, while volition is present, the slight irritation is either disregarded or inhibited, but when volition is withdrawn during sleep, or as sleep approaches, the excitant is exaggerated and is then sufficient to make the act imperative. Again, if the diseased glands do not interfere with the area of reflex a condition is produced which has been aptly described by Thomson Walker as "the silent prostate." The patient has few complaints and hardly any symptoms, but on investigation prostatic resistance is found to be increased, and there are many ounces of residual urine.

Nocturnal vesical irritation, although commonly associated with retention, does not necessarily imply that it exists; nor does the presence of this irritation negative the contention that "prostatic resistance is generally augmented by enlargement."

A patient complaining of nocturnal frequency and other defects, such as dribbling stream, urgency, and hesitancy, should be subjected to a systematic examination to ascertain the cause of the trouble. The only way of determining the presence of residual urine is by introducing a catheter immediately after the patient has passed all he can by his own efforts. The treatment afterwards is based on the condition found. With adequate precautions the risk of infection is exceedingly small; neither do I agree that a "breakdown" must almost certainly follow instrumentation performed by the patient himself for the purpose of treatment. It will not occur if he is taught to use the instrument properly, and is instructed in the details of an efficient and easy method of sterilization.

Finally, inducing the desire to micturate while the catheter is *in situ* will not produce any back pressure on the kidneys, mainly because the ureteric openings are firmly closed during vesical contraction, unless the disease is advanced and serious structural changes have already taken place, when the treatment would be worse than useless; and secondly, because the presence of the instrument reduces the prostatic resistance sufficiently to enable the muscle to deal with a normal load in a natural way, and at the same time prevents any undue pressure being put on the bladder.—I am, etc.,

London, W., March 30th.

HERBERT T. HERRING.

PROSTATIC SYMPTOMS AND THEIR CAUSES.

SIR,—I have been reading with much interest the recent contributions that have appeared in the JOURNAL on the troubles and symptoms of the enlarged prostate, and my interest is largely personal, as I have been for several years a sufferer from these myself. One's attention is naturally specially drawn to one's self when suffering, and occasionally new light may be shed and benefit derived by acting on the knowledge gained by introspection—*γνώσις σεαυτοῦ*. I am therefore glad to submit a few particulars of my own case.

I am 63, wiry, active, and, apart from bladder trouble, enjoying good health. But for ten or more years I have had symptoms usually regarded as entirely due to prostatic enlargement—mild at first, afterwards more pronounced. My prostate is moderately enlarged and elastic to touch. The capacity of the bladder is still up to 10 oz. The symptoms of my trouble are or were: Frequency of micturition, sudden urgency going on to incontinence if opportunity of relieving myself was not available. The stream was usually small and hesitancy in starting it not unusual—that is, some retention. I felt I would have greater relief if I could pass more urine after the flow had ceased. I often had pain at the end of the penis and in the perineum, radiating to adjacent parts of the thighs. Further, I was troubled with a very unusual symptom—namely, priapism. This came on generally during sleep as the bladder filled up, but subsided at once when the bladder was emptied.

Careful consideration of these symptoms has enabled me to realize that the prostatic enlargement, although a contributing factor, was not their main cause. The trouble I found was largely due to avoidable cause or causes, and after these were recognized and corrected I have felt better in every way, although I fear that as they have been operating to my detriment for a number of years unrecognized, permanent harm has resulted. Still, I am very much improved; of that there is no doubt. The

reaction of my urine, now normal, had been generally alkaline for a number of years, and this, in conjunction with the symptoms, I regarded as due to residual retention from prostatic enlargement. But now I know this was not the cause of the alkalinity. To explain: I may say I have been troubled with constipation for many years, and, like many others, got into the habit of obtaining relief by taking salines two or three times a week—generally seidlitz powders—with the result that the urine was markedly affected thereby, and became almost constantly alkaline in reaction. These salines, of course, give up their citrates or tartrates and become carbonates and phosphates. I find "phosphaturia" always appears after taking these salines. When such aperients are taken only occasionally no harm is done, as the effect soon passes away, but when taken habitually two or three times a week, as I used to, a marked effect is produced. The sensitive lining of the urinary passages, which in normal conditions is in contact with slightly acid urine, has to submit to the presence of a fluid of unnatural reaction and of irritating character, resulting in a slow inflammatory process, with thickening of the mucous membrane and subjacent tissues, including the prostate, which hypertrophies. Hence the explanation of most of my symptoms—the pain, sudden call, small stream, etc. The lumen of the passage of the urethra is small owing to tumefied mucous membrane and subjacent changes. I may add I have often seen stricture of the urethra, especially near the meatus, in elderly people with prostatic symptoms. As to the priapism, this is not so easily explained. It only appears when cerebral control is cut off, and only then when the bladder is distended. Priapism is seen occasionally in the newly born child and may last for weeks, causing distress to mother as well as child, and afterwards cease to trouble. Where death of the infant has occurred from other causes and a post-mortem examination made the only pathological finding in the genito-urinary system has been a deposit of uric acid concretions on the apices of the pyramids of the kidney—the so-called infarcts. What the association of these is with priapism, if any, I will not attempt to say. As to the causation of the symptom in my case it may be reasonable to infer that some similar process has been at work; it may be that deposits of uric acid or of alkaline salts, or both of these, was the cause of the trouble, but this is mere surmise. I should say I have no symptoms of tabes or other spinal cord disease.

I have been anxious to give the history of my troubles to your readers after reading the articles you have recently published, as it is likely that many other sufferers from what is usually regarded as simple prostatic enlargement are unconsciously responsible for their production.—I am, etc.,

March 27th.

SENECTUS.

ANGIO-NEUROTIC OEDEMA.

SIR,—Dr. Davis (p. 480) thinks me unduly pessimistic with regard to prognosis, but the impression I wished to give was that the tendency always remains, and that therefore recurrences are the rule, but they are apt to assume an attenuated form, so that to this extent Dr. Davis may take heart. In my experience, in the large majority of cases, the first series of invasions are the most severe, and of the most serious variety; for instance, those few cases I have seen in which the larynx has been involved have invariably occurred in the period of first invasion, recurrences of the disorder having been distributed in the superficial loose cellular tissues. The same remark applies to affection of the tongue. The first attack was by far the worst, subsequent attacks involving small areas only. Extremely uncomfortable, not to say painful, symptoms accompany the disease in its internal manifestations. A surgeon once told me that twice he began to operate upon patients for acute appendicitis only to find that angio-neurotic oedema of the gut was entirely responsible for the symptoms. When the oesophagus is implicated the condition is one of the utmost discomfort, and is apt to create alarm. It is remarkable that sometimes a series of cases occurs in which the mouth and throat are almost exclusively involved, and another series in which the subcutaneous tissue is attacked. There appears to be no reason for this beyond the relative

susceptibility of the patient. In those liable to angio-neurotic oedema the presence of a fly, or even of a particle of dust, in the eye will at once bring on the trouble.

If Dr. Davis will read Dr. Francis Hare's article upon the "Paroxysmal neuroses," in the February number of the *Practitioner*, 1906, he will probably find much help in its application to this condition. Dr. Edgeworth of Bristol has also contributed an interesting paper upon the subject (*Quarterly Journal of Medicine*, January, 1909, vol. 2, No. 6), and in a memorandum to the *Lancet*, June 2nd, 1906, I have tried to point out how Dr. Hare's remarks apply to the disorder, and, in view of my subsequent experience, I am more than ever convinced that the failure of the decarbonizing functions is chiefly responsible. Many incomplete cases occur, and are apt to be overlooked, so that, possibly, the disease is not so rare as is generally supposed.

I believe it is a well-known fact that an access of pyrexia banishes epileptic fits for a time. I have observed precisely the same incident in the course of angio-neurotic oedema. This may point to a relation between the two, or simply to a common origin in variations in carbonaceous income and expenditure with differing results. If, however, both diseases were found to be more closely related than is apparent, we might have to modify our point of view in the treatment of the major disease.—I am, etc.,

Exeter, March 29th.

CLAUDE A. P. TRUMAN.

GLANDULAR FEVER.

SIR,—The account of glandular fever in your issue of March 26th, p. 452, is interesting. It seems to be a very definite disease with well-marked clinical features. I have lately had a case in my own family.

The patient, a boy aged 4½ years, was strong and healthy up to a little time before Christmas, 1920, when he began to look pale and appeared out of sorts, and complained of easily getting tired. About January 16th he looked flushed in the evening, but no temperature developed. The same thing occurred the next evening. On the next morning his temperature was 100.4°, and he had some headache and he remained in bed. Next day the temperature rose to 101.4°, when a swelling was noticed under the middle of the right sterno-mastoid muscle, and he complained of pain on moving his neck. A patchy erythematous rash developed, chiefly over the shins, and one or two patches on the arms, face and body. This lasted three or four days. The nose bled rather profusely once. The glands on the left side under the sterno-mastoid then swelled up, but not so markedly as on the right side. The temperature ranged between 101° and 103°, but came down fairly rapidly to normal about the tenth day. During the illness constipation was rather marked. The pulse seemed quick, out of all proportion to the temperature, going up to 150 at the height of the fever, and being very irregular in force and rhythm, and the child looked and seemed very ill. Examination of the throat showed redness of the fauces but no enlargement of the tonsils. Unfortunately a swab was not obtainable, as the child resented having his mouth opened. The swelling of the glands lasted about ten days.

After the temperature had come down to normal the child was kept in bed a further ten days and on a sofa for a further fortnight, until the heart had settled down. Examination of the heart did not show any signs of dilatation, so the rapid pulse was probably due to a toxæmia.

Treatment consisted of glycerin and belladonna to the glands and a febrifuge mixture at first, followed by quinine and small doses of digitalis and strychnine. During convalescence cod-liver oil and malt and Parrish's food were given.

The child now looks well, but care is still exercised that he does not do too much. His brother, aged 6½ years, was in and out of his room during the illness, but did not develop anything, so possibly the disease is not very infectious.

For some time before the illness I had attended several cases of adenitis in children, but they were of the ordinary type, with sore throats and infection of the glands of the anterior triangle.

The theory that the infection may be a type of influenza may have something in it, for shortly after his illness a very widespread outbreak of influenza, beginning amongst the elementary school children, developed here and is still going on, and a large number of cases of bronchopneumonia have occurred.—I am, etc.,

Chichester, March 28th.

WALTER DICK.

THE Swedish Government has allotted 5,000 crowns to the Swedish Medical Association to help in the printing of the three scientific journals published by the association.

Universities and Colleges.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on March 16th. The title of Professor of Surgery of the University was conferred upon Mr. G. E. Gask (St. Bartholomew's Hospital) and the status and designation of appointed teacher were conferred upon Dr. T. R. Elliott, Professor of Medicine in the University. Dr. John A. Ryle was recognized as a teacher of medicine at Guy's Hospital Medical School.

The Royal Dental Hospital and London School of Dental Surgery and the National Dental Hospital and College, forming a department of University College Hospital Medical School, were continued as schools of the University (in dentistry only) for a period of one year, from January, 1921.

Professor A. D. Waller, F.R.S., was reappointed Director, and Dr. T. D. Lister, C.B.E., Treasurer of the Physiological Laboratory until the end of the session 1920-21.

It was resolved that the revised syllabus in pharmacology of the second examination for medical degrees, Part II (Red Book, 1920-21, pp. 247-9, and Blue Book, September, 1920, pp. 229-31) be operative in and after the year 1923.

The following were appointed to act as additional examiners in obstetric medicine at the M.B., B.S. examination in May, 1921: Dr. J. S. Fairbairn (St. Thomas's Hospital), Dr. T. G. Stevens (St. Mary's Hospital), or, failing either of these, Dr. E. Holland (London Hospital) or Lady Barrett, C.B.E. (Royal Free Hospital).

Mr. H. J. Waring has been reappointed by the Faculty of Medicine a member of the Senate for 1921-25.

Applications for the Jodrell Chair of Zoology and Comparative Anatomy tenable at University College (salary £800 a year) and the Chair of Anatomy tenable at St. Bartholomew's Hospital (salary £900 a year) must be received by the Academic Registrar by April 25th and April 14th respectively. Applications for a University Studentship in Physiology (£50 for one year) must be received by the Principal Officer, from whom full particulars can be obtained, by May 31st.

Course in Mental Deficiency.

A course of lectures on mental deficiency, arranged by the University Extension Board in co-operation with the Central Association for the Care of the Mentally Defective, will begin at the University of London, South Kensington, on Monday, May 23rd, and terminate on June 4th. It meets the requirements of the syllabus for the diploma of the University in psychological medicine. The course will consist of eleven lectures, with clinical demonstrations, on mental deficiency by Dr. A. F. Tredgold and five by Dr. F. C. Shrubsole on administrative procedure in the ascertainment and treatment of the mentally defective, supplemented by lectures on the psychology of mentally defectives by Mr. Cyril Burt; on methods of training mentally defective children by Miss Lucy Fildes, on psychoneuroses in relation to mental deficiency by Dr. Eric Pringle, and on the relation between crime and mental defect by Dr. W. F. C. Sullivan, medical superintendent of the Criminal Lunatic Asylum. Further particulars can be obtained from Evelyn Fox, at the University of London, Imperial Institute Road, South Kensington, S.W.7.

GUY'S HOSPITAL.

Dental Research Fellowship.

A Dental Research Fellowship Fund has been instituted, consisting of a sum of money not exceeding £300 per annum, awarded wholly or in part. Applicants, whether graduates or undergraduates, must have studied in the Medical School or Dental School of Guy's Hospital, unless the advisory body decides that the circumstances are exceptional. Holders of grants from the fund may, at the discretion of the advisory body, be part-time research workers. All research work undertaken with the aid of the fund must be entirely carried out in Guy's Hospital or the schools attached thereto, unless the advisory body agrees that, from the nature of the work, some portion of the study might with advantage be pursued elsewhere. Applications for grants from the fund should be made to the Clinical Research Committee of Guy's Hospital, London Bridge, S.E.1.

UNIVERSITY OF DURHAM.

At the Convocation held on March 26th the following degrees were conferred:

M.D. (for Practitioners of Fifteen Years' Standing).—C. Corfield, B. J. C. Thompson.
M.S.—J. A. Berry, W. A. Hewitson, N. Hodgson.
M.B., B.S.—J. S. Clark, R. C. Davison, T. W. K. Dunscombe, North H. Hamilton, R. T. E. Naismith, J. D. Silverston, T. S. S. etc.
H. Toma, R. P. Wanless.
B.S.—Margaret B. Herbst.
B.H. AND D.P.H.—W. L. Glegg.

UNIVERSITY OF EDINBURGH.

Department of Physiology.

THERE is a vacancy for an assistant in this department. Applications, with full information as to qualifications and previous work, should be addressed to Professor Sir E. S. Gifford Schaffer, from whom particulars of salary, nature of work, etc., may be obtained.

UNIVERSITY OF ABERDEEN.

A GRADUATION ceremony was held on March 31st, when the following medical degrees were conferred:

M.D.—J. B. Milne.
M.B., Ch.B.—† J. Craig, † Eleanora M. P. Law, † D. R. MacDonald, † Mary M. Pyper, † I. R. Spack, C. D. Allan, J. J. H. Anderson, † N. C. Bodenstern, F. K. Chen, Lilian F. Gall, R. K. Grant, G. G. W. Hay, Margaret Lipp, M. H. Legg, A. Vachay, Elsie Mackie, Katharina F. E. Vander, M. W. Morat, Isabella M. H. Murray, Mitchell, J. I. Moor, Marion E. Morat, Isabella M. H. Murray, Janet C. Nicol, A. E. Reid, E. N. D. Repper, J. P. J. Rossouw, G. Saint, N. C. Simpson, Ethel V. G. Smith, A. L. G. Thomson, L. S. Thomson, I. R. Wood.
D.P.H.—D. W. Berry, A. M. Dugan, F. A. Innes, H. R. Neilson, W. W. Nicol, J. A. Sellar, Agnes L. Simple.
* Passed Final Medical Professional Examination with distinction.
† With second-class honours.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examinations indicated:

M.B., Ch.B. (*Medical Jurisprudence and Public Health*)—M. Brown, J. I. Cameron, J. A. Cameron, A. J. G. Capora, W. Houston, T. J. Jones, D. Lamont, A. Logan, G. H. Macartney, W. M. McCash, J. W. M. Conville, F. M. Elwee, C. F. H. M. Fadden, J. J. McGhee, T. J. McKail, E. J. MacPhail, W. B. M. Queen, R. S. V. Marshall, W. Muir, A. Snaddon, J. Snaddon, W. A. M. E. Stewart, H. V. Sweeney, D. M. Thompson, L. J. T. Thompson, A. F. White, A. Wilson, Marion C. Boyd, Mary D. A. Boyd, Jennina G. Brodie, Margaret G. Carrick, Katharina L. Cooper, Elizabeth Coup and Isabella C. Darling, Martha D. Devon, Jean V. Gledhill, Mary D. Gilmore, Annie W. Humble, Frances B. C. Livingston, Joan A. MacColl, Henrietta L. Paterson, Joanna T. Rae, Jessie G. Service, Jeanie M. Strathie, Eleanora M. Torrance, Adeline G. Vallance. *Old Regulations* Francisco Ribeiro.

* With distinction.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL M.B. PART I—*Materia Medica and Therapeutics, Jurisprudence and Hygiene, Pathology and Bacteriology*: L. Stazansky, * A. E. Drottske, * T. C. B. L. B. Crawford, D. S. Spence, J. V. Carroll, R. A. O'Neira, Minnie Alper, R. Seale, Charlotte A. Stuart, J. D. Watson, F. B. D'Arcy, Ruth Lemon, C. W. B. McCalder, T. Malone Barrett, P. H. S. Feuche, J. E. Deane, J. O'Connor, H. J. L. Murphy, M. Sayer, J. G. Russell, D. H. Saayman, Dorothy C. H. Dorman, Muriel V. Odum, Mary H. Harcourt, L. Phillips, I. E. Myers, J. C. Byrne. *Materia Medica and Therapeutics, Jurisprudence and Hygiene*, H. Hall, W. T. Hogan. *Jurisprudence and Hygiene, Pathology and Bacteriology*.

Edith F. Willock, F. Y. Pratt, R. H. Satchwell, Dorothy A. Daly, C. S. Wilson, E. S. Horgan, Ruth F. Flavell, D. V. Latham, R. S. Chapman, J. A. Acheson, P. M. J. Bobbett, R. W. Power, T. W. Panter, J. D. Leahy, J. C. Davis, A. D. Ward, P. J. Leahy, G. C. B. Robinson, *Surgery*, E. C. Smith, D. de Bruin, H. V. Moore, J. D. Leahy, H. C. Deane, W. H. Smith, Margaret A. Stevenson, Dorothy A. Daly, L. Herzenberg, R. S.

D.P.H. PART I—*Chemistry, Bacteriology, Physics, and Meteorology*, T. J. Kilbride, T. P. Chapman, T. D. Gordon, H. Muller. PART II—*Sanitary Engineering, Sanitary Inspection and Report, Hygiene, Epidemiology, Vital Statistics, and Public Health Law*, T. J. Kilbride, H. Muller, T. P. Chapman, T. D. Gordon, Anna M. K. O'Halloran.

* Passed with high marks.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At a meeting of the President and Fellows, held on April 1st, the following candidates for the Fellowship of the College, who had been nominated on January 7th, 1921, were duly elected Fellows: Thomas Nather Thomson, Harold Pringle, M. D.

At the same meeting the successful candidates at the recent final examinations under the Joint Scheme of the Royal Colleges of Physicians and Surgeons, Ireland, were admitted Licentiates in Medicine and Midwifery of the College as follows: Mary Boland, Lucrétia H. H. Byrne, T. Cooney, B. J. Corne, J. A. Cusack, Edith M. L. L. Dodd, A. C. Esmonde, P. Gaffney, S. A. Gales, J. W. E. Graham, S. J. Halpin, T. J. Kerr, J. J. McLeary, P. Moylan, J. J. O'Sullivan, J. Teban (with honours).

Dr. CHACON, an eminent Spanish toxicologist and professor of obstetrics at the University of Madrid, has recently died.

IN 1919-20 there were 14,088 medical students in the United States; this was an increase of 1,036 over the number in 1918. The number of students who became qualified in 1919-20 was 3,047.

Obituary.

RUTHERFOORD JOHN PYE SMITH, Ch.M., F.R.C.S.,
Emeritus Professor of Surgery, University of Sheffield.

THE death of Mr. Rutherford Pye-Smith, which we announced briefly last week, will be felt as a personal loss, not only by the large circle of his friends, but by numbers of people of all ranks of society in Sheffield and district who have benefited by his professional skill or personal acts of kindness and sympathy. He was a worthy representative of a notable Sheffield family. His grandfather, John Pye-Smith, D.D., F.R.S., the eminent divine and geologist, left his native town in 1801 to settle in London; his father, Ebenezer Pye-Smith, F.R.C.S., was an honoured member of the medical profession, and it was in London that Rutherford John Pye-Smith was born in 1848. He and his elder brother, Philip Henry Pye-Smith, were educated at Guy's Hospital. The latter was the well known physician of Guy's, and editor of the first (posthumous) edition of Hilton Fagge's *Textbook of Medicine*, and editor and author of the subsequent edition.

Rutherford Pye-Smith took the diploma of M.R.C.S. in 1871 and that of L.R.C.P. in 1872; he became F.R.C.S. in 1875, and started practice in Sheffield in 1876. He was elected surgeon to the Sheffield Royal Hospital in 1877, and he devoted himself to the interests of that institution heart and soul. Although hampered by buildings and equipment that were then out of date and inadequate, he introduced Listerian surgery, and gradually effected a great improvement in the efficiency of the hospital on its surgical side. Though utterly incapable of advertising himself, and of a retiring and rather shy temperament, such abilities as his could not long remain unrecognized. He gradually won his way and took rank as one of the leading surgeons of the district. As an operator he was safe rather than brilliant. His technique was exceedingly careful and thorough, and his operative results were very good. As a clinician the accuracy of his observation and soundness of judgment were rarely at fault. He always kept in touch with the developments of surgery. One of the secrets of the success of his surgical work was that he was always hopeful and resourceful, however grave the case might appear. The amount of work he accomplished was extraordinary. His whole days were an unremitting round of toil, and a large part of the nights was spent in correspondence and literary labours. Everything he undertook was accomplished with untiring attention to the minutest detail. His activities included not only professional matters but various forms of social service, philanthropic and Church work, and in these he was much helped by the devoted assistance of his wife. He was never a rapid worker, and it was only by constant effort and exacting toil that he was able to get through the day's work and to satisfy his passion for accuracy and thoroughness.

After his retirement from the Royal Hospital staff in 1903, at the age of 60, he retained a large surgical consulting practice. He had been President of the Yorkshire Branch of the British Medical Association, and his address in Surgery at the annual meeting of the Association in Sheffield in 1903 will be remembered by those who heard it as full of shrewd observation, mature wisdom, and humour. From the University of Sheffield he received the degree of Ch.M. in 1903; he was professor of surgery in that university, and represented it on the General Medical Council from 1911 to 1919.

In the strenuous days of the war his knowledge and skill were needed for the treatment of the sick and wounded. Though almost worn out by thirty-five years of incessant work and in poor health, he responded to the call and joined the staff of the Wharfedale War Hospital. The younger surgeons who were his colleagues at that hospital know well the value of the work he did there, as did his patients, by whom he was known as the saviour of limbs. But the strain proved too much for his years and a constitution never robust, and, though he continued to do valuable service until the end of the war, he was forced to yield to the remonstrances of his friends and to restrict the range of his activities.

When the strain of the war was over there was no hiding the fact that his health was very seriously under-

mined, though he would never consider himself an invalid. The restful life of his country home at Ampthill did something to restore his health; but the weakness remained, and he succumbed to heart failure following influenza after a brief illness of two days. His name must be added to the long list of veterans who sacrificed their lives by devotion to duty during the war.

His most striking characteristics, which endeared him to a large circle of friends, were a transparent sincerity in all he did and said, and a beautiful serenity of disposition. No one ever saw him ruffled or impatient. In all difficulties or controversies he was ready to act as mediator or to effect a compromise.

No notice of Rutherford Pye-Smith can be complete without reference to his religion. His piety was entirely without aggressiveness, but no one who came in contact with him could doubt its sincerity and the influence exerted by religion on his every act and thought. It was manifest in his consideration for others, his modesty, his kindness and in his large-minded and large-hearted clarity. His patients all loved him, and to few can it be given to inspire such entire confidence as he did. His memory will be gratefully cherished by numbers of people of all conditions.

ROBERT MURRAY LESLIE, M.A., M.D. EDIN.,
M.R.C.P. LOND.,

Physician to the Prince of Wales's Hospital, Tottenham, and the Royal Hospital for Diseases of the Chest.

The death, announced in our last issue, at the comparatively early age of 55, of Dr. R. Murray Leslie, will be keenly regretted by a wide circle of friends, medical and lay. It was unexpected, though for the past few months he had been in failing health.

Robert Murray Leslie came of an old Scottish Highland family, being the son of the late Alexander Leslie, J.P., of Suddie, Munloch, Ross-shire, and one of six brothers, four of whom became members of the medical profession. He received his schooling at George Watson's College, from which he passed to the University of Edinburgh, where he graduated M.A. in 1888, B.Sc. in 1889, and M.B. and C.M. in 1892—all with first-class honours. In science and in medicine he was the most distinguished graduate of his year, being awarded the Baxter and the Ettles Scholarships in these faculties respectively, and the University medal in medicine and obstetric medicine. After graduation he became house-physician to the late Sir Thomas Grainger Stewart at the Edinburgh Royal Infirmary, and, while Stark Scholar in clinical medicine, worked in the laboratory of the late Professor Greenfield, to whom he for a short time acted as assistant in the pathological department of the university. Soon afterwards he came to London, where he held many hospital and other medical posts, including a house-physicianship at Brompton and the senior medical registrarship at King's College Hospital. He became a member of the Royal College of Physicians of London in 1893, and in the following year was appointed assistant physician to the Royal Hospital for Diseases of the Chest. During his long connexion with the Prince of Wales's General Hospital at Tottenham he served also as lecturer in medicine at the North-East London Post-graduate College. His other activities included the chairmanship of Council of the Women's Imperial Health Association of Great Britain; he was an officer of the French Academy.

A colleague—"W. E. C. D."—writes: "At the time of his death Dr. Murray Leslie was senior physician to the Prince of Wales's Hospital, and had just resigned a similar position at the Royal Chest Hospital, City Road, the amalgamation of which with another hospital and the consequent loss of its traditions and identity as the oldest hospital for diseases of the chest in the world he keenly regretted. In the course of his career he made many contributions to medical literature, and had just completed a volume on *Pneumonia and its Modern Treatment* for Oxford Medical Press. He was widely recognized as a consultant upon diseases of the chest, and patients were sent to him for advice from all parts of the kingdom. Many of his brother practitioners and their patients and all of his hospital colleagues will miss his kindly, loyal, and generous personality. His services were ever freely at their disposal, as well as at that of members of the nursing profession, in the welfare of which he took a deep

and active interest. A few years ago Dr. Murray Leslie founded a medal in Edinburgh University, in honour of his mother, the idea being suggested by the fact that, of her three sons who were members of the medical profession, three were graduates in medicine of the university. Only last year Dr. Murray Leslie married Gladys Olive, daughter of Captain Knox Keith, R.N., with whom deep sympathy is felt.

We regret to record the death of Dr. GEORGE PHILLIPS FRANCIS of Brecon, which took place on February 22nd, after a protracted illness, at the age of 65 years. The son of the late Mr. Charles Francis of Venny-Fach, near Brecon, he was educated at St. Thomas's Hospital, and after qualifying in 1879 held a resident appointment at the City of London Hospital for Diseases of the Chest. He then went into private practice in Boston, Dorset, where he remained for some seven years, and in 1886 he bought an old-established practice in Brecon, South Wales, where he subsequently led a busy and successful life. He was honorary surgeon to the Brecon Infirmary, and held many other medical posts in the district. A member of the Brecon Town Council for some years he twice served as mayor, and, like his father before him, he was a justice of the peace for the borough and county. He was an ardent Freemason, a stalwart Conservative, and a keen member of the British Medical Association, having attended the annual meetings ever since he qualified. Dr. Francis was a man of varied interests, perhaps more fond of a good horse than of anything else, and he was well known as a breeder and exhibitor of Welsh cobs and hackneys. On many occasions he won first prizes at the principal horse shows in England and Wales, including a first at the London Hackney Show, for the best pair in a class open to the world, with the celebrated "Lady Dandy" and "Royalty." The strain of the extra work which he undertook during the war brought on acute dilatation of the heart early in 1919, and, although he resumed work some months later, he never quite recovered. He is survived by three sons, the second of whom, Captain Cyril Francis, R.A.M.C., is at present serving with the Army of Occupation in Germany.

Dr. CHARLES WEBB ILIFFE, coroner for Coventry and North Warwickshire, died on March 1st in his 77th year. He received his early education at the old Grammar School at Coventry, and subsequently studied for the medical profession at Middlesex Hospital. He took the diplomas of L.R.C.P. Edin. and M.R.C.S. Eng. in 1865. He was appointed coroner in 1879. For sixteen years he was surgeon to the Coventry and Warwickshire Hospital, afterwards becoming honorary consulting surgeon. Last year he was appointed a Justice of the Peace for the City of Coventry.

The Services.

HONOURS.

TERRITORIAL DECORATION.

THE KING has conferred the Territorial Decoration upon the following medical officers:—*Army Medical Service*: Colonel Alexander D. Sharp, C.B., C.M.G. *Royal Army Medical Corps*: Lieut.-Colonel Thomas Donovan, 1st Welsh Field Ambulance; Lieut.-Colonel Alexander Callam, D.S.O., 2nd East Lancashire Field Ambulance; Lieut.-Colonel Richard W. Binnacole, Home Counties Casualty Clearing Station (ret.); Major Leonard A. Avery, D.S.O., D.A.D.M.S., 54th (East Anglian) Division; Major John Owen, attached Lancashire Fortress R.E.; Major George Mackie, D.S.O., 1st South Midland Field Ambulance; Major Walter G. Paget, attached 4th Battalion The Queen's Regiment; Major Charles A. Spooner, 2nd London Sanitary Company.

DEATHS IN THE SERVICES.

DEPUTY INSPECTOR-GENERAL NICHOLAS THOMAS CONNOLLY, LL.D., R.N. (retired), died at St. Jean de Luz, France, on February 10th, aged 82. He took the L.R.C.S.I. in 1850, entering the navy soon after, became fleet surgeon on September 25th, 1883, and retired with the honorary rank of D.I.G. on February 11th, 1894. He served in East Africa in the campaign at Vittoria in 1890, receiving the medal with a clasp. Lieut.-Colonel Edgar Ross Russell, Bengal Medical Service (retired), died on November 8th, the day after attaining the age of 72. He was the son of the late Rt. v. Edward Russell, Wesleyan Church, of Bloxwich, Staffordshire, was educated at

Guy's, and took the diplomas of L.S.A. in 1870 and M.R.C.S. in 1872, also graduating as B.Sc., with honours, and M.B., in 1872, at London University. Entering the I.M.S. as assistant surgeon on March 30th, 1872, he became surgeon lieutenant-colonel after twenty years' service, and retired on August 27th, 1900. Almost the whole of his service was spent in civil employment, first in Assam and afterwards in Bengal, where, after various less important posts, he was successively at Patna, and Dacca, 1894-96. In September, 1894-96, he was professor of materia medica in the Calcutta Medical College, and second physician to the college hospital, holding the chair till his retirement. He was the author of a work on *Malaria and the Spleen*, published in 1890.

Medical News.

THE annual general meeting and dinner of the Cambridge Graduates' Medical Club will be held on Thursday, April 21st, at the Imperial Restaurant (Oddenino's), Regent Street, London, W., at 7.30 o'clock, with the President, Sir Humphry Rolleston, K.C.B., in the chair. Price of dinner, 12s. 6d., exclusive of wine. The honorary secretaries are Mr. R. Davies-Colley, C.M.G., 10, Devonshire Place, W.1, and Mr. W. H. C. Romanis, 8, Harley Street, W.1.

A MEETING of the Society of Medical Officers of Maternity and Child Welfare Centres will be held on Friday, April 15th, at 5.30 p.m., in the Central Committee Room, University College, Gower Street, London, W.C., when a paper will be read by Dr. Marion Cockerell entitled "Infant feeding after the ninth month." A discussion will follow. Members are invited to bring friends, provided that they are medical officers of centres.

MEMBERS of the medical boards, the medical referees and the medical staff of the Ministry of Pensions in the Ireland South Region, entertained Dr. D. A. Carruthers at luncheon on the occasion of his departure from the Region. He has held the position of Commissioner of Medical Services for the past two years. About forty members of the medical profession engaged in the various branches of work in the Ministry of Pensions in the Region were present. Drs. C. R. Kilkelly (in the chair), T. E. Rainsford, H. B. Beatty and R. J. Rowlette each expressed the esteem in which Dr. Carruthers was held by the various departments over whose work he has presided, and referred to the invariable courtesy and consideration displayed by him towards all sections of the medical profession who came into contact with him. A presentation and address subscribed by seventy medical men was made in token of the universal regret felt on the departure of Dr. Carruthers from Ireland, and of the good wishes for his future prosperity in his new sphere of work in England. A presentation has also been made to Dr. Carruthers on behalf of the clerical staff of the Medical Services Branch.

A MEETING of the Harveian Society will be held at the Town Hall, Harrow Road, Paddington, on Thursday, April 14th, at 8.30 p.m., when Mr. Duncan Fitzwilliams, F.R.C.S., will read a paper on "The naevi of children and their treatment."

A SPECIAL course of instruction in venereal diseases for post-graduates and students will be given at the London Lock Hospitals commencing on April 18th and terminating on May 10th. The course consists of clinics daily and twenty-five lectures, three of which will be given at the Female Hospital, Harrow Road, and the remainder at the Male Hospital, Dean Street, W. The fee for the complete course is 4 guineas. Applications for tickets should be made to the Secretary at the Hospital, 283, Harrow Road, W.9.

ON March 29th Dr. John Jeffrey of Jedburgh was presented by his patients and friends with an illuminated address and three valuable pieces of Georgian silver on the occasion of his leaving the town to take up an appointment at Aberdeen under the Ministry of Health.

THE annual meeting of the Chartered Society of Massage and Medical Gymnastics will be held on Saturday, April 16th, at 3 p.m., at the Armitage Hall, 224, Great Portland Street, W.1. The chair will be taken by Sir E. Cooper Perry, M.D.

A POST-GRADUATE course in hydrology, radiology, and physical therapy lasting for two months will be held in the course of the year at Naples. Particulars may be obtained from Professor Pio Martori, Sant' Andrea delle Piane 21, Naples.

THE late Sir John W. Byers, Professor of Midwifery in Queen's University, Belfast, left £51,068.

DR. A. T. NANKIVELL, on his retirement from the posts of medical officer of health and school medical officer for Poole, has been presented by the staffs of the health and education departments and of the Alderney Isolation Hospital with an inscribed clock, as a mark of their esteem and respect.

AT the meeting of the Medico-Legal Society, to be held at 11, Chandos Street, W.1, on Tuesday, April 19th, at 8.30 p.m., a paper will be read by Mr. W. G. H. Cook, LL.D., on "The liability of the insane in respect of civil wrongs."

THE King has appointed Colonel Sir Edward Scott Worthington, K.C.V.O., C.B., C.M.G., to be a Companion of the Order of the Indian Empire, for services rendered in connexion with the visit of H.R.H. the Duke of Connaught to India.

A SPECIAL course on the pathology and clinical aspects of tuberculosis will be held at Genoa from April 18th to May 21st. Admission to the course can be obtained on application to the Secretary of the Medical Clinic, Via Balilla 5, Genoa.

THE Coroner for the City of London, Dr. F. J. Waldo, held, during the year 1920, 599 inquiries in the City of London, including H.M. Prison at Holloway and the borough of Southwark. With the exception of a few natural deaths juries were summoned in all cases, Dr. Waldo holding that an intelligent jury, directed by a coroner, is a more satisfactory tribunal for the elucidation of truth than a coroner sitting alone. An inquest was held on the body of only one infant accidentally suffocated whilst in bed with its parents—the lowest figure ever recorded. The marked general decrease throughout England and Wales during the past few years in this class of preventable death is, Dr. Waldo thinks, due chiefly to the more general use of cots and cradles, and the holding of more autopsies by which the actual cause of death is ascertained. Inquests were held in only eight cases in which sudden death was accelerated by the administration of anaesthetics for surgical operations. Of this number, three died in the City and five in Southwark.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Boeilias*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"X." asks: Should a medical man who retired from practice in September, 1917, be assessed on a three years' average for 1920-21, seeing that since retiring he has done only a little locumtenent work?

*. No. If "X." had retired from medical work altogether he would not have been assessable at all for 1918-19 or following years. If he sold his practice his successor was liable to account for tax on the full profits of the tax from September, 1917, onwards, and no doubt did so. In any case, however, it seems clear that from that time our correspondent's income tax liability ceased to have any reference to the profits of his former practice, and that a new basis of liability was set up when he commenced locumtenent work.

"COLONIAL" inquires as to deductions for (1) "the primary cost of necessary instruments, etc.," and (2) "part of the rent of a house a room of which is occasionally used for work."

"(1) The cost of the primary or original equipment cannot be deducted; that cost represents an outlay of capital and only expenditure incurred to maintain the equipment is deductible. (2) "Colonial" can deduct a reasonable proportion of the rent he pays; what that proportion would be would, of course, depend on the particular circumstances.

"T. M. P." is selling a 1919 Ford car and a 1920 motor cycle for £275 and purchasing a new car for £600. He inquires whether he can claim an allowance of the difference.

"As an expense of renewing his means of locomotion our correspondent is entitled to a deduction equivalent to the excess over £275 of the cost price, as on the day he purchased the £600 car, of a 1919 Ford and a 1920 motor cycle of similar make and power.

"BASUTOLAND" inquires what would be the position if his wife came to reside in England.

"She would be liable to account for tax—after deduction of £225 and the allowances for children—on (a) her own income and (b) such portion of our correspondent's income from property (not from earnings) as he remitted to this country. In any financial year in which he is in this country, he would have to account for tax on one-third of the amount of the remittances made by him from earnings in the previous three years. The rates of tax are 3s. in the £ on the first £225 of taxable income and 6s. in the £ on the balance.

PAIN IN THE SHINS.

"W. M. J." desires suggestions for the diagnosis and treatment of a case under his care. The patient is a man of 55, who has suffered on and off for some twenty years past from aching pain in the shins at the junction of the tendinous and muscular portions of the exterior muscles of the leg. The pain usually comes on in one leg or the other after three or four hours in bed and awakens him from sleep. The skin over the affected area is cold to the touch. The patient is sparely built, but appears healthy and complains of nothing else. He takes a fair amount of walking exercise, wearing heavy boots and leggings. There is unquestionably no history of syphilis. I supposed that the condition was due to digestive disturbances and particularly to the use of acid fruit, etc., but am not clear if this is the case.

LETTERS, NOTES, ETC.

TRANSFIXION OF THE BODY.

DR. S. D. CLIPPINGDALE (London, W.) writes: The remarkable case now in Charing Cross Hospital—a man whose body was transfixied by a long metal rod (cleverly removed with the help of Mr. Venables, the hospital engineer)—is not without historic precedent. In the *London Hospital Gazette* for March, 1913, in a memoir of Sir William Blizard, I referred to a similar case which occurred about a century ago. A gentleman drove in a one-horse chaise from his office in the city to his home in Stratford. On arriving he found his groom absent, and had to unharness the horse himself. The horse, resenting the attention of a person to whose services he was not accustomed, became restive and impaled his owner to the stable door by driving one shaft of the chaise right through the chest. The local doctor, Mr. William Maiden, M.R.C.S., called in, sent for Sir William Blizard. Sir William, who practised long before the days of antiseptic surgery, was well aware of the danger of admitting atmospheric air into wounds, and advised the local surgeon to content himself with sawing off the projecting ends of the impaled shaft, and not attempt to remove it. This was done. The patient lived twelve years, and in gratitude for the action, or rather inaction, of his surgeon bequeathed his thorax with the shaft in it to the Museum of the Royal College of Surgeons. In the library of the college is a full account of the case by Mr. Maiden.

PUERPERAL INFECTION.

"M.D." (Lancs.) writes: It is a remarkable fact that when I get infection in any of my cases a certified midwife has invariably been in attendance; when the case has been attended by a woman neighbour the cases do well. Why is this? A midwife makes at least one examination, if not more; a neighbour does not make any. I find also that it is common for midwives to have patients with mild degrees of septicaemia, who recover without medical assistance. They hesitate to call in a doctor for two reasons: (1) It might convey to the minds of the relatives the midwife's incompetence, and (2) they dread a notification of puerperal fever. If the inspector of midwives would pay surprise visits and take the temperatures of all cases on the list of a midwife he or she would sometimes receive a shock.

ERADICATION OF TUBERCULOSIS IN MAN AND ANIMALS.

DR. A. A. WARDEN (Paris), in the course of a letter on the report of the combined meeting of the Royal Society of Medicine and the Central Branch of the National Veterinary

Medical Association published in our issue of March 19, writes: From Sir John McFadyrean's remarks (p. 422) I gather that the eradication of tuberculosis from cattle would reduce to a vanishing point tuberculosis in other domesticated species, and appreciably reduce the incidence of tuberculosis in man, seeing that (Dr. A. C. Tuman, p. 423) 18.7 per cent. of all cases are bovine infections and 85.7 per cent. of cases in children under five are of bovine origin. Sir John goes on to say that the eradication of tuberculosis would involve the slaughter of 750,000 cows or heifers, and that no Government would find the money to compensate for such a slaughter and the consequent diminution of the supply of (tuberculous?) milk. Rounding off the above figures a little, we may say, without undue exaggeration, that 25 per cent. of the tuberculosis in Great Britain is due to tuberculous cows and could be eradicated by their slaughter. Averaging the tuberculous cow or heifer at £10, we may conclude that, for lack of £7,500,000, one-quarter of that section of our population now doomed to tubercle, some 25,000 lives, mostly of infants, must be sacrificed, will be sacrificed this year, next year, every year. Easily satisfied, indeed, must we be if we accept Sir Clifford Allbutt's cold and paradoxical comfort that, after all, tuberculosis has brought us benefits in its train, and that our hope must lie in team work with comparative pathologists; and resign ourselves to his assurance that, in such a struggle, the public would bestow a relatively small sum for investigation and expect results in three months.

SIMULIUM REPTANS IN IRELAND.

DR. NINIAN M. FALKNER, Vice-President R.C.P.I. (Dublin), writes: Some time since I received from the late Dr. Cecil Digby of Knockane (on the banks of the river Lanne), co. Kerry, a fly, the bite of whose bite, he stated, produced severe . . . in man and in animals. I forwarded . . . Halbert, of the entomological department of the National Museum, who identified it as a specimen of *Simulium reptans*, described by Mr. Austen as one of the most dreaded of the blood-sucking Diptera. As the existence of this fly has only been recorded from a few Irish localities, some of which need verification, the foregoing may be of interest to your readers.

AN ACID DENTIFRICE.

DR. H. W. COLLIER (London, E.C.) writes to express his agreement with Dr. W. J. Henson's letter in the *JOURNAL* of March 12th, p. 408, regarding the injurious effects of the various alkaline dentifrices now in the market and the advantages of a fruit-acid toothpaste.

A DISCLAIMER.

WE have received a note from Dr. R. L. Mackenzie Wallis and Dr. C. Langton Hower stating that articles which have recently appeared in the lay press, purporting to be abstracts of a paper recently read by them at the Royal Society of Medicine on a new anaesthetic, were published entirely without their knowledge and permission.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33.

THE following vacant appointments of certifying factory surgeons are announced: Catwick (York, East Riding), Duntocher (Dumbarton), Eastbourne (Sussex), Sedgely (Stafford), Sherborne (Dorset), Stanford le Hope (Gloucester).

WE have received from Messrs. Watson and Sons (Electro-Medical), Limited, the latest issue of their *Sanic Record*, which contains a useful chart and table of spark-gap voltages, and also a bulletin on the use of duplitized film—that is, an x-ray film which has an emulsion coated on both sides—and its manner of development. This firm has lately placed on the market a new x-ray plate in which an intensifying-screen material is combined with the emulsion so as greatly to reduce exposures.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	9	0
Each additional line	0	1	6
Whole single column (three columns to page)	7	10	0
Half single column	3	15	0
Half page	10	0	0
Whole page	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

425. The Epidemiology of Acute Nephritis.

PETREN (*Acta Medica Scandinavica*, January 14th, 1921) notes that though none of his patients had taken part in the war and could not therefore be suffering from trench nephritis, he has found a considerable increase in the number of cases admitted to his hospital with acute nephritis in the past few years. Thus, in the five-year period 1912-1916 inclusive, he saw only 28 cases, whereas in the two-year period 1917-1918 he saw as many as 32. In none of these cases was the nephritis due to scarlet fever, and in the period under review no alterations were made in the rules governing the admission of patients with acute nephritis to hospital. Hence the author's inclination to refer this sudden rise to that vague, unilluminating factor, *genius epidemicus*. He has studied 36 cases seen between 1917 and June 1st, 1919, with a view to classifying them according to the system of Volhard and Fahr, who distinguish two main classes: (1) Acute glomerulo-nephritis with high blood pressure, red cells in the urine, and no oedema; and (2) acute nephrosis with oedema, but without a rise of blood pressure or red cells in the urine. The author found his own cases could not thus be docketed, and he is sceptical as to the value of this classification.

426. Pulmonary Syphilis.

ACCORDING to BERISSO and ADELAIDI (*Rev. Sud-Amcr. de Endocrin.*, January 15th, 1921), who record twelve cases in patients aged from 38 to 60, preliminary syphilis almost always occurs in the third stage, and rarely in the secondary stage, in which acute symptoms of bronchitis, tracheitis, and laryngo-tracheitis are much commoner. Two main forms of pulmonary syphilis may be described, namely, acute and chronic. In the acute form, which is rare, the patient is suddenly seized with symptoms simulating pneumonia or bronchopneumonia, such as high fever, profuse sweating, cough, and blood-stained expectoration. In such cases the diagnosis is made by bacteriological examination of the sputum. The chronic form is subdivided into (a) a gummatous form resembling tumour of the lung; (b) a form simulating chronic pulmonary tuberculosis; (c) a form with chronic pneumonia which may occur either as caseous pneumonia or as pneumonia with a tendency to fibrosis; (d) a form associated with bronchial dilatation—a very frequent variety; (e) a form characterized by pleurisy, usually dry in character; (f) a form accompanied by tracheo-bronchial adenopathy; (g) forms with other visceral lesions—for example, in the liver, stomach, intestine, and spleen; (h) forms complicated by pulmonary gangrene; (i) forms associated with pulmonary tuberculosis, which occurs in a high percentage of cases; (j) asthmatic forms. All the writers' patients, with the exception of one fatal case, were benefited by specific treatment. The best results were obtained in the sclero-gummatous form, and then in the bronchiectatic, pleural, asthmatic, and caseous forms.

427. Renal Decapsulation in Subacute Nephritis.

BOYD, FOWLER, SIMPSON, and FRASER (*Edin. Med. Journ.*, February, 1921) record their experience of the value of renal decapsulation in subacute and chronic nephritis in adults and children. Cases of chronic parenchymatous nephritis appear to benefit by decapsulation more than chronic interstitial cases. By producing diuresis relief may be obtained, but the operation only relieves symptoms and does not abolish the albuminuria. Decapsulation of one kidney appears to afford sufficient relief and is preferable to a double operation at one sitting, it being better to wait for the second operation until the first has been recovered from. The operation should be considered in all bad cases which are not improving after full trial of medical treatment. Catheterization of the ureters proves that the kidney so operated upon functions better than the other. In children, stripping one kidney often relieves all symptoms for a time though the albumin continues, whereas a second operation on the other kidney offers a prospect of cure. In cases of subacute nephritis where the patient is going downhill in spite of all other treatment, decapsulation, by producing diuresis, may cause an improvement in the general condition of the patient, as shown by diminished oedema and a fall in the soluble nitrogen of the blood.

428.

Hyperthyroidism.

MORRIS (*Med. Record*, January 22nd, 1921) urges the importance of diagnosing hyperthyroidism before the disease has progressed to the terminal stage. In making an early diagnosis the estimation of the basal metabolism, the adrenaline tests, and the glucose tolerance test are most useful, especially in making a differential diagnosis between hyperthyroidism, early tuberculosis, neurasthenia, D.A.H., etc. In hyperthyroidism the metabolic rate is always increased in direct proportion to the amount of thyroid intoxication. The hypodermic injection of 8 minims of a 1 in 1,000 solution of adrenaline increases both pulse rate and blood pressure, followed by a fall and then a secondary rise, with a return to normal in about an hour and a half, and such injection causes an exaggeration of symptoms. These cases have a low glucose tolerance, a hyperglycaemia following the ingestion of 100 grams of glucose, even in borderline cases. X-rays or radium in conjunction with medical treatment give excellent results, the use of surgery being mainly when other measures fail, and when pressure symptoms or malignant degeneration of the thyroid occur, or in removing causes of hypersecretion.

429. Radiotherapy of the Endocrine Glands.

ACCORDING to BÉCLÈRE (*Paris méd.*, February 5th, 1921) there are at present only three glands of internal secretion—namely, the thyroid, thymus, and hypophysis—that are suitable for radiotherapy. As regards the thyroid, radiotherapy is the best treatment for Graves's disease and more generally for all forms of hyperthyroidism. Enlargement of the thymus giving rise to permanent or paroxysmal dyspnoea, cyanosis, and syncopal attacks, is better treated by this method than by thyrectomy. As regards the hypophysis, hypopituitarism, which is manifested by Frölich's adiposo-genital syndrome, requires pituitary otopherapy, whereas hyperpituitarism and pituitary tumours, in the absence of syphilis, is an indication for radiotherapy. Treatment of arterial hypertension by radiotherapy of the suprarenals, as suggested by Zimmerman and Cottenot, does not appear to justify the employment of the method in practice. No radiotherapeutical investigations have hitherto been made on the pineal gland.

430. A Sign of Cerebro-spinal Meningitis.

EDELMAAN (*Wien. Klin. Woch.*, November 25th, 1920) describes the following sign which he has observed at an early stage of cerebro-spinal meningitis. On flexing the leg at the hip-joint with the knee extended, as in eliciting Lasègue's sign, dorsal flexion of the great toe frequently occurs, as in Babinski's sign. The sign is met with in senile cerebro-spinal meningitis, in which nuchal rigidity and Kernig's sign are sometimes absent. It is also present in cases of cerebral oedema.

431.

Epidemic Hiccough.

HOUTST (*Nederl. Tijdschr. v. Geneesk.*, February 12th, 1921) emphasizes the fact that none of the patients with this condition feel ill but are able to carry on their daily occupation. As regards treatment, he does not think that vertical pressure on the cricoid, which has been recommended, is of any use, but he advises pressure over the supraclavicular fossa, where one is more likely to reach the phrenic nerve. He has had considerable success from the use of a combination of the bromides in the form of Charcot's solution, a teaspoonful of which is given every two hours until the hiccough ceases. McWalter, who reported a small outbreak of hiccough in Dublin, found intranasal applications of chloroform, camphor, and olive oil of much service.

432. Myeloid Leukaemia Treated with Benzol.

STREXON (*Lancet*, January 15th, 1921) reports a case of myeloid leukaemia successfully treated with benzol. The woman, aged 37, had been ill about two years and presented typical signs of the disease, with an enormous spleen and 200,000 leucocytes and 3,000,000 red blood corpuscles. She had been treated for a year with arsenic, splenic otopherapy, and for six months with x-rays, but without any benefit. On February 1st, 1918, benzol was given, and eight weeks later there were only 15,000

leucocytes and the red corpuscles had gone up to 4,000,000, with great improvement in general health. Benzol was administered for three months altogether, and in that time 354 grams were given in all. As the patient left the country at this time, the further development of the case was unknown, but as far as it went it seemed conclusively favourable. The author has collected nineteen cases treated with benzol, and all showed definite improvement. Abnormal or pathological white cells seem to be destroyed by benzol and abnormal increase of leucocytes checked. In the leucolytic process auto-leucolysis are generated which tend to keep down the number of leucocytes. The myelocytes are peculiarly sensitive to the action of benzol.

433. Insomnia as a Sequel of Lethargic Encephalitis.

ROASENDA (*Il Policlinico*, Sez. Prat., February 7th, 1921) records 3 cases in patients aged 35, 36, and 5 respectively, who, after an attack of lethargic encephalitis, presented an inversion of the natural rhythm of sleep. Instead of sleeping during the night and remaining awake during the day they enjoyed a fairly good and refreshing sleep from early morning until late in the day, but were tormented by insomnia with psycho-motor agitation during the night. The insomnia was not affected by any of the usual remedies, but persisted indefinitely.

434. Reed Dermatitis.

TIMPANO (*Il Policlinico*, Sez. Prat., January 3rd, 1921) states that this condition, which is met with among reed workers, usually affects the forehead, eyelids, cheeks, nose, antero-lateral parts of the neck, back of the hand, and scrotum. The skin is swollen and reddened without a distinct edge; occasionally vesicles are found containing a fluid with a few red corpuscles. The patient complains of smarting and itching. Usually there is no general disturbance, but occasionally there is a rise of temperature of varying intensity, and sometimes albuminuria. The conjunctiva is often affected, and presents hyperaemia, photophobia and lachrymation. The nasal mucous membrane may also be involved, when there is itching, smarting, and in severe cases frontal headache. The prognosis is favourable. Treatment consists in rest, soothing ointments, such as oxide of zinc, salicylic acid, ichthyol, etc. The dermatitis clears up in a few days without leaving any trace. Clinical observation and laboratory experiments carried out by Timpano have shown that reed dermatitis is due to the chemical action of the black powder contained in the leaves of old reeds, the powder acquiring pathogenic properties owing to special changes which it undergoes in course of time and as the result of damp.

SURGERY.

435. Removal of Suprarenal Capsules for Epilepsy.

FISCHER has shown by his animal experiments that the removal of the suprarenal capsule diminishes susceptibility to convulsions and reduces muscle tonus. Fischer believes that the central nervous system plays only a subsidiary rôle in epilepsy, the vegetative nervous system and the organs of internal secretion being of prime importance. This would explain the ill success which has attended operations on the brain for the cure of epilepsy. BRUENING (*Zentralbl. f. Chir.*, October, 1920), with Fischer's work in his mind, has applied the principles to man and has excised the left suprarenal capsule from nine patients suffering from epilepsy. He describes the technique in some detail. The organ is approached by the abdominal route. The left adrenal is that chosen because, although the right lies lower, there is danger of wounding the biliary passages or tearing the liver. Bruening makes for the lower border of the pancreatic tail after pulling the colon well down and perhaps mobilizing the splenic flexure. The kidney is depressed and the fatty capsule dissected from the suprarenal, which is removed after picking up its vessels. Drainage is only instituted if haemostasis has not been satisfactory. All the patients recovered. The dissection is a deep one, and long instruments are necessary. In two cases, where fits were a daily occurrence, there have been no further convulsions. In all the others there was improvement, sometimes a very great improvement. Bruening is encouraged by this method of treatment. The cases were unselected, and one at least (an old encephalitis) was unsuitable for operation. He believes that the best time for interference is after puberty, when growth is finally slowing down. His two successes were in patients aged respectively 18 and 21 years. He

admits that this question of the influence of the sympathetic system on the brain is in its infancy, and contemplates the necessity for removal of the right suprarenal as well. Accessory adrenals and compensatory hypertrophy of the remaining adrenal tissue are possible causes of failure which require investigation.

436. The Treatment of Tuberculous Empyema.

SAUGMAN (*Hospitalstidende*, January 19th, 1921) notes that only a few years ago tuberculous empyema was usually treated like other forms of empyema by incision, costal resection, drainage, and aspiration of the pus through a drain. Although of late fashion has swung in favour of conservative treatment, the practice is still all too common of draining a tuberculous empyema—a practice which the author stamps as a malpractice. Not only does he recommend conservative treatment with simple gas replacement after aspiration in pure tuberculous empyema, but also in many cases of mixed infection. He has found it possible to aspirate even several litres of pus at one sitting, and to replace it by a slightly smaller quantity of air without the slightest inconvenience to the patient, who was, indeed, much relieved thereby. This replacement can be repeated as often as the operator likes, and in cases of mixed infection can, if necessary, be supplemented by irrigation of the pleural cavity with saline or antiseptic solutions. Even in the most septic mixed infections this comparatively conservative treatment should be given a fair trial before the surgeon resorts to incision and free drainage.

437. Pain on the Left Side in Appendicitis.

ACCORDING to HAMANT (*Rev. méd. de l'Est*, January 1st, 1921), who records an illustrative case in a girl aged 13, pain on the left side in appendicitis may be primary or secondary. When it is primary, it is due to the appendix being situated on the left side. The organ may be so displaced under three different conditions: (1) inversion of all the organs; (2) the caecum and appendix, as the result of ptosis or through their possessing a long mesentery, take up their position on the left side of the abdomen; (3) the appendix being abnormally long becomes attached to the left iliac fossa or its immediate neighbourhood. Much more frequently the pain on the left side in appendicitis is only secondary, and is due to an extension of an inflammation or suppuration originating on the right side.

438. Gunshot Wounds of the Mastoid.

LANNOIS and SARGNON (*Ann. des mal. de l'oreille*, Nos. 10-12, 1914-1915), who record 38 illustrative cases, state that fractures of the mastoid, which were relatively rare in previous wars, were more frequent in 1914 owing to the nature of trench warfare, in which wounds of the skull, face, eyes, and ears were much commoner than before, as the result of use of bombs. The prognosis of operation in simple cases is very good and the mortality nil, healing taking place by first intention. The complicated cases may be divided into six classes according to the following complications: (1) lesions of the pinna and external auditory meatus; (2) suppurative otitis media; (3) mastoiditis; (4) complete peripheral facial paralysis; (5) deafness; (6) neighbouring lesions (skull, face, eyes, large vessels).

Acoustic Nerve Tumours.

439. DE MARTEL (*Bull. Mém. Soc. de Chir. de Paris*, November, 1920) describes his present-day technique when operating upon tumours of the acoustic nerve. He remarks that the results of operations upon these cases have been so bad that the physician who sees the cases is chary of handing them on to the surgeon. He has recently had three successes out of five attempts, and claims that these are the first cases of recovery after operation published in France. De Martel uses Cushing's technique with two variations. He has the patient in the sitting posture astride a chair, with his forehead resting on the arm, and infiltrates with novocain instead of giving a general anaesthetic. He thinks that these two points are of great value, as haemorrhage is less and the patient is able to aid the surgeon by moving the head when required and rendering the pontine angle more accessible. These tumours are usually small, occupy the cerebello-pontine angle, and early produce deafness.

Foreign Body in the Heart.

440. ROCCAVILLA (*Riv. Osped.*, December 31st, 1920) records the case of a soldier wounded in 1918 by a bullet in the precordium. When seen in 1920 the radiogram showed the presence of a foreign body in the wall of the right ventricle. The patient showed symptoms of limited soft pericardial adhesions, and presented disturbances of the

rhythm of the heart with pulsus alternans and respiratory disturbances. Wounds of the heart may be grouped into (1) cases where the projectile can be removed at once; (2) cases where the projectile has shifted from its first position in the heart, along the vessels, or vice versa, from the vessels to the heart cavities; (3) cases where a projectile remains in the heart without causing any serious trouble; (4) rare cases where the wound or the retention of the foreign body is followed by functional disturbances of the valvular orifices, of the cardiac rhythm, or auriculo-ventricular conduction. The case recorded by the author belongs to the fourth of these groups.

441. Carcinoma of the Duodenum.

CARCINOMA of the duodenum is one of those rare diseases—probably of commoner occurrence than is generally believed—which one meets with from time to time. MCGUIRE and CORNISH (*Ann. Surg.*, November, 1920) saw two cases within a few days of one another. The pre-operative diagnosis is usually wrong, practitioner and surgeon alike mistaking the disease for pyloric carcinoma. If the proximal duodenum is affected, such an error is almost unavoidable. Many cases of cancer of the ampulla of Vater or of the terminal bile and pancreatic ducts are wrongly described as being duodenal carcinoma. In these the duodenal involvement is secondary. Jaundice is a prominent sign in these cases. McGuire and Cornish publish two examples of this condition to contrast with true duodenal carcinoma.

442. Laryngeal Hemiplegia due to Gunshot Wounds.

COLLET (*Ann. des mal. de l'oreille*, Nos. 10-12, 1914-1915) records 12 cases of this condition, 8 of which were situated on the left side. Of the 4 cases in which the hemiplegia could be attributed to a lesion of the recurrent laryngeal nerve, in 2 there was pure laryngeal hemiplegia, and in 2 laryngeal hemiplegia was associated with paralysis of the brachial plexus. In 3 cases in which the hemiplegia appeared to be due to a lesion of the spinal accessory it was accompanied by other paralytic phenomena, indicating a lesion of neighbouring nerve trunks—namely, lingual hemiplegia in 2 cases, lingual, pharyngeal, and scapular hemiplegia in 1 case, and lingual and pharyngeal hemiplegia in 1 case, accompanied by acceleration of the pulse. In one case there was disturbance of taste due to a lesion of the glosso-pharyngeal nerve. Laryngoscopic examination showed the paralysed vocal cord in the cadaveric position in 4 cases, in 3 of which there was paralysis of the recurrent laryngeal and in 1 of the spinal accessory. In the other cases the vocal cord assumed the median position, but it was not always rectilinear. In 4 cases, which were those with the vocal cord in the cadaveric position, the aphonia was immediate and complete; in one case it was immediate but subsequently improved; in the other cases the vocal impairment, which was also immediate, was not aphonia but hoarseness only, and in one case the aphonia did not develop until some days after the wound. The most important symptom was the intense dysphagia due to paralysis of the vagus and even of the glosso-pharyngeal. As a general rule the prognosis was unfavourable as regards recovery of function.

OBSTETRICS AND GYNAECOLOGY.

443. The Use of Pessaries.

KELLY and FRICKE (*Therapeutic Gazette*, January, 1921), after a summary of the history of the pessary, review its modest place in the gynaecological practice of to-day. They suggest that a pessary is not at all used as formerly, as a mechanical device to correct a displacement; but that its function is simply to take up a certain amount of slack in the vagina and to prevent further downward displacement, to keep the uterus from sagging down on to the pelvic floor, and in this way to relieve the dragging sensation. It is likely to be useful, therefore, in retroflexions with descensus, and for certain cases of prolapse, but not in the antelexions so much pessary-treated by a former generation. The important factor, they consider, is not flexion but descensus, and the vital question, whether or not a pessary is likely to help the patient, hangs on an examination which determines whether or not she has any decided descensus, and this is best revealed by examining in a standing posture. The most useful and best form of pessary, they consider, is the simple ring made of thick rubber—thin ones should be rejected—large enough to stretch the vaginal walls and take up slack, but not to make a tight fit. Soft

rubber and air inflated pessaries, much in vogue still, ought to be discarded, as they provoke irritating secretions, and are a source of infection. The Gehrung pessary is a most serviceable form, they consider, in the group of cases in which the anterior wall of the vagina pouts out. When inserted, it simply rolls over in the vagina and does not tend to escape; it is worn with the cervix resting between the two limbs of its double U. LIL (*Amer. Journ. of Obstet. and Gyn.*, January, 1921) describes the Gehrung pessary and its method of introduction in some detail. He considers it of great value in certain cases, but states that patients find it impossible, and many doctors—unaccustomed to its form—find it difficult, to replace the instrument after removal.

444. Caesarean Section in Infected Cases.

BROUHA (*Gyn. et Obstet.*, 1920, vol. ii, No. 6) discusses the question of whether the operation of Caesarean section should be confined to uninfected cases. From 1914 to 1918, he states, he performed 60 Caesarean sections, and of these cases 12 were uninfected, but the other 48 had been repeatedly examined at their homes before operation, and of these two-thirds had membranes ruptured for periods varying from two hours to five days. His results comprised a mortality of two cases (3.3 per cent.), but both of these cases were uninfected before operation. One of the fatal cases had undergone two Caesarean sections previously, and death was presumably due to shock, following rather severe haemorrhage. The other death was from septicaemia, which the author suggests may have been due to imperfect sterilization at the operation. All of the 48 cases which were more or less infected before operation made excellent recoveries.

445. Alimentary Amenorrhoea.

KURTZ (*Zentralbl. f. Gynäk.*, February 26th, 1921) uses this term in preference to the more familiar one of "war amenorrhoea" in a paper based on observations made at the Berlin Institute for Epileptics. Of 142 women who were interned in this institute throughout the war only 13, or 9.2 per cent. of those aged from 16 to 44, with previously normal menstruation continued to menstruate the whole time. In the remaining 129, or 90.8 per cent., amenorrhoea set in, the onset being most frequent in the fourth quarter of 1916 and first quarter of 1917. There was at the same time a loss of weight amounting on the average to one-eighth of the initial weight. In 40.8 per cent. menstruation reappeared by March, 1920, and in the rest it remained in abeyance. The longest duration of amenorrhoea in cases which had recovered was forty-seven months, the average time being two years, and the longest duration of persistent amenorrhoea was sixty-one months, the average time being three years and two months. None of the causal factors of amenorrhoea mentioned in the literature were present, such as psychical trauma, overwork, and sexual abstinence; but disturbance of nutrition caused by the blockade was alone responsible. In 32 per cent. diminution in the size of the uterus could be detected by palpation. In one case which came to autopsy nothing could be found in the uterine mucous membrane except glandular deficiency. The prognosis did not appear to be so bad as was often stated in the literature. It was most favourable in women between the ages of 26 and 33.

446. A Study of Chronic Endocervicitis.

MATHEWS draws attention (*Surgery, Gynaecology, and Obstetrics*, March, 1921) to the frequency of this condition, and describes in detail the pathology. He makes an interesting suggestion as to the cause of backache associated with this disease—namely, that there is a cellulitis around the utero-sacral ligaments. He considers that the best treatment is undoubtedly the operative, and describes in detail the method of excising a cone of cervical tissue containing the cervical mucous membrane. No complications in pregnancy or labour have been observed to follow this operation.

447. Turpentine Injections for Gynaecological Infections.

FRIEDERICH (*Zentralbl. f. Gynäk.*, March 12th, 1921) summarizes the results, reported from various sources, of the treatment of gonorrhoeal and non-gonorrhoeal inflammations of the urogenital tract, especially in females, by intramuscular injections of turpentine (Klingmüller) or its derivatives (Kleemann, Karol). From his personal experience of this treatment in 22 cases, Friederich concludes that it is more successful in chronic than in sub-acute or acute inflammatory conditions of the adnexa.

In 9 out of 14 of his chronic cases the subjective symptoms had completely, and the objective symptoms almost completely, disappeared after from one to five injections made at intervals of five days; in one case a painful axillary tumour, the size of an apple, had completely disappeared five days after a single injection. In three cases acute inflammatory exacerbations appeared so to respond to turpentine injections as to become quiescent and permit of an accurate diagnosis of hitherto obscure axillary abnormalities, which were then successfully treated by operation. The injections were made close to the bone, three fingerbreadths below the iliac crest in the posterior axillary line. Other writers have recommended injections into the gluteal muscles.

PATHOLOGY.

448.

Development of Bone.

TILLIER (*Lyon Chir.*, July-August, 1920) draws attention to a line of denser bone, parallel to the epiphyseal cartilage, and situated in the juxta-epiphyseal region, frequently to be seen in radiographs of the long bones of children. This line is a perfectly normal characteristic of young bone, and Tillier has conducted a considerable investigation into its meaning. The line is very narrow, traverses the whole thickness of the bone from side to side, and in the author's opinion constitutes a line band of condensation at the boundary of metaphysis and diaphysis. The metaphysis is that part of the bone which lies between the primitive diaphysis and the epiphysis, and probably originates in the deposition of bone on the proximal side of the epiphysis. Tillier notes that the block of cartilage at the end of the foetal bone is in proportion considerably larger than the subsequent epiphysis will be. The effect of ablation of the juxta-epiphyseal bone (metaphysis) causes a definite decrease of growth, not so great as removal of the epiphysis, but much more pronounced than removal of any part of the diaphysis proper. Tillier pleads for the individuality of the metaphysis and reproduces several drawings from x-ray plates to illustrate the special pathology of this region. In rickets, for instance, a series of these lines can often be seen between the epiphyseal cartilage and the extremity of the diaphysis, as if bone had been laid down in the metaphysis in successive layers. In tuberculosis also the shaft seems to be sometimes sealed off by this film of dense bone, the disease involving metaphysis and epiphysis only. The fracture of both bones of the forearm in children occurs at the site of this condensed line, not because the bone is weak there, but because the bony homogeneity is interrupted at that point, and perhaps its elasticity is there impaired.

449. - The Sachs-Georgi Reaction in Syphilis.

ARIAZ and PICO (*Rev. de l'Inst. Bact.*, December, 1920) made a comparative study of the Sachs-Georgi and Wassermann reactions in 240 cases, consisting of 30 cases of tuberculosis, 65 of leprosy, 11 of cancer, 55 of syphilis, and 79 of various other conditions, with the following results. In 390 out of 408 specimens examined, or in 95.43 per cent., the Sachs-Georgi reaction was the same as the Wassermann reaction. In the divergent cases 13 gave a negative Wassermann reaction and a positive Sachs-Georgi reaction. In 4 of these there was no history, 6 were found to have syphilis, and in 3 a positive Wassermann reaction was subsequently obtained by reactivation. In 8 cases the Wassermann reaction was positive and the Sachs-Georgi reaction negative; 2 of these were cases of leprosy, 2 of syphilis, 1 of malaria, and in the rest no data were available. The writers conclude that the Sachs-Georgi reaction is a valuable addition to the sero-diagnosis of syphilis, and should be used as a complementary reaction to the Wassermann reaction. MURSTAD (*Medicinsk Revue*, February, 1921) has compared Sachs-Georgi's reaction with Wassermann's in a series of 314 cases, the serums of which were sent to Gade's Institute in Bergen. The results were identical in 284 cases—that is, in 90 per cent. An investigation of the 13 cases in which the Sachs-Georgi reaction was negative and the Wassermann positive showed that in 8 there was a definite history of syphilis. In the remaining 5 cases there was no available evidence of syphilis apart from the positive Wassermann reaction. Somewhat similar observations were made in the 17 cases in which the Sachs-Georgi reaction was positive and the Wassermann negative; in 9 there was, and in 8 there was not, a history of syphilis. In 6 cases in which specific treatment had been instituted

Sachs-Georgi's reaction was negative, while Wassermann's was still positive; in 8 other cases that had been given specific treatment Sachs-Georgi's was still positive, while Wassermann's was negative. It would seem from these figures that, as a guide to treatment, the value of these two reactions is approximately equal. In 4 cases of lepra tuberosa both reactions were positive, and in one case of lepra anaesthetica both reactions were negative. In a few cases of ulcer molle, miliary tuberculosis, pneumonia, and acute rheumatism, the Sachs-Georgi reaction was positive in the absence of any other evidence of syphilis.

450.

Bilateral Testicular Sarcoma.

ACCORDING TO KAISER (*Wien. klin. Woch.*, December 2nd, 1920), who records an illustrative case, very few examples of bilateral testicular tumour have been recorded. Koehler, in his work on diseases of the male sexual organs, has collected 15 cases in which sarcoma appeared simultaneously in both testes. The metastases usually first involve the retroperitoneal glands and internal organs, such as the liver, spleen, and lungs. Frequently, however, metastases occur by the blood stream, as in sarcoma generally, and tumours appear in the skin and bones. Two factors have been invoked in the etiology of malignant disease of the testes—namely: (1) The tendency of retained or incompletely descended testes to malignant degeneration; and (2) trauma. Neither of these factors, however, could be invoked in Kaiser's case. His patient was a man, aged 54, the father of six healthy children, in whom bilateral enlargement of the normally situated testes occurred without any previous injury. The diagnosis of small round-celled sarcoma having been established by biopsy, both testes were excised. Five months later a recurrence took place in the scrotum, and a metastasis appeared on the skull, but both disappeared under x-ray treatment.

451.

Xanthoma Multiplex.

GAMRAT (*Ann. de Derm. et de Syph.*, November, 1920) gives an account of the microscopic appearances of these interesting lesions. In the nodules there is a mass deposit of lipid substances, amongst which cholesterol predominates. This deposition of cholesterol is definitely limited to the xanthoma nodule, of which it occupies the outer two-thirds; the centre is much less rich in this substance, and here the fibrous tissue is more developed. The infiltration is mainly cellular, the polyhedral and fusiform cells being completely studded with granules, or rather anisotropic droplets. At no part may signs of cellular degeneration be found, so that the presence of the cholesterol is more probably due to a process of infiltration from without than to any degenerative alteration of the cells. An abundant fibrous tissue reaction may be seen in the neighbourhood of the xanthoma cells. A peculiar feature found by Gamrat in all the sections examined was the presence around the capillaries, both within and outside the nodule, of mantles of lipid granules infiltrating their walls. This points to the fact that the cholesterol comes from the blood, which generally, if not always, shows an increased amount of this substance. The granules having traversed the capillary walls may act as foreign bodies and produce a reaction process. Their presence in the cells may be the result of phagocytosis or of absorption by osmosis. The xanthoma cells will then correspond to the so-called "xerophages" which absorb the uric acid crystals in gouty tophi.

452.

The Staining of Phagocytes.

CROSS (*Johns Hopkins Hosp. Bull.*, February, 1921) gives a simple method for the clear and sharp staining of phagocytes which would seem to be desirable. To 100 c.cm. of neutral distilled water there are added 20 c.cm. each of glycerin and alcohol and then 2 c.cm. of phenol. In this fluid there is dissolved, by shaking for two or three minutes, crystal violet 0.05 gram and pyronin 0.2 gram. The stain is ready for use without filtration, and keeps for a long time if shielded from direct sunlight and the bottle is well stoppered. Smears are made on carefully cleaned glass slides and merely dried in the air. The stain is flooded on for five to ten seconds, and thoroughly washed off with distilled water, but direct drying of the preparation by blotting paper is avoided. The nuclei are stained violet and the cytoplasm takes a delicate lavender tint with the cell limits clearly and sharply defined, so that it is easy to distinguish between intracellular and extracellular bacteria, which are coloured deep purple. The chief advantage claimed for the method is that there is a total absence of annoying precipitates which are too often associated with the staining of phagocytes.

Oliver-Sharpay Lectures ON THE NATURE OF FLUTTER AND FIBRILLATION OF THE AURICLE.

BY

THOMAS LEWIS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN OF THE STAFF OF THE MEDICAL RESEARCH COUNCIL;
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON; HONORARY
CONSULTING PHYSICIAN TO THE MINISTRY OF PENSIONS.

LECTURE I.—AURICULAR FLUTTER.*

MR. PRESIDENT,—May I first thank you, Sir, and the College which you represent for the honour you do me in appointing me to this lectureship—a lectureship founded to promote physiological research by observation and experiment and to encourage the application of physiological knowledge to the prevention and cure of disease; a lectureship founded to commemorate a great physiologist, and founded by a physician whose work in this very field is known to and admired by all of us.

The request which you have made, and which I have gratefully accepted, has come at a moment which to me is opportune. This lectureship carries with it a responsibility of no little weight; no lectureship could possess a more serious or far-seeing purpose than the welding together of Physiology and Experimental Medicine. I have said that for me the moment is opportune, for it comes at a time when observations in which I have been deeply interested for many years have grown to a state of some maturity. The observations of which I shall speak are essentially of a physiological kind; the investigations are reaching a point when their applicability to the practice of medicine cannot long remain in doubt. The subject chosen is the only subject which I could choose for these lectures—the work upon which my collaborators and myself have now been engaged for many years, a subject upon which we have been almost exclusively engaged during the past

two years. These researches have comprised an attempt to solve the meaning of certain grave disturbances of the human heart beat, and it is my good fortune to be able to say to-day that we are at the end of this task.

It is a long story, and, if it is to be told intelligibly in these two lectures, it must be told connectedly. With your permission I will try and place before you the leading facts

and arguments; I will narrate these, not in their historical order, but in the order most suited to my purpose, namely, to show you where our knowledge of auricular flutter and auricular fibrillation now stands. If I am to do this in the time at our disposal I shall be unable to bring before you anything but a small part of the evidence upon which our conclusions rest. Assuring you now that I shall draw no conclusion lightly nor without most closely weighing all the evidence, I must, from the force of circumstances, ask you to take much for granted. In another direction, also, and for similar reasons, I crave indulgence. It will be impossible for me suitably to bring into the compass of these lectures the names of many contributors to this field of knowledge. This historical aspect has been dealt with recently and fully in another place. In so far as I have myself contributed during the last two years, I have contributed with my immediate collaborators; we have worked as a team under the auspices of the Medical Research Council; the names of my co-workers are

Dr. Thomas Cotton and Dr. A. N. Drury of this country; Dr. H. S. Fell, Dr. W. D. Stroud, and Dr. H. A. Bulger of the United States, and Dr. C. C. Hiescu of Bucharest. From these introductory remarks I may proceed to my subject.

SOME NORMAL FEATURES OF THE CONTRACTION PROCESS.

Let me first briefly describe the relevant events when normal heart muscle contracts in response to a natural or artificial stimulus. The first event of which we possess knowledge is that it passes into what is termed the state of excitation. By this we mean that the muscle develops a charge, just as a battery develops a charge, and that currents flow through it and the surrounding tissues. The charge is such that the active muscle becomes relatively negative to that which is still inactive, in the sense that the zinc terminal of a copper-zinc battery is negative to the copper. These electrical changes, associated with muscular activity, are of sufficient magnitude to be recorded by means of sensitive instruments, and they yield the pictures now spoken of as electrocardiograms. The electrical change in the muscle is the immediate precursor of contraction: first the muscle becomes excited (or charged), secondly it contracts. The two events are separated in the mammalian auricle by a small time interval of three-hundredths of a second or less.

Now the process of excitation is not simultaneous in all parts of the muscle; it begins at the point first stimulated

FIG. I.—A diagram illustrating the progress of a single wave passing through a ring of muscle as a result of stimulating it at a. The black portion of the ring represents the refractory state, and the figure shows its progress through the ring till it involves the whole (d); later the figure shows its subsidence.

FIG. II.—A second stimulus enters the ring while it is in the condition shown in FIG. I. G. While the first wave is subsiding the second wave spreads.

FIG. III.—A diagram to illustrate the establishment of a circus movement in a ring of muscle. The ring is stimulated in its lower quadrant and the wave spreads to A and to B. At A it is blocked, but from B it continues around the ring. When it arrives at E (the refractory state at A is passing, and so the wave continues to travel around the circle C-10).

* Delivered before the Royal College of Physicians of London, April 12th, 1921.

* That the electrical change precedes the contraction is at the moment the accepted view, though the interval is acknowledged to be very short.

and spreads from this point. Stimulate a point in the centre of a sheet of muscle and the wave spreads concentrically, as does the ripple on the surface of a pond into which a pebble is thrown. It is conducted from one muscle element to the next as a wave, which is termed the wave of excitation. Similarly with the contraction process itself; this also spreads as a wave which accurately follows the course travelled by the wave of excitation. It may be likened to the second ripple on the pond. For our present purposes and to simplify the conception, we may regard these waves as one, signalling itself as it proceeds, first electrically (first ripple), then mechanically (second ripple). When, therefore, I speak of the wave of excitation in the auricle and of the course it takes, you may picture in your minds the wave of contraction without fear of serious misconception. Nevertheless, I should, perhaps, be guilty of inaccuracy if I spoke of the wave of contraction, because our studies have been mainly, though not exclusively, directed to the wave of excitation; for movements of the latter are to be recorded with far greater accuracy than movements of the former.

Movement of the excitation wave is recorded by connecting a sensitive galvanometer directly to the surface of the muscle. As the wave passes the chosen point, the galvanometer yields a sharp deflection, and this may be photographed and accurately timed against the events in some other region of the muscle. I do not propose in the present lectures to enter upon a detailed description of this delicate method, but am content to declare that we can time the arrival of this excitation wave at any point of the muscle surface with such accuracy that the error is no more, usually it is less, than one thousandth of a second; that by using two or more recording instruments simultaneously we can trace out the paths taken by waves of excitation as they travel through the muscle; and that we can estimate very accurately the time lost in the passage from point to point in different circumstances.

The wave of excitation, the first of the contraction process, travels until it involves the whole surface of the muscle; it travels in every available direction until it has exhausted all tracts of responsive muscle. Starting in the centre it travels until it comes to the boundaries; there it ends, for at the boundary it finds no further tracts of responsive muscle through which to pass. Appropriately you may liken the spread of the excitation wave to the flame of a prairie fire. It spreads concentrically wherever it finds inflammable material; it cannot return over its scorched wake, neither can it proceed when it reaches the bounds of the dried acres. The wave of excitation leaves the muscle over which it passes in a non-inflammable, or, as it is termed, refractory state, and that muscle is incapable of carrying a second wave of excitation until its original inflammable state is restored. The period during which this restoration is effected is

called the refractory period of the muscle; in the natural beating auricle of the dog it lasts from a fifth to a tenth of a second; its duration is approximately the same as the duration of the contracted state of the muscle. From these preliminary observations I pass to what may be termed the "ring experiment."

THE RING EXPERIMENT.

The ring experiment was first performed by Mayer in 1908; he used the contractile bell of the jelly-fish and subsequently he utilized rings of muscle cut from the ventricles of turtles. His experiments were repeated and amplified by Mines in 1913 upon rings of muscle cut from the auricles of teleostean fishes. In 1914 both Mines and Garroy reported that they had obtained similar effects in rings of muscle cut from the dog's ventricle.

The experiment from our present standpoint is fundamental; I shall describe it, therefore, in some detail.

Suppose that we stimulate a ring of muscle, such as is depicted in Fig. 1, at a centre point of its lowest quadrant,

and start in it by means of a single shock a wave of excitation. This wave, as soon as it has involved the whole cross section of the ring, develops two crests, which travel rapidly along the two limbs of the circle until, as shown in the serial diagrams (Fig. 1, 1-5), they meet at point *b*, the centre point of the highest quadrant. At the instant the crests meet the whole ring has become involved by the wave; the whole has passed into a state of excitation; it has all become "refractory." When, therefore, the two crests meet at point *b*, movement is

brought to an end; like two waves of flame, two waves of excitation meeting do not override, each crest forms an impassable barrier to the other. The ring of muscle remains in this state of excitation for a period and then recovers. It recovers in the order in which it has become involved, it begins to be "responsive" in its lowest quadrant (at *a*) first of all. The

wave of "responsiveness" travels similarly as two crests along the two limbs of the ring (Fig. 1, 5-8) until they also meet and coalesce at *b*, the centre of the highest quadrant. The ring of muscle has now returned to its original condition; it is once again wholly in the responsive state.

Such is the series of events when the muscle of the ring responds to a single stimulus. If the ring is stimulated by means of slow rhythmic shocks, each shock awakens a like series of events, providing that the intervals between the shocks are amply sufficient to permit recovery. Each stimulus yields a double-crested wave of response, which ultimately involves the whole ring. It will be evident that, if in rhythmic stimulation the second shock falls upon the ring while it is in the condition represented by Fig. 1, 6, a fresh wave may be propagated at *a* before the response to the first shock has subsided at *b*. In such circumstances two waves will

FIG. IV.—Examples of auricular flutter, clinical and experimental. The upper or clinical curve was taken from a patient in whom flutter was continuous. The auricle (P) is beating at a rate of 228 per minute and regularly; the ventricle (R) at half that rate. The ventricle responds to alternate beats of the auricle; the beat of the auricle to which there is no response falls with the beat of the ventricle. The lower or experimental curve shows the end of a period of flutter and the return of the normal rhythm. The first half of this curve is to be compared with the upper curve. During the period of flutter the auricle (P) is beating rapidly and regularly; the ventricle (R) at half the rate. The ventricle responds to alternate beats of the auricle; the beat of the auricle to which there is no response falls with the beat of the ventricle.

FIG. V.—Examples of auricular flutter, clinical and experimental. The upper or experimental curve was taken from a long period of experimental flutter. The auricle (P) is beating regularly at a rate of about 350 per minute; the ventricle (R) curve is from a patient in whom flutter had persisted for many years. The ventricle (R) is beating much more slowly.

be moving through the ring at one time, as depicted in Fig. II, 6-8.

We come now to a different form of reaction; it is that which especially concerns us. It happens when the rate of rhythmic stimulation is raised to a critical point—namely, when the intervals between the shocks are such that each falls on the muscle at a time when responsiveness in this muscle has not wholly recovered. In such circumstances the wave propagated by stimulation may be unable to travel with its usual freedom in all directions. From time to time it is found that a wave propagated from the point of stimulation can pass in one direction only. It starts well enough, perhaps, and reaches two points of the ring *A* and *B* (Fig. III); but at *A* it finds the muscle still insufficiently responsive, while at *B* recovery is more advanced. At *A* progress comes to an end, while at *B* the crest continues to move. Suppose that at this instant stimuli are withdrawn; the conditions are peculiar. Instead of two crests, advancing to meet and interfere,

FIG VI—Three electrograms recorded simultaneously from the auricle, inferior caval, and middle cerebral arteries. The top curve (1) is from the auricle, the middle curve (2) from the inferior caval, the bottom curve (3) from the middle cerebral artery. As each excitation wave passes, it signals itself by means of a sharp upward movement of the three recorders. Recorder 1 moves first, recorder 2 a fraction of a second later, and recorder 3 a fraction of a second later still. The order of excitation is 1, 2, and 3, the wave is passing up the kemia.

there is now but one, and it is free to circulate, for as it comes to each new segment (*C*, *D*, *E*) of the ring it finds this segment excitable (Fig. III, 2 to 4). The single crested wave consequently progresses around the whole ring, and, coming back to its starting point, finds that this muscle also has recovered (Fig. III, 5); it proceeds so long as the conditions remain unaltered; it continues its course as a circulating wave which has no ending (Fig. III, 6 to 10). Thus it has been shown that, the conditions being nicely controlled, the last stimulus of a series may originate, not a single response of the ring, but an unlimited series of responses. Mines saw the wave continue to circulate for minutes. Mayer saw it continue for very many hours; this is what is meant by circus movement; it is constituted by a wave of response which travels continuously along a re-entrant path of muscle.

AURICULAR FLUTTER.

We may now examine a condition of the mammalian auricle, to day called auricular flutter. Flutter as we now understand it was first clearly described in a patient by Hertz and Goodhart in 1909; they studied their case by means of venous curves, showing the auricle to be beating continuously and regularly at a rate of 234 per minute.

Their description was quickly followed by the more ample records of Jolly and Ritchie, and of other writers. The rate of the auricular beating in flutter is from 230 to 350 per minute; the action of this chamber is remarkable, not only for its high rate, but for its regularity. It is to be recognized with the greatest certainty in electrocardiograms, of which examples are shown in Figs. IV and V. The condition is also remarkable because it continues uninterrupted for long periods of time. Sometimes it may occur in short paroxysms, more usually it comes to stay for months or years. Its nature until quite recently has remained altogether mysterious, though very numerous observations have indicated its close affinity to the condition called fibrillation. Thus flutter is often converted into fibrillation by the administration of digitalis. There have been few satisfactory records of a similar experimental condition. The term "flutter" was used by McWilliam as early as 1887; that was in the days when the two conditions flutter and fibrillation were not definitely

FIG VII—A natural outline of a dog's auricle, showing the paths of the excitation wave (broken lines) while the heart beat naturally (solid lines) and during flutter (upper diagram). The numbers indicate the approximate order in which various parts of the musculature received the excitation wave.

distinguished. The first electrocardiograms of experimental flutter—and these curves are alone really distinctive—have been obtained during the past few years. We are now certain that a condition identical with that found clinically may be produced experimentally in the dog's auricle; this we have been taught by clinical and experimental electrocardiography.

In investigating disease there is one well known and most fruitful method of approach: it is to produce in animals a condition identical with that seen in the patient. When this has been accomplished it becomes possible to inquire into the precise nature of the disturbance. If and when that knowledge is obtained, we are in a position to consider rational plans of treatment. As I have related, in the case of flutter of the auricle, the first step has been taken. A continuous and rapid action of the dog's auricle can be produced in several ways, notably by rhythmically stimulating the organ with induction shocks at a rate of 300 to 600 per minute. The auricle is driven rhythmically and rapidly for a few seconds, and the stimuli are then abruptly withdrawn. In a certain proportion of experiments a rapid action of the auricle continues after stimulation has ceased. The rate of the action is not usually that of the rhythmic shocks which produced it.

it; it is usually less. For the moment our chief concern is not the method of producing this rapid and continuous action, but its nature. Its nature is variable, but amongst the after-effects of stimulation a condition identical with clinical flutter is seen from time to time. It is not every auricle which is predisposed to flutter; it is not every stimulation which will invoke flutter in the predisposed organ. That, however, is immaterial, providing that we can produce it, and can be certain when it is produced that it is identical with the clinical condition. The electrical curves, clinical and experimental (Figs. IV and V) leave us with no doubt on this subject; these curves, so delicately analytical, place the conclusion beyond question.

Having produced experimental flutter, we proceed to investigate its nature. The method of investigation consists of mapping out the path taken by the excitation wave while flutter is in progress. A single illustration of method will perhaps suffice. The auricle of a dog has been forced into a state of flutter, as ascertained by electrocardiograms taken by methods comparable to those used clinically. The flutter continues uninterruptedly. Three points are now chosen in the line of the taenia terminalis, and to each of these a sensitive galvanometric recorder is connected. The curves of these recorders write simultaneously (Fig. VI). As the excitation waves flow through the muscle they pass beneath the several contact points, and at each the passage is signalled. The curves, considered together, show that each wave is passing regularly up the taenia from the region of the inferior to the region of the superior cava, and we are able to measure the rate at which it is travelling. This record is published to illustrate the orderly character of the events as the cycles are repeated, and to indicate with what certainty the direction taken by the excitation may be ascertained. Actually a slightly different plan of campaign to that described is usually adopted. It consists of maintaining one lead as a standard and moving a second to various points of the auricle, timing the arrival of the excitation wave at its several parts relative to the standard lead, and finally of its arrival at the several parts relative to each other. To exemplify in a simplified fashion a complete experiment I may use Fig. VII. This figure shows the natural outline of the auricle as it is seen from above. The two appendices project upwards in the diagram; the superior and inferior venae cavae are represented as transected. The figures 1, 2 and 4 in the lower diagram lie on the taenia terminalis. The order of excitation displayed by this animal while the heart beats normally is indicated in the lower diagram by the figures 1, 2, 3, 4, etc. The excitation wave, as is usual when the heart beats normally, starts in the region of 1, the point at which the sino-auricular node or "pacemaker" lies. A little later it is to be found simultaneously at the points marked 2. Follow the numerals and you perceive the course which it takes. It flows simultaneously along the muscular paths which radiate from the region of the node. Thus, it flows down the taenia to the inferior cava; it flows from the base to the tip of the right appendix; it flows through the intra-auricular band to the left auricle, and, still flying from its point of origin, traverses the left appendix from its base to its tip. The wave is not visible as a wave; it travels too fast for that; the whole process of spread occupies the twentieth part of a second.

In the top diagram of the figure is the essential part of the map for the same auricle in a state of rapid flutter. The order of excitation is quite different. The wave is first traced at the inferior vena cava (1) and it passes up the whole length of the taenia (2, 3, 4, and 5). Reaching the top of the taenia it moves around the superior cava and flows through the intra-auricular band (6 and 7) to reach the left auricle. It reaches the left appendix (9), and at the same instant a wave is timed to emerge from the inferior vena cava (9). The question which at once arises is whether this second wave, emerging from the inferior cava and repeating the course (10, 11, 12, 13, etc.) of the first wave, is a new wave or whether it is the continuation of the old one. Is there a succession of regular waves, each arising *de novo* in the inferior cava, or is there a single circulating wave? This question is answered by two considerations. If we propagate a wave artificially from the inferior cava, this spreads equal distances in equal times; it arrives at the two points 4 and 7 simultaneously. That is not the case in flutter; here it passes through

point 4 to reach point 7. But the decisive argument is found in the time relation of the wave; knowing the rate at which it travels along its path (1, 2, 3, 4, 5, 6, and 7) we can calculate how long it should take to move from 7 to 9, and can compare this calculated time interval with the actual interval observed; these are found to be the same within an inconspicuous margin of error. There can be no doubt, then, that we are dealing with a wave which circulates. It circulates in this experiment around a natural ring of muscle formed by the orifices of the two venae cavae. Looked at from above, the movement is in the opposite direction to the hands of a clock. In this instance it completed one circuit in 0.16 of a second; it completed therefore 380 circuits in one minute, and that was the rate at which the auricle beat.

The experiment which I have described is one of several, but it will suffice to illustrate the kind of evidence we possess of circus movement in the auricle. Flutter consists essentially of a continuously circulating wave. The path which this central or re-entrant wave usually takes is the one I have described, but that is not invariable. Sometimes in flutter the course is different; thus, the flow may be clockwise over the same route. In other cases only one cava is encircled; the path is shorter, and the circuits are more quickly completed consequently. In other cases, though these are not so clearly evidenced, the circus movement is around other natural orifices, such as the mitral orifice. These variations are chiefly of consequence because they render the experimental work more difficult; the important conclusion is that the wave can be shown to circulate when the auricle flutters. The proof of circus movement in the auricle is not confined to the class of experiment which I have cited; there is much more evidence that I can now give you; taken as a whole I believe it to be quite conclusive.

Now the wave as a whole is not, of course, confined to the central or re-entrant path; as it passes along this path offshoots are sent through the appendices to their tips, and into all other regions of the auricular muscle. Thus the movements of the whole auricular tissue is controlled by the circulating wave. There is the central or mother-wave, and there are its centrifugal offshoots into the remaining tissue.

Such is flutter as it occurs in the dog; such, therefore, is flutter as it occurs in man. In the dog we may see flutter last for hours; in man it may last, not for hours, but for years. I have known it to continue unceasingly for as long a period as seven years; for all we know it may continue even longer. A single wave continuously circulating for seven years: that, perhaps, may seem to be a remarkable conclusion; nevertheless, it is one we are now bound to accept.

THE FACTORS CONTROLLING FLUTTER.

We have seen that a condition comparable to clinical flutter may be produced in experiment; we have seen that when this experimental flutter is investigated it proves to consist essentially of a circulating wave. We may next consider the precise factors which maintain this circus movement. Refer back to the diagrams of the ring experiment and it will be clear that three factors are involved. They are:

1. The length of the central path.
2. The rate at which the wave travels.
3. The duration of the effective refractory period.

It must be evident that if the wave is to continue circulating a gap must exist between the crest of its advance and the wake of its retreat. As the crest travels it must always find the muscle which it enters in the responsive state. If for any reason the gap becomes closed, the wave will proceed no longer and the rapid action of the auricle will cease. The three factors named, and these alone, will control the length of the gap. The duration of the refractory period at any given point must always be less than the time spent by the travelling wave in completing its circuit; this circulation time depends on the length of the path and the rate of travel. Now the rate of travel from point to point in the dog's auricle beating normally is approximately 1000 mm. per second and the length of the refractory period at normal heart rates is approximately 0.15 to 0.2 of a second. In 0.15 to 0.2 of a second the wave will travel through 150 to 200 millimetres of muscle. On the basis of

these values a circus movement could not establish itself in a ring of muscle of less than 150 to 200 millimetres circumference. But it is known that much smaller circuits than these become established. What is the reason? The reason is that when the anricle flutters, the refractory period is reduced; also the rate of travel is usually reduced. These reductions both occur in response to an increased rate of beating such as prevails in flutter. Both changes facilitate the establishment of relatively short circus movements. The precise relations of the three controlling factors have now received close investigation. They are variable in different circumstances, but may be illustrated by a type experiment. A dog's auricle is fluttering at a rate of 500 per minute. Each circuit is completed in 0.12 of a second. The circuit has a length of 60 millimetres. The rate of travel is not 1,000 millimetres per second, but 500 millimetres per second. The rate of travel is but one-half the natural rate; that is so because the rate of beating is so high that the muscle is hard put to it to conduct the impulses. The length of the effective refractory period is not 0.20 but 0.10 of a second; it has become reduced with the rise of heart rate. The cycle is divided into two parts, a refractory phase of a tenth of a second, a responsive phase of a fiftieth of a second. The crest of the wave is constantly but a fiftieth of a second behind its own wake; it travels behind it at a distance of only 10 millimetres. We have direct and conclusive evidence that these figures may be taken as usually representative of the gap which exists; it is a minute gap, yet upon its existence the continued progress of the wave absolutely depends. To the question of this all-important gap I shall return at a later stage; it is a gap which will command the attention of many workers in the near future, for upon our power to influence its length, our success in treating flutter and, as we shall see, the closely allied condition fibrillation, will very largely depend. If by any means we could close that gap we could bring flutter to an abrupt termination.

CARCINOMA OF THE LARGE INTESTINE.*

BY

J. LIONEL STRETTON, M.R.C.S.,

SENIOR SURGEON, KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

THE treatment of cases of carcinoma of the large intestine is difficult. Most patients are fond of procrastination, especially in conditions where an operation enters into consideration. Time is lost with all sorts of examinations and investigations. X-ray photographs after bismuth meals, examinations and analyses of faeces, of vomit and of urine, and inspection with sigmoidoscopes often fail to reveal the early stages of carcinoma of the large intestine, which could be found if an exploratory examination were performed. I do not deprecate these examinations. They are all links in the chain, but they should neither be spread over too long a period nor have too much weight attached to them. Multitudinous drugs are swallowed; some of them give relief by their soporific action, thereby masking symptoms and assisting the disease to progress unrecognized. Strange diets are tried, and a varied assortment of patent foods is consumed. Spas are visited, baths, massage, and electrical treatment are indulged in; the abdomen is sometimes rubbed with bags of shot; enemata are resorted to; sometimes a course at Plombières. All is of no avail. The progress of the disease continues until the chances of cure by a radical operation are gone.

If abdominal pain with irregularity of the bowels, which is persistent for more than twelve months, were looked upon as sufficient to justify an exploratory operation many of these conditions would be disclosed before it is too late to eradicate them. It is very important to bear in mind that these carcinomata of the large intestine are not so likely to recur after operation as is carcinoma in other situations of the body. Provided that you can remove them during the first year or two the outlook is hopeful. I know a man working in this town now whose caecum I removed for carcinoma on February 7th, 1911, nearly ten years ago. He is well and strong and informs me that he

can carry 2 cwt. At the time of his operation he was only 28 years of age. Professor Leith, who examined a section of the growth, reported it to be "a cubical-celled carcinoma with a few columnar cells." I hope particular notice will be taken of this man's age, because I know that cases are overlooked because they are "too young to have carcinoma."

Then there is the question of haemorrhage. Many of these malignant cases do not show this symptom, yet it is present in many innocent conditions. There may be occult blood in the faeces, and so there may be in innocent conditions. Ballooning of the rectum is another condition which may be present in either malignant or innocent affections. These are links in the chain of evidence, but they are not strong enough to carry conviction.

The treatment I advocate for these cases is to operate early and freely. If there is a chance to perform a radical operation for the complete removal of the growth, by all means do so. It may not be wise to do it all at one sitting. This must depend upon the case. Take, for instance, Case IV, noted below. He was sodden with toxins, and would not have stood any lengthy operation. The obvious need was to relieve his obstruction, to free him of the poisonous matter he was absorbing. The next day I was able to perform a short-circuiting operation. Had the patient been in a good condition I should have excised the growth in the first instance.

The excision should be a free one. At least 4 in. of healthy bowel on each side of the growth, together with the mesentery and lymphatic glands, should be removed. There is some difference of opinion as to the best method to be adopted after excising the growth. Some surgeons close the ends and then perform a lateral anastomosis. I prefer an end-to-end junction. It is true that the calibres of the cut portions of bowel may be different, but that difficulty can easily be surmounted by careful suturing. The end-to-end junction is the nearest approach to Nature's arrangement, and this, I consider, should always be our aim. I prefer simple suture to any mechanical appliances, and I use linen thread, which is always reliable in my hands.

Between September 28th and October 16th last I operated upon five cases of carcinoma of the large intestine, two of them on one afternoon. When I say the large intestine I do not include the rectum. The disease is not common, and it is therefore remarkable that these five cases should have presented themselves to me within eighteen days. The following are brief histories of each of these patients:

CASE I.

W. O., a male, aged 54, had suffered from pain in the right side of his abdomen for twelve months. The pain was more acute at times, but the patient could not associate this with anything which might account for it. He had lost flesh, and was anaemic. An examination of the abdomen revealed a tense globular swelling, about three inches in diameter, in the right hypochondriac region. It was dull on percussion, and appeared to be attached to the liver. I could not separate it from the liver. There was a right inguinal hernia, which was easily reducible. It was thought that the swelling might be a distended gall bladder, and an exploratory operation was advised. On September 23th, 1920, under chloroform and ether, a vertical incision was made through the right rectus. The appendix was found to be thickened and inflamed, and was removed. A mass of hard carcinomatous growth was found in the hepatic flexure of the colon. It was delivered with difficulty and excised, with about four inches of the ascending colon and four of the transverse colon on either side. An end-to-end junction was made by simple suture with linen thread. Enlarged glands were removed with the mesentery of the colon. The patient made an uninterrupted recovery, and was discharged on October 23rd. His bowels act regularly, and he has no pain.

CASE II.

E. T., a female, aged 45, had suffered from pain in the right hypochondriac region for more than a year. The pain was worse at times, and went through to her back. She thought she had gall stones. On examination of the abdomen there was tenderness and rigidity in the right iliac region. The patient would not allow a full examination. It was thought she might have chronic appendicitis. On September 28th, 1920, under chloroform and ether, I could feel a hard, irregular mass in the right iliac region, which I thought was a carcinoma of the caecum. A vertical incision was made through the right rectus. The carcinoma of the caecum was delivered and excised, together with the enlarged glands in the mesentery, 4 in. of ileum, and 4 in. of ascending colon. End-to-end junction was made with linen thread. I show you the specimen removed. You will notice that the growth is confined to the caecum; the appendix was not affected. The patient made an uninterrupted recovery, and was discharged on November 1st. Her bowels act regularly, and she has no pain.

* Read before the Kidderminster Medical Society on December 2nd, 1920.

selected and the operation of nerve-freeing performed, a cure can be obtained in practically every instance.

The term "sciatica" is often used to cover pain in the sciatic nerve arising from very different causes, so that, in the first instance, it is necessary to be particular regarding the diagnosis. A considerable number of diseases may cause referred pain in the sciatic nerve, such as hip-joint affections, tumours or inflammatory conditions in the pelvis, exostosis, and nervous conditions both organic and functional. It is therefore essential to exclude all such causes of sciatic pain by a careful examination before one assumes one is dealing with a lesion of the nerve itself. The term "sciatica" should be confined to pain arising from inflammation or the effects of inflammation of the sciatic nerve.

It is only in chronic cases that have failed to recover under medical treatment that there is any question of surgical interference. Further, not all of those chronic cases are suitable for operation, so that it is necessary to differentiate them carefully by the symptoms to which they give rise. I have roughly classified them into three groups:

1. Cases in which the patient is quite free from pain while at rest but begins to have pain on exercise or on assuming some special position.
2. Cases in which there is a certain amount of pain while at rest, but where it becomes really intense on exercise or on the assumption of a particular position.
3. Cases in which the pain is of an indefinite character, present at rest off and on, and sometimes improving to a certain extent on exercise.

In the first type the pathology of the condition seems quite clear. The inflammation of the nerve has subsided, but adhesions have been left round the nerve as a result of the inflammation. These vary from fine adhesions to definite bands of fibrous tissue. Their mode of action seems clear, as it is only on movement that they drag on the nerve and set up pain. This type is pre-eminently the one suited for surgical treatment, and in cases of this nature one can be certain of a rapid and perfect recovery by operation.

In the second type one has the same condition of adhesions round the nerve, but, in addition, one presumes there is a varying amount of inflammation of the nerve itself still present. In some instances it is possible this may be kept up by the pull of the adhesions, especially where the patient has been making great efforts to go about. The majority of cases of this nature can also be cured by operation. In this class of case the pain sometimes takes longer to disappear completely.

In the third type the pathology is not so clear, but it would seem likely that here one has a neuritis without the presence of adhesions round the nerve. In the only case of this kind where I have operated no adhesions were found. This type appears to be unsuitable for surgical treatment.

Treatment.

The surgical treatment of sciatica was first placed on a satisfactory basis by Crawford Renton,¹ who in 1897 published an account of his operation and of the cases where it was indicated. The operation is extremely simple, and consists essentially in the freeing of the sciatic nerve from adhesions. This is done by exposing the nerve below the gluteus maximus by a four to five inch longitudinal incision, hooking it up, and then carefully removing all adhesions from the sacro sciatic notch to about the middle of the thigh. The adhesions may be fine and readily separated by the finger, or they may consist of strong bands that have to be divided. All tags and loose ends of adhesions should be dissected away. The branches to the hamstrings which come off just below the lower border of the gluteus maximus should be preserved. The nerve is then dropped back into the wound and the skin sutured. No splint is applied, but the patient is kept in bed for ten days and then allowed up.

In performing this operation one does to a certain extent pull on the nerve, but the essential feature is the removal of the adhesions. It is quite easy to demonstrate that no reasonable amount of nerve stretching will separate all the adhesions. Further, cases have been cured by this operation which had previously had nerve stretching performed without benefit. As a general rule patients are free from pain as soon as they get up, but sometimes a few weeks elapse before the pain completely disappears. The

results of this simple operation have been most satisfactory, and patients who had been more or less confined to bed for periods of six months to two years have been able to take up active occupations in a short time.

It is not possible to give records of a very large series of cases, as the operation is only indicated in a limited number of patients. Crawford Renton² has recorded thirty-two cases of operation extending over a period of thirteen years, and all of these were cured or rendered well enough to return to active life. I personally have operated on ten cases; six of these were of Type I, and all of them recovered completely; three were of Type II, and of these two made a complete recovery, but the third, although greatly improved and able to return to active work, still complained of some pain and numbness of his foot a year later. One case was of Type III; no adhesions were found, and no benefit followed the operation.

Illustrative Cases.

Type I.—I. R., a woman aged 33, a patient of Dr. MacLennan, Govan. She had been almost entirely confined to bed for nine months with a left-sided sciatica. Under medical treatment the acute pain had passed off and she was now quite comfortable when lying in bed. On attempting to walk the pain came on severely, and she particularly complained of being unable to sit for more than a few minutes without the pain becoming so severe that she had to lie down. There was practically no tenderness on pressure over the nerve, but stretching it was painful. There was some atrophy of the thigh and the Achilles reflex was diminished. At operation definite adhesions were found round the sciatic nerve, and these were freed. A fortnight afterwards she could walk and sit without pain, and five months later she remained perfectly well.

Type II.—W. M., a sailor aged 29. He had been completely incapacitated with pain in his right sciatic nerve for six months. He complained of a certain amount of pain even when resting, but especially of inability to walk any distance without the pain becoming so severe that he had to stop. There was some tenderness over the nerve, and it was painful on stretching. There was some atrophy of the thigh and the Achilles jerk could not be elicited. His sciatic nerve was freed from adhesions and a few weeks later he was quite comfortable and able to walk without pain. When seen nine months later he was still perfectly well.

R. D., a man aged 53, a patient of Dr. Gibson Graham, had had pain in his left sciatic nerve for eighteen months. In spite of medical and electrical treatment it did not improve. He complained of pain and numbness in his leg and foot even when at rest. Exercise greatly increased the pain, and he could only walk a short distance. There was tenderness over the nerve and pain on stretching it. There was atrophy of his thigh and leg muscles, and the Achilles reflex was gone. The sciatic nerve was exposed, and a considerable number of adhesions separated. A month after operation he could walk much better, although he still complained of some pain. He improved steadily, and was able to return to active work three months later. At the present time—a year after operation—he is doing active work, but states that he still has some pain and numbness of his foot at times. His Achilles jerk is still absent.

Type III.—J. S., a man aged 50. He gave a history of sciatic pain on the left side of two years' duration, which had persisted in spite of medical treatment. He complained of irregular attacks of pain often coming on while at rest. The pain was sometimes severe in the morning, and improved when he had been going about for a little. There was tenderness over the nerve and pain on stretching it, as well as considerable atrophy of the thigh and gluteal muscles. The Achilles reflex was absent. At operation practically no adhesions were found, and no improvement followed.

Conclusions.

1. Cases of sciatica which are free from pain while at rest but in which the pain commences on exercise can be cured by operation.
2. Cases in which there is a certain amount of pain while at rest but where it becomes much more severe on exercise can usually be cured, or at any rate greatly improved, by operation.
3. The operation consists in the freeing of the sciatic nerve from adhesions and not merely in nerve stretching.

In a paper read at a meeting of the Society of Public Analysts, on April 6th, Dr. J. C. Thresh stated that the conflicting views held with reference to the action of water on lead had induced him to reinvestigate the matter. He found that if water were free from dissolved oxygen it had no action on lead, but that if free oxygen were present action began instantly and continued until all the oxygen was used up.

SURVIVAL AFTER OPERATION FOR ANNULAR MALIGNANT DISEASE OF THE LARGE BOWEL.

BY

JOHN D. MALCOLM, F.R.C.S. EDIN.,

CONSULTING SURGEON, SAMARITAN FREE HOSPITAL, LONDON.

THE cases here recorded encourage a resort to surgical treatment:

CASE I.—Lived Seven and a Half Years with a Fistula.

A man, aged 78, of powerful physique, seen with Dr. Andrew Elliot and Dr. R. P. Cockburn, had suffered for many months from an increasing intestinal obstruction located in the transverse colon. Operative treatment was recommended, but no guarantee could be given that the formation of a fistula would be avoidable, and nothing was done until a bout of vomiting with abdominal distension seemed likely to terminate in death. On March 21st, 1920, the patient opened the abdomen, and felt an annular constriction of the transverse colon near the splenic flexure. A lateral fistula was made in the presenting portion of the enormously dilated large bowel, which was afterwards identified as ascending colon. Further treatment was considered unwise at that time.

The patient bore the operation well, and recovered satisfactorily with hardly any vascular or other disturbance. From the first he was subject to attacks due to accumulations in the transverse colon which were accompanied by pain, discomfort and high temperature, until an offensive discharge took place through the fistula. Dr. Cockburn kindly informs me that after about four years these attacks began to be associated with escapes of irritating matter, mainly mucus, through the anus, by which small quantities of faeces were passed at intervals to the last. Between the attacks the patient was wonderfully well and able to go out until the end of October, 1920, about which time secondary nodules were discovered, first in the hepatic flexure, and later throughout the abdomen. The patient died on January 6th, 1921, more than seven and a half years after the operation.

It was proposed to short circuit this patient's ileum into his sigmoid flexure and, if possible, to remove the strictured bowel when he recovered from the fistula formation. Elderly people of strong physique, especially those with powerful hearts, bear operations well, and this patient appeared to be capable of undergoing successfully the necessary interference, but he refused further surgical treatment. His record shows that an annular malignant stricture of the colon may long remain local, and clearly the full advantages which surgery may give were not obtained in this case. After a successful second operation the man might have been quite well now, but such results cannot be secured without risk.

CASE II.—Apparently well 23 Months after Hysterectomy and Proctectomy.

A woman, aged 44, married five years but never pregnant, was sent to the Samaritan Free Hospital under my care by Dr. Reginald Clark. An abdominal tumour apparently existed before her marriage and greatly increased in size in the last few months, during which the patient rapidly lost weight until emaciation, anaemia, and feebleness were extreme. There was no intra-abdominal pain or tenderness, but vaginismus prevented a satisfactory examination. On March 28th, 1919, under anaesthesia, an oval tumour was defined rising to the ribs from low in the pelvis, and so fixed by its size that its origin could not be ascertained. A uterine sound was not used. In the rectum, three inches from the anus, an ulcerating growth completely encircled the bowel, but caused no constriction and little discharge. A piece of this, removed for examination, showed the structure of a carcinoma. The rectum moved freely behind the large tumour, which was thought to be ovarian and probably malignant.

The proper treatment was to operate if the rectal condition had not existed, and the rectal growth, apart from the other, appeared to be removable. The propriety of interference with these doubtful conditions had to be the more seriously considered because of the feeble condition of the patient. She, however, expressed a very strong desire to take any risk on the chance of getting relief from her discomfort and sense of weakness. It was therefore decided to explore the abdomen, the patient being told that if the large tumour could be removed it would be wise to treat the rectum by a second operation later.

First Operation.—On April 1st, 1919, an incision exposed a large fibromyomatous uterus, with its base deeply buried in very oedematous broad ligaments. The oedema seemed to be due to pressure. The whole uterus and the left ovary and tube were removed. Before closing the abdomen the rectal growth was examined and no sign of its extension beyond the bowel was found. The liver also seemed normal. The patient, although somewhat collapsed for a few days, recovered well.

The highest temperature was 100.4° F., the highest pulse 110. The tumour contained many cysts full of degenerating fluid, but no malignant growth was found in it.

Second Operation.—Two weeks later, on May 6th, 1919, the patient's condition being much improved, the abdomen was again opened. After freely separating the rectum from its connexions, an attempt was made to bring the upper end of the divided sigmoid flexure down to be joined to the bowel close to the anus. This was impossible without either undue tension or division of a large vessel which nourished the greater part of the sigmoid. The attempt to make an end to end anastomosis had therefore to be abandoned, and the divided upper end of the sigmoid flexure was brought out on the groin as a fistula. After removal of the rectum and the anal mucous membrane down to the external sphincter, the pelvic floor was closed with difficulty, because of the absence of the uterus. The right ovary and tube helped to fill the gap, but a very large cavity remained and was packed with gauze round a drainage tube introduced through the anal wound. The abdominal incision was then closed.

After History.—The patient was much more feeble after this operation than after the first, and a great deal of discharge escaped from the anal opening, but it gradually ceased. The temperature rose to 103° F. on the third day, the pulse to 120. Both then fell until the fourteenth day, after which they were normal and the patient went home, almost healed, fifty-one days after the second operation. A month later (July, 1919) she weighed 6 st. 7 lb. On December 21st, 1920, she weighed 11 st. 13 lb. and had every appearance of robust health. The pelvic parts were all soft and the fistula acted well.

Dr. W. H. Baker tells me that her condition is still quite satisfactory. Of course, within two years of an operation for cancer a patient's future must be considered uncertain, but the first of these histories shows that a bowel cancer may be localized for a long time. In the second it seemed certain that a wide removal of the disease had been effected, and in any case the result to the patient has already amply justified the operative interference.

THE HOSPITAL TREATMENT OF FRACTURES:

A SUGGESTION FOR CENTRALIZATION.

BY

ROBERT OLLERENSHAW, F.R.C.S. ENG.,

HONORARY SURGEON IN CHARGE OF ORTHOPAEDIC DEPARTMENT,
SALFORD ROYAL HOSPITAL.

IN 1903, in an address before the Medical Society of London, on the "After-effects of injuries," the late Mr. Clinton Dent made some statements as to the results of fractures amongst members of the Metropolitan Police Force. These men, who, before their injuries, were physically almost perfect, were treated in various metropolitan hospitals, and Mr. Dent, as consulting surgeon to the police, had to pass judgement on the final result and estimate the functional recovery. He stated that the results were much less favourable than was generally imagined, and he made a strong plea for the better care of fractures. He particularly pleaded that early fixation in plaster-of-Paris for a period judged to be long enough to ensure sound union should not be adopted as a routine line of treatment. He found that, after fractures of the lower limb, 30 per cent. failed permanently to get full functional recovery, and very few had fully recovered in six months from the time of the injury. It is probable that this figure represents fairly accurately the state of affairs to day.

In 1903, and since that time, the fractures admitted to most of our general hospitals went to the wards which happened to be receiving urgent cases, quite regardless of whether the surgeon in charge of those wards had any special interest in the treatment of fractures or not. In most busy general surgical units a serious fracture is not looked upon as a welcome visitor. It is a case which is certain to hold up a bed for a long period, and which will interfere with the admission of more interesting general surgical cases. In the present state of busy wards and long waiting lists, it becomes almost the first business, therefore, to get the fractures disposed of as quickly as possible. Two chief methods offer themselves:—First, transfer to a Poor Law hospital with its multitudinous beds, or, secondly, discharge to the patient's home after fixation on some form of splint which cannot be interfered with, such as plaster-of-Paris.

When one remembers that an inferior result after a fracture of the lower extremity may permanently reduce

the capacity of a young and strong workman from full hard work to light work, or "no ladder work," or some seriously limited occupation, it is obvious that the very best effort should be put forward to procure the most perfect functional result which is possible. In order to ensure this result it is very desirable that the same surgeon should supervise the case from start to finish. He should be entirely responsible for the case whilst in the wards; he should supervise its manipulation and splinting, its early massage, and, on discharge, its progress through the out-patient department and physio-therapeutic department. He should control the entire physio-therapeutic treatment.

Many of our general hospitals now have orthopaedic departments. In these hospitals the fractures naturally go to the wards associated with this department. The work of an orthopaedic surgeon differs in one very important respect from that of the general surgeon in that the former frequently has to undertake much more prolonged after-treatment of his patients. The operative measures employed, though essential and highly important, may be a mere incident in the course of the whole treatment. Weeks or months of patient physio-therapeutic measures, accompanied by the constant supervision and adjustment of mechanical appliances, may be required in order that the value of the operation may not be lost.

Similarly in the case of fractures, supervision of the whole of the after-treatment is of the very highest importance. In hospitals which have no special department for orthopaedics, a member of the surgical staff should be selected to take charge of the fractures. He should naturally be one with some leaning towards orthopaedics, who would be able to devote the necessary time to the work, which would, in this case, be in addition to his general surgical duties. He should be allotted a sufficient number of additional beds for fractures. This number will be arrived at from a survey of the in-patient records. It will be found to work out, in the average general hospital, at 6 per cent. of the total surgical beds. In areas which are almost entirely industrial this figure may be a little higher.

Under a system of centralization such as this the surgeon in charge becomes more expert in his methods, the house-surgeon of the unit receives real thorough instruction and practice in his art, the nursing staff becomes extremely skilled in the handling and adjustment of splints and the nursing of patients in fracture apparatus, and the general wards are relieved of cases which are somewhat alien to them. At Salford Royal Hospital, where an orthopaedic department was opened in 1918, the system has worked extremely well and with the greatest advantage to all concerned.

NOTES ON A GIANT.

BY

WILLIAM ROBINSON, M.S., F.R.C.S.ENG.,
SENIOR SURGEON, ROYAL INFIRMARY, SUNDERLAND.

SINCE Ord described "the cretinoid state in adult women," and surgeons showed that complete removal of the thyroid gland brought about myxoedema, the functions of the ductless glands have been constantly investigated. Before that time we knew only that the complete removal of the sexual glands in man, sheep, cattle, horses, and other animals not only prevented reproduction, but made them docile and fat, thus affecting character as well as growth. Afterwards Marie, in 1885, showed that growths and hypertrophy of the pituitary gland caused acromegaly, and since then it has been slowly established by surgeons that the anterior lobe of the pituitary gland presides over the growth of the body. This discovery led Professor D. J. Cunningham to slip his finger through the foramen magnum of the skull of Hunter's costly giant, Byrne, in the Hunterian Museum, and to discover its expanded and shallow pituitary fossa; and Professor Arthur Keith later to cut a window in the cranial vault, and so render the enlarged fossa visible to the eye. (John Hunter is said to have paid the watchers of Byrne's corpse £500 to allow the body to be kidnapped.)

Recently E. Uhlenroth, of the Rockefeller Institute, has produced experimental giantism—that is, growth beyond the normal size of the species—in the salamanders by feeding them on the anterior lobe of the pituitary gland. The function of the posterior lobe is unknown, and when given as food not only was growth not stimulated, but actually retarded. It is the intermediate part of the gland that supplies the extracris which excite unstriated muscle, raise blood pressure, and produce diuresis.

The effect produced depends on the developmental stage of the salamander; no effect is produced on the larva. At the stage when growth ceases or is normally much lessened, cell proliferation can be enforced by the specific substance in the anterior lobe of the hypophysis.

The giant "F." consulted me six or seven years ago. He was then 20 years of age, his height was 7 ft. 8 in., he

was still growing, and he weighed over 22 st. Although so tall he was fairly proportionate, except that his hands, feet, skull, and lower jaw were perhaps unduly large. His hands were long and shapely, and differed from the short, broad, spade-like hands and sausage-like fingers of the acromegalic, the age of onset accounting for the difference. When the disease is congenital or begins during the growing period of youth, gigantism results; if after 25, acromegaly is produced. When "F." stretched out his arm at right angles to his body, the writer (height 5 ft. 11 in.) could walk comfortably under it. "F." knew that giants died young, and his ambition was to live long enough to outgrow the Chinese giant, who, he said, was 8 ft. 4 in. in height. So far he had had no serious illness. His sexual organs were normal. He had no pressure symptoms in his brain, and these were not to be expected, as an x-ray photograph showed a pituitary fossa quite normal in shape. All his bones were overgrown in breadth as well as in length, and the soft structures of the body were similarly affected; nor is this surprising as far as the muscles are concerned, when it is remembered that biologically bone is secondary to muscle and not muscle to bone. Three excellent skiagrams were taken for me by Dr. A. C. Norman, and I append a description of each:

Giant "F." with a man of ordinary height standing beside him.

1. *Skull*.—The sella turcica—like a capital U in shape—admits two-thirds of a shilling in the antero-posterior plane, whilst that of an ordinary skull will admit only a threepenny piece. The greatest length from chin to occiput is 12½ in. From forehead to occiput measures 9½ in. The thickness of the skull in many places measures ½ in., and at the external occipital protuberance ¾ in. The air-containing sinuses are very large, especially the frontal, which measures ¾ in. antero-posteriorly. The lower jaw is huge.

2. *Forearm and Wrist*.—The inferior extremities of the radius and ulna are not the age of 20. His limbs are, therefore, still growing.

3. *Hand and Wrist*.—From the wrist-joint to the tip of the middle finger measures 11½ in. The greatest breadth of the hand at rest at the head of the first metacarpal bone measures 6 in. The parts of the hand are proportionate. His thumbnail is 1½ in., and that of his middle finger 1 in. in length. Ossification: (a) The heads of the inner four metacarpals are joined to their respective shafts, and so is the base of the thumb metacarpal to its shaft, as they all should be at the age of 20. (b) The bases of the first and second rows of the phalanges are not yet united to their shafts as they should be at 20; but those of

the third row are as they should be at his age. The fingers and the thumb are evidently still growing.

"F." had an average intelligence and was not ungainly, though most giants are said to have been dull, feeble, ungainly, and short-lived. Magrath, 7 ft. 5 in., died in 1760 at the age of 24. Chang, the Chinese giant, was an exception, and so was the Russian, Machnow, who at 23 measured 9 ft. 3 in., and was well proportioned. He was, perhaps, the biggest of modern giants. Byrno measured 8 ft. 4 in. after his death, which took place at 22. Og, the king of Basan, was handsome (Josephus), and his non bedstead was 13 ft. 6 in. by 6 ft. Goliath of Gath was 9 ft. 6 in., or according to Josephus 8 ft. 9 in., and his hand was big, for "the staff of his spear was like a weaver's beam." Classical evidence of giants measuring 46 and even 60 cubits is mythical and untrustworthy. The Scriptural evidence of races of giants does not amount to much. The two Hebrew words translated "giants" in the Authorized Version and "nephelim" and "mighty men" in the Revised Version did not apparently apply to giants in our sense of the word.

Even the celebrated naturalists Cuvier and Buffon fell into the popular delusion of there being "giants in those days" by figuring the fossil bones of elephants, rhinoceroses, mastodons, etc., as remains of human giants. Nevertheless human skeletons of extraordinary size have been found in the caves in the "Red Rocks" of Montone, where they measured 6 ft. 6 in. in length, and showed evidences of powerful muscular development; and in Scotland, where five such skeletons were found together at Logie Pert, Forfarshire. We must therefore admit that giantism may be racial as well as the result of disease. The tallest men now living in the British Isles are said to be the villagers of Balmaclellan, in Galloway, whose average height is 5 ft. 10.46 in. (Dr. Beddoe). The average height of the Tehuelches of Patagonia is only 5 ft. 10 in.

INVOLVEMENT OF THE ORBIT IN DISEASE OF THE NASAL ACCESSORY SINUSES.

BY

ROBERT E. WRIGHT, M.B., MAJOR I.M.S.,

AGING SUPERINTENDENT, GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS.

It is not so very long ago that most cases of orbital cellulitis applying for relief at large ophthalmic clinics were regarded as of unknown origin. Even now the most diligent inquiry often fails to explain the mode of onset in certain cases. It should, however, always be remembered that until the ophthalmic surgeon can prove the accessory sinuses of the nose healthy, he is not justified in looking for a more obscure seat of origin elsewhere. The intimate relation between the orbit and the nasal accessory sinuses is familiar to all. To those who dip slightly deeper, and familiarize themselves with illustrations of the work of Onodi or of others who have for a considerable time drawn attention to this important matter, it must appear strange that extension from infected sinuses to the cellular tissues of the orbit is not more frequent. Probably mild degrees of periostitis are much more frequent and much more serious than is commonly thought. If ophthalmologists have been to blame in the past for accepting orbital cellulitis as a clinical entity, this cannot be said of those rhinologists who of recent years have devoted so much time and labour to the nasal accessory sinuses. Owing chiefly to their researches, it is now a recognized fact that cellulitis of the orbit is nearly always due to accessory sinus disease.

In a large out-patient department like that of the Government Ophthalmic Hospital, Madras, a considerable number of such cases report for treatment. More than half of the cases are children, in whom it is often very difficult to locate the sinus trouble; fortunately in adults it is simpler. In either case the nose should be carefully examined by the usual inspection methods; transillumination should be performed, and, if possible, a good x-ray photograph obtained. In children the sinus disease is more often of a primary acute nature, whilst in adults it is more frequent to meet with an exacerbation of a chronic

condition. It is remarkable how often orbital cellulitis clears up by mere drainage, but it is to be remembered that a certain number of patients come back later with optic atrophy. This note is intended, however, to record the comparative frequency with which one of these sinuses was responsible for cases of orbital trouble reporting to this hospital during the last quarter of 1920. Six cases in all were met with. This is greatly in excess of the average rate at which orbital complications are met with in frontal sinus disease in Madras. The case notes are as follows:

CASE I.

R. P., Hindu male, aged 27, presented himself on September 19th, 1920, complaining of swelling of the left upper lid of three months' duration. His sight was not affected, but he had been troubled with nasal discharge. There was a small, rounded, firm swelling below the middle of the superior orbital rim and marked ptosis. While examining the cyst-like tumour the patient volunteered the information that he could empty it, and proceeded to do so by squeezing firmly upon it and evacuating the contents (about a drachm of mucus pus) upon the floor. There was tenderness on pressure against the floor of the sinus. The left nasal fossa showed hyperæmia, swelling of the middle turbinate, with polypi and pus in the middle meatus. A frontal sinus probe could not be passed; transillumination was negative. An x-ray photograph showed small symmetrical frontal air sinuses without marked septa. A certain amount of fogging on the left was the only indication of disease. There was no history of syphilis, and the Wassermann reaction was negative. Both fundi were normal.

Drainage by the intranasal route was adopted. The anterior part of the middle turbinate was removed with scissors and snare, and the ethmoidal cells broken down. A large escape of pus occurred on opening the agger cells. As the ostium of the frontal sinus was cleared and enlarged, pus flowed freely into the middle meatus. Drainage was established by enlarging the fronto-nasal canal and ostium. Irrigation was subsequently carried out for a short time. The patient left hospital on October 28th, 1920, free from swelling, ptosis or tenderness, and without discharge from the frontal sinus.

CASE II.

R., Hindu male, aged 30, came to hospital on September 20th, 1920, complaining of dull vision on the right side and discharge from the upper lid. R. eye, V. = 1. at 2½ metres due to old leucoma; fundus normal. L. eye normal. The lid disease commenced three and a half years ago with unilateral head ache and offensive nasal discharge. He had interrupted attacks of pain during this time. During one of these, five months ago, a swelling appeared below the brow. He had it opened, and as it would not heal he came to hospital. The sinus led to necrotic bone in the roof of the orbit. Examination of the nose showed polypi, and pus in the middle meatus. A frontal sinus cannula could be passed on the left but not on the right. Transillumination was negative. An x-ray photograph showed very extensive frontal sinuses on either side, divided into loculi by well-marked septa. There were large orbito-ethmoidal cells. The Wassermann reaction was negative, and there was no clinical evidence of syphilis.

The external route was chosen for operation. A Kilian incision was made and the frontal sinus opened at its inner end. The mesial septum between the sinuses was eroded, and a probe could be freely passed through to the temporal region on the left. The left ostium communicated freely with the nose, that on the right was effectively blocked. There was erosion of the floor of the right sinus and subperiosteal pus over the os planum and lacrimal bone. The orbito-ethmoidal cell was opened and both it and the frontal sinus were put in free communication with the middle meatus. The necrotic inner wall of the orbit was removed. The wound was partially closed, drainage being established from its inner end through the free opening into the nasal fossa. For some time gauze wicks were renewed daily, then irrigation with a frontal sinus cannula was carried out. Clear fluid returned from both sinuses after about five weeks, and he was discharged almost well on November 11th, 1920. In this case the Kilian type of operation was adopted, and the trochlea was saved by leaving a bridge. The lacrimal sac had to be removed. The important points in such cases are to establish good intranasal drainage without doing muscular damage, and avoid deformity due to subsequent contraction of scar tissue.

CASE III.

K. M., Hindu male, aged 40, reported on October 16th, 1920, complaining of swelling and pain of the left eye. R. eye, V. = 6/18, fundi normal. He gave an unreliable history of the swelling starting one and a half months before. He had no nasal discharge. He denied syphilis, but his wife had a suspicious record. The Wassermann reaction was positive. His right eye was much proptosed, there was extensive swelling of the lid, brow, and root of the nose. There was a pulsating swelling about the size of half an eyeball an inch above the inner end of the right brow. On firm pressure this disappeared and a circular loss of bone could be felt. This gave the patient acute pain, and cat nasal fossa was so made out, ever adrenaline. There

The
could
be
posed

bone could be felt high up with a soft blunt probe. An x-ray photograph showed large frontal sinuses divided into loculi with a fairly sharp outline on either side. There was a definite general haze round the glabella, but no indication of an opening in the anterior wall of the left sinus. The antra were clear on transillumination.

On October 18th, 1920, the pulsating swelling was opened by a vertical incision and a large quantity of glairy muco-pus escaped. Through this opening the sinuses were explored and were found to reach 2 in. above the orbital rim, and to the external angular processes. The nasal fossa was easily entered with a blunt probe on the right but not on the left. A Killian incision was made. This disclosed a complete absence of the roof of the orbit and extensive caries with the dura exposed above. The nasal fossa was now easily entered on the left. The carious ethmoidal cells were curetted away and a large drainage orifice made into the nose. Gauze wicks were led through from the upper incision and the inner extremity of the lower incision to the nose, and from the body of the sinus to the outer angle of the wound. In spite of careful drainage and vigorous antisyphilitic treatment it became obvious after some time that it was essential to remove the anterior wall of the left sinus and let the skin fall in. This was done on January 7th, 1921, good drainage was established right and left, and after careful curetting the wound was lightly packed. The patient made an uninterrupted recovery. The deformity was, of course, considerable.

CASE IV.

A. C., Anglo-Indian, aged 51, was admitted on October 22nd, 1920, with proptosis of the right eye, with swelling and oedema of the lid and brow, and acute pain. There was no impairment of vision. The first symptoms he noticed were bulging of the eye and double vision. A month previous to this he got a knock on the brow, and a week before exposed himself by sitting up shooting. Shortly after this severe pain started. When seen at hospital he presented a typical picture of orbital cellulitis. An incision was made in the superior fornix and pus evacuated, but this did not relieve the condition, and a fluctuating swelling appeared over the outer third of the eyebrow. Nasal examination revealed oedema of the middle turbinate and pus coming from the frontal sinus. No x-ray photograph was obtained. On November 15th, 1920, the frontal sinus was opened by the intranasal route. This did not relieve the condition, and a week later the external operation was done. There was caries of the orbital rim and a large pocket of pus under the periosteum of the orbital roof, which was perforated and opened into the frontal sinus. The latter was small and communicated with the superior meatus with a very angular fronto-nasal duct. Free drainage was established into the middle meatus, and gauze drains led through. About a month later a large sequestrum was removed from the outer part of the orbital rim. The patient frequently complained of severe neuralgic pain. In spite of a negative history of syphilis and a negative Wassermann reaction he was put on mercury and iodides. He improved steadily, but still complained of supraorbital pain. He was discharged at his own request, without diplopia, and with diminished proptosis, but there was considerable interference with the movement of the upper lid due to adhesions to the periosteum at the orbital rim.

CASE V.

This was a case of very extensive ulceration of the orbit and frontal sinuses, due to gummatous disease, superimposed upon which was myiasis. This case has already been fully recorded, as it was of interest also from an entomological point of view, the adult flies having been hatched out from the maggots.¹

CASE VI.

M. R., European, aged 42, was admitted on December 31st, 1920, complaining of acute supraorbital pain on the left side, which had prevented him from sleeping for some time. He had very slight swelling of the lid and thickening of the supra-orbital nerve. There was pain on pressure against the orbital rim and the nerve was excessively tender. The vision was 6/5 for both eyes and the fundi were normal. There was a negative history of syphilis, no clinical signs, but a positive Wassermann reaction. An x-ray photograph was not obtained. Transillumination was negative. He gave a history of a very severe fall from a motor bicycle five months before, with temporary unconsciousness and bleeding from the ear. The exact location of the latter was somewhat uncertain, and he had a perfectly normal drum. There was no history of influenza or acute catarrh. The nasal fossa looked healthy, but on passing a cannula into the fronto-nasal duct a small quantity of muco-pus was evacuated. He was given an injection of novocain, followed by alcohol, into the supra-orbital nerve, which relieved his pain. On December 31st, 1920, the anterior end of the middle turbinate was removed with scissors and snare and the ostium of the frontal sinus enlarged. The anterior ethmoidal cells were also broken down. He developed a third nerve paralysis three days after operation. He was put on injections of mercuric cream and novarsenobillon on alternate weeks and rapidly got better. On January 21st, 1921, the paralysis had almost gone and there was no diplopia. He had no pain and his nasal fossa and sinus were apparently healthy.

THE ISOLATION OF DIPHTHERIA BACILLI.

BY

DENYS R. WOOD, F.I.C.,

PUBLIC ANALYST AND BACTERIOLOGIST, SOMERSET COUNTY COUNCIL.

It is sometimes necessary to obtain the diphtheria bacillus in pure culture in order to test its pathogenicity, as, for instance, when found in swabs taken from lesions other than the throat and nose, such as the ear, the eye, and sores on other parts of the body, and occasionally from the throat and nose also in the case of very persistent carriers.

A useful medium for this purpose is described in Browning's *Applied Bacteriology* as follows:

Sheep serum, sterilized by heating on several occasions for one hour at 57° C. ... 5 c.cm.
1 per cent. telluric acid in distilled water ... 0.9 c.cm.
Peptone water agar (roughly neutral to litmus) to ... 100 c.cm.
The serum and telluric acid solution are added to the melted agar at 50° to 55° C. before pouring into Petri dishes.

In my experience sheep serum, when the blood is obtained from the abattoir, is seldom sterile when heated at 57° C. for one hour on seven or eight consecutive days, and the ether and chloroform methods of sterilization are equally unreliable, in fact, the only reliable method appears to be filtration through a Chamberland filter. It is therefore a great advantage to be able to dispense with this constituent.

Diphtheria bacilli grow exceedingly well on Gordon and Hine's legumin tryptagar,¹ and when this medium is used no sterile serum is necessary. The addition of 0.3 c.cm. of sterile 1 per cent. telluric acid to 10 c.cm. of this agar gives a very satisfactory medium. Plates of this medium are poured, and when set brushed with a dilute emulsion of the growth containing the diphtheria bacilli and incubated at 37° C. for forty-eight hours, by which time the characteristic appearance of the colonies of the different organisms is most distinct.

The majority of organisms other than the diphtheroids reduce the telluric acid and produce blackish colonies; this is very marked with the staphylococci. The streptococci do not reduce the telluric acid, their colonies are characteristically greyish-white, small (usually less than 1 mm. diameter), very flat and very translucent. The colonies of the diphtheroids are greyish-white, semi-translucent, slightly convex, about 1 mm. in diameter, with a slightly darkened central spot. By the use of this medium I have selected as many as five colonies of *B. diphtheriae* in succession from a plate containing numerous colonies of other organisms.

The morphology of the diphtheria bacillus when grown on legumin tryptagar differs from its morphology when grown on Loeffler's serum; the bacillus stains more uniformly, the characteristic beads are not evident, and club-shaped forms are common. With a little practice, however, it can readily be recognized and distinguished from Hoffmann's bacillus grown on the same medium. It is unfortunately not possible to distinguish between the colonies of Hoffmann's bacillus and those of true diphtheria bacilli. Douglas's trypsin broth² with the addition of pea-flour extract and 0.5 per cent. Witte's peptone (to help toxin production), is very suitable for the cultivation of *B. diphtheriae* for animal inoculation. Almost invariably a good growth is obtained—an essential condition of the experiment—while with ordinary broth this is far from being the case, the growth more often being only scanty. Glucose litmus legumin trypsin broth is very suitable for the observation of acid productions from this sugar.

A SMALL Italian surgical hospital with an out-patient department has been opened at Aleppo by the National Italian Association.

THE sixteenth Congress of the German Orthopaedic Society will be held in Berlin from May 18th to 20th, when the principal subjects for discussion will be bone and joint tuberculosis and rickets.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PREVENTION OF INTESTINAL OBSTRUCTION AFTER VENTROFIXATION.

In the *Epitome of Current Medical Literature* of the JOURNAL of February 12th there occurs a paragraph (No. 216) on "Intestinal Obstruction after Ventrofixation of the Uterus," by Hastrup, from *Ugeskrift for Læger* of December 30th, 1920. After losing a patient, on whom I had operated, owing to obstruction of an intestinal loop, I have always closed the space between the retroflexed

FIG. 1.—The vertical dotted line is on the uterus, with limbs at right to show disposition of peritoneum—dissected Cecum and knots above—how the lines of suture of uterus to bladder and abdominal wall (catgut). Two or three strong silk wound sutures as fundus above a knot wall.

uterus and the bladder before fixing the uterus, in the following way: The whole of the bladder surface of the body of the uterus, from the fundus down to the line of reflexion of the bladder, is bared of its peritoneal covering by dissecting back two flaps as in the figure. At first I dissected similar flaps on the bladder, but this part was more difficult and is not necessary. The bared uterus is next united to the bladder and peritoneum above by central catgut sutures. These are of fine gut, and care must be taken not to put the bladder sutures too deep.

A continuous catgut suture next unites the dissected flaps all round from bladder reflexion on one side to the other over the fundus. The rest of the operation is done in the usual way.

I have had only one opportunity of seeing the late result, and there instead of the usual band there was a broad ligament supporting the uterus. There has been no return of prolapse, though usually no vaginal operation has been done, and several have borne children with no difficulty, and no return of the prolapse. I have no doubt others will have done the same operation, but from the abstract in the *Epitome* the method does not seem to be well known. It can, of course, be combined with operative treatment on the round ligaments, but I have not considered both necessary.

Aberdeen.

ALEXANDER DON, C.M., F.R.C.S.ED.

AMOEBIĆ DYSENTERY COMPLICATING MALIGNANT DISEASE OF THE LOWER BOWEL.

The following case is of some interest from the fact that *Entamoeba histolytica* was found microscopically four months prior to death from carcinoma of the pelvic colon.

C. L., a ship's painter, aged 41, who had never been in the tropics, was admitted to Queen Mary's Hospital for the East End on October 10th, 1920, suffering from diarrhoea with blood and mucus. He first had diarrhoea and colicky pains four months previously, but he continued work down to three weeks before admission. His physique was good, but he appeared slightly anaemic; the tongue was slightly furred; he had an upper denture, the lower teeth were good, and he had no lead line on the gums. The heart and lungs were normal. The abdomen was rather full and tympanitic, with tenderness in the left iliac fossa. The liver and spleen were not enlarged nor tender; there was no pain on micturition. Urine, specific gravity 1022, acid, and free from albumin. The stools were pale and watery, containing large jelly-like masses and shreds of blood stained tissue. Temperature 98.6, rising to 99.2 in the evening. The bacteriologist reported the presence of free amoebae of *E. histolytica* type. Plates were negative for *D. dysenteriae*. Sigmoidoscopic examination showed the mucous membrane pale, but no ulceration or inflammation of bowel within 9 in. of anus.

Emetine bismuth iodide, grains 3, was prescribed; twelve doses were taken from October 18th to October 30th; the lower bowel dition rength, daily. The two courses of emetine given in November and cterologist reported that the stools were very fluid, without blood or mucus; no amoebae or cysts were found, and there was no cellular exudate.

The diarrhoea persisted with occasional mucus and blood, and the patient was losing weight and becoming cachectic, de Morgau spots were seen on the body, the skin was atrophic, and the tongue furred. Rectal examination showed ballooning, but no growth could be felt. The abdomen, when examined on January 12th, 1921, was soft and flabby with wasted muscles; a firm nodular tumour the size of a Tangerine orange, slightly movable, but adherent to the pelvic structures, was palpable just above the pubis. The lower edge could not be reached. Laparotomy was performed by Mr. Cousins on January 14th. A large malignant mass was found in the lower abdomen involving the descending and pelvic colon, a loop of small intestine, and the base of the bladder. An anastomosis of the small gut into the transverse colon was performed and the abdomen closed. Later there was some amelioration of the symptoms, but death occurred on February 16th.

The autopsy revealed a large malignant growth encircling the bowel about ten inches from the anus, extending upwards and involving about four inches of large bowel. The primary growth showed necrotic changes, and numerous elongated shreds of growth, with which was mixed dark clotted blood. No mucus was discovered. A coil of small intestine three feet above the caecum had become invaded by growth and its lumen almost occluded. The primary growth encircling the large bowel had not caused obstruction. The growth was adherent to the bladder but did not ulcerate through. Secondary deposits were found in the mesentery of the small bowel but not in the liver. The anastomosis was soundly healed and functioning. The liver showed fatty changes and was very bile-stained. There was no jaundice.

I consider that the malignant disease was not of recent origin, and that it was present at the time he had his first symptoms, seven months before death. The amoebic dysentery was merely a complication, and probably had no bearing on the causation of the growth. However, the fact that *Entamoeba histolytica* was found four months before death made the case unusual and obscured the real diagnosis. I have to thank Dr. Troup, under whom the patient first was, and Mr. Cousins, for their kindness in allowing me to publish this case.

Honorary Physician, Queen Mary's
Hospital for the East End.

Reports of Societies.

DIGESTION OF THE OESOPHAGUS.

At a meeting on March 18th of the Royal Medico-Chirurgical Society of Glasgow a communication was made on "Digestion of the oesophagus as a cause of post-operative and other forms of haematemesis," by Mr. J. HOGARTH PRINGLE, Dr. LAURENCE T. STEWART, and Professor J. H. TRACHER. Post-operative haematemesis, they said, was a symptom of great importance to the practical surgeon, and associated with serious danger to the patient. In recorded cases various explanations were given, but digestion of the oesophagus was not mentioned. A few cases of *intra vitam* oesophagomalacia and ulcer a digestion had been recorded, and in July, 1914, Glynn demonstrated to the Pathological Society of Great Britain and Ireland sections of the oesophagus which showed ulceration and inflammatory reaction.

Prior to January, 1914, one of the authors had seen two cases of destruction of the lower part of the oesophagus which looked as if this might have commenced during life. Then a case occurred, under the care of Mr. Pringle, in which vomiting of brown material was observed after operation and about thirty-six hours before death. There was also complaint of pain behind the sternum. No cause of these symptoms except digestion of the oesophagus (which had not gone the length of perforation) could be made out, and the observation then ceased to be a pathological curiosity and became a matter of practical importance. In 1919 the authors made a communication to the *British Journal of Surgery* (vol. vi, No. 24, p. 523) on this subject in which they described a number of cases in which digestion of the oesophagus appeared to have been the cause of haematemesis or vomiting of brown or black material and in some cases the cause of death. Several of the cases in the series were not surgical but medical cases—for instance, anthrax, pneumonia, puerperal eclampsia. On clinical and morbid anatomical grounds the digestion of the oesophagus was regarded as a vital phenomenon. Sections from a number of these cases were shown to the Pathological Society at the meeting in Leeds in January,

1921, and full publication would later be made in the *Journal of Pathology and Bacteriology*.

Intra vitam digestion of the oesophagus was supposed to arise in the following manner. Vomiting of active gastric juice occurred, but the oesophagus failed to clear itself and some of the fluid remained in it, accumulating particularly just above the cardiac sphincter, in which region the injury to the tube was usually most advanced. In post-operative haematemesis the fluid ejected was usually extremely acid, and those patients who were sufficiently conscious to be able to express themselves frequently complained of the scalding effect which it had upon the throat and lips. The lesions produced before death by gastric juice which has escaped into and lain in the oesophagus were apt to be more or less obliterated by changes due to continuation of the digestion after death. In twelve of the fifteen cases which were described in 1919, and in four new ones, however, microscopic examination had revealed unmistakable signs of vital reaction, in the form of abundant leucocytic infiltration of the mucous membrane and other tissues, congestion of blood vessels, accumulation of leucocytes in the vessels, thrombosis, and inflammatory oedema. The picture was that of an acute ulceration. It was easier to recognize these changes than to assess the extent to which they might have been obscured or obliterated by continuation of digestion, or to decide the relative amounts in which that digestion was a continuation of the lesion which developed during life or a *post-mortem* change. Probably these cases had been observed, but the lesions had been put down as merely *post-mortem* digestion, from which, however, it was not now difficult to distinguish them. It was therefore clear that digestion of the oesophagus during life did occur; that it might be the cause of death; that it occurred in other than operation cases, and that it might be arrested and healing take place. Its occurrence was shown by haematemesis, and in some cases by pain behind the sternum. It was therefore open to diagnosis and in some cases at any rate must be amenable to treatment. The commencement of healing had been recognized in two specimens.

In most of the cases recorded in the *Journal of Surgery* the digestion probably began not more than thirty-six hours before the death of the patient; in some cases the duration was much less, reckoning from the occurrence of the haematemesis. The morbid anatomy of the cases showed great variation—from a slight condition in which the phenomena were superficial erosion of the mucous membrane, with haemorrhages into the affected tissue and black fluid in the oesophagus, to cases in which perforation or extreme maceration of the lower third of the oesophagus and extensive digestion of the adjacent surfaces of the lungs had taken place. Nine examples of the most advanced type, five severe but not perforated, and five slighter lesions had been observed—seventeen of them since January, 1914. A most important diagnostic feature available at autopsy was the relatively slight change in the stomach, which might show only slight *post-mortem* digestion or a total absence of that condition, contrasting with advanced digestion of the oesophagus immediately above the cardiac ring. In most cases, at least of the severer types, there was a well marked zone of deep ulceration immediately above the cardiac ring. At a varying distance above this the changes were less of the nature of destruction, the predominant features being superficial erosion and haemorrhages into the mucous membrane, such as were seen in the slight cases. Signs of reaction might be unrecognizable or very slight in the lower parts, but well marked in sections prepared from the upper parts of the damaged oesophagus.

The communication was illustrated by specimens, sections, and lantern slides.

Mr. J. MILL RENTON read a paper on "The surgical treatment of sciatica," which is published in full in our issue of this week, at page 557.

Mr. G. H. EDINGTON read a short account of two cases in which the thoracic duct was wounded in the operation for removal of tuberculous cervical glands:

Case 1.—Early in 1911 he operated on a boy, aged 7, for tuberculous cervical glands involving an extensive dissection on the left side of the neck. The thoracic duct was not seen, and there was nothing unusual in the appearance of the wound at the conclusion of the operation. There was post-operative rise of

temperature to over 100° F., and in thirty-six hours the dressings began to be soaked with watery discharge. On the fourth day the wound was opened and fluid sponged out, and the swelling of very fragile. There was no pus in the wound, and the muscles were peculiarly clean and bare. Death took place on the night of the sixth day, with a copious flow of blood from the wound.

Case 2.—In the summer of 1920 he operated on a lady aged 23. Extensive dissection on the left side of the neck was required, but the thoracic duct was not identified. The following day there was copious watery discharge, and two days later there was ballooning of the lower part of the neck, and through the lower incision there spouted fluid like whey of a pale greenish colour. The temperature rose to 101° F., and as milky fluid continued to pour out, the cavity in the posterior triangle was packed with gauze. The tissues in this case also were macerated. After the firm packing of the posterior triangle the milky discharge became gradually less, and the wound healed without further event.

In the discussion that followed, Mr. ARCHIBALD YOUNG recorded a third case of a man, aged 52, whom he operated on in 1910 for a very extensive tuberculous involvement of the cervical glands on the left side.

Dissection of the glands was carried out laboriously and with much difficulty, and the sterno-mastoid muscle, part of the parotid gland and part of the internal jugular vein were removed in course of the operation. During the operation Mr. Young became aware, through soaking of his gown and the sheets on the operating table with a glairy, sticky fluid, that injury of the thoracic duct had taken place. An attempt was made to find the injured duct, but without success, and in the end recourse was had to packing with iodoform gauze. From the time of the operation there was no further escape of chyle, and on the removal of the packing, which was not disturbed for several days, it was found to be soaked with serum only. The recovery was uneventful.

INDICATIONS FOR BLOOD TRANSFUSION.

At a meeting of the Liverpool Medical Institution held on March 31st, with the Vice-President, Mr. THURSTAN HOLLAND, in the chair, Mr. W. BLAIR BELL discussed the indications for blood transfusion, giving illustrative cases. He divided the conditions for which blood transfusion is required into three main groups with subdivisions.

Group A contains those cases in which there is loss of all the constituents of the blood from an acute large haemorrhage, or the loss of the solid constituents which occurs in chronic limited haemorrhages, or in which there is considerable loss of fluid associated with shock.

Group B contains those cases in which there is absent from the blood some constituent present in normal circumstances, or one usually formed in response to specific stimulation. In this group are such conditions as haemophilia, in which disease operations may safely be performed immediately after blood transfusion. Included also are cases of eclampsia, in the blood of which a chemical antibody to placental toxin is believed to be absent, and acute and chronic infections in which the patient's own bacterial antibodies are insufficient. *Group C* contains those diseases in which there is blood destruction. Although good results are claimed for the treatment by blood transfusion of pernicious anaemia, it is probable that the result is only temporary and that transfusion must often be repeated.

A short account was given of the blood grouping of donors of blood and of the problems which may be connected with the grouping, such as the heteroplastic grafting of tissues and selective sterility. Mr. Blair Bell discussed finally the various methods of blood transfusion, and emphasized the fact that the citrated blood method is the only generally applicable and safe procedure. He then described his own apparatus by means of which the blood of the donors is automatically citrated as it leaves the vein, and all the fluids are kept at body temperature during the necessary steps in the operation. He demonstrated this apparatus to the meeting.

Dr. JOHN HAY read a paper dealing with the prognosis in patients presenting a rapid heart action. Patients with rapid action of the heart could be classed in two groups: (1) those in whom the rhythm was physiological, and (2) those in whom it was pathological. In the first group the rapid action was secondary to such causes as emotion, effort, toxins, etc., and the prognosis depended on an accurate recognition of the primary cause. Special reference was made to the rapid action in patients suffering from aortic regurgitation and also to the apyretic tachycardia of early tuberculosis. The combination of

functional and organic diseases of the heart was discussed. In the second group three conditions were briefly discussed: paroxysmal tachycardia, auricular flutter, and auricular fibrillation, and typical cases were described. The prognosis, both immediate and remote, was carefully considered in each patient and the general principles defined on which prognosis depended.

A NEW ANAESTHETIC.

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine, held on April 1st, with Dr. H. J. SAINLEY, C.M.G., President, in the chair, Dr. R. L. MACKENZIE WALLIS and Dr. C. LANGTON HOWER read a paper on a new general anaesthetic, its theory and practice. Dr. Wallis described the impurities of ordinary ether and previous efforts at the production of ether free from impurities to which harmful effects may be attributed. He alluded to the work of Cotton and to the uselessness of absolutely pure ether as an anaesthetic. The ether which he has prepared, after many different processes had been tried, is distinguished by being free from mercaptans, while it contains the higher ketones, some carbon dioxide, and some ethylene, perfectly pure ether being the vehicle. In the production of this pure ether, permanganate and copper sulphate are employed. The new ether keeps better than the ordinary liquid. The carbon dioxide appears to exercise a stabilizing influence.

Dr. HOWER said that the new agent was less irritating than ordinary ether and stimulated the respiratory system less. He had used it on the patients suffering from bronchitis, none of whom suffered any aggravation of their symptoms. The blood pressure effects were between those of chloroform and of ether. The drop after operation and before consciousness was less than with ether. It had been used successfully on patients with diseased hearts. No ill effects had followed its use with three diabetic patients and with a child who was passing large amounts of acetone. There was absence of taste and smell afterwards and much less liability to vomit. The methods employed had been those usual with ether. Mostly he had used the new agent in connexion with continuous gas and oxygen. It is made by Savory and Moore under the name "ethanesal." Subsequent speakers bore testimony to the satisfactory anaesthesia and freedom from after-effects which they had experienced with ethanesal. It had been used in about 250 cases.

At a meeting of the Laryngological Section of the Royal Society of Medicine on April 1st, with Dr. JOHNSON HORNE in the chair, Mr. ARCHER RYLAND gave an epidiascopic demonstration illustrating a case of pharyngeal pouch dated 1760. Some members doubted whether it was a true pharyngeal pouch, as it was covered by muscular fibres, so that it might more accurately be regarded as a dilatation of the lower part of the deep pharynx. Mr. G. W. DAWSON showed a case of large dental cyst. In the discussion, Mr. STUART LOW doubted if it would heal up without further treatment, and suggested painting the cavity with strong zinc chloride. Dr. DAN MCKENZIE thought that a plastic operation would be necessary. Mr. DAWSON also showed a girl with a retention cyst of the floor of the left nostril. Mr. C. W. M. HOPE showed a patient with a tumour growing from the right supratonsillar fossa. It was agreed that this was probably composed of ordinary tonsillar tissue, and several similar cases were cited. Dr. DAN MCKENZIE showed a case of scarring of the pharynx following scarlet fever many years before, the uvula being moved by contraction to the right side of the palate. Mr. M. VLASTO showed a case of bilateral abductor paresis of the vocal cords. Several members advocated tracheotomy, and Mr. F. HOBDAK, as a result of his veterinary experience, suggested an operation similar to the ventricle stripping performed on "roaring" horses. Mr. PHILIP FRANKLIN showed a case of demyoclops, or lateral nasal proboscis, in a male infant 7 weeks old, and demonstrated the embryological abnormality that had probably occurred to account for the condition. The main points that he called attention to in the case were the absence of the premaxilla, the movement of the appendage, the perforation of the free end, and the secretion of salty fluid. Mr. JEFFERSON FAULDER showed two laryngeal cases for diagnosis, in both of which there was a tumour springing from the region of the ventricular band. They were thought, after some discussion, to be non malignant.

Rebuelus.

THE PHYSIOLOGY OF BONE.

In his treatise on *Bone Formation*¹ which Dr. MARG JANSSEN of Leyden has done us the compliment to write in English, he advances very convincing evidence that tension does not exert any trophic influence on bone. His contention is the result of a careful and extensive study of sections, taken in various planes, of normal and abnormal bones, and his interpretation of the conditions observed prove that he has a very keen appreciation of the close affinity between structure and function.

It is shown, from a study of the neck of the femur in coxa vara, that there is a contrast between the effect of pressure which leads to thickening of the bone elements and tension which produces a thinning of the same elements. A similar contrast is demonstrated in normal bones from several parts of the body and in other pathological conditions. Dr. Jansen explains how previous workers in this field have erroneously ascribed the formation of bone to tension stresses, without taking into account dynamic stresses evolved by muscular action, and cites several examples which show that tension has been assumed in parts of bones exposed to pressure from muscular action.

After surveying the relation of function to the structure of the cancellous tissue in various parts, the author concludes that it is composed of bone elements which coincide with pressure stresses caused directly by muscular action and body weight; and he brings forward evidence to prove that wherever pressure is displaced by tension, atrophy of the cancellous tissue is found. Throughout the book just and arresting criticism, supported by original observations, is levelled at the assumption that tension may promote bone formation. It appears clear that too great emphasis has been laid in the past upon the effect of the purely mechanical forces acting upon bone, and Dr. Jansen undoubtedly brings us back to the living bone and its function; for this reason a study of *Bone Formation* is both refreshing and stimulating, and its facts and arguments will prove of great interest and importance to a wide circle of readers. It is a book from which all anatomists, physiologists, and surgeons may gain inspiration, and even if only a proportion of its readers are prepared fully to accept the doctrine that "to pressure only a trophic effect on bone tissue has been assigned," all will find themselves influenced by the sterling and significant observations made, and be stimulated to look a little deeper into the orthodox teaching on this subject. The book is well and freely illustrated, and a credit to the publishers.

DISEASES OF CHILDREN.

In the third edition of his well known book, *The Clinical Study and Treatment of Sick Children*,² Dr. JOHN THOMSON has taken the opportunity of rewriting the whole and of reviewing all that is best in paediatric literature during the last ten or twelve years. It is quite evident that Dr. Thomson has read very extensively, and that nothing of value has escaped his notice. There may be other books published in this country which make reference in more or less detail to the great and increasing literature—British, Continental, and American—of this department of medicine, but there is no other that provides the reader with the opportunity of seeing it passed in review by a teacher so experienced and of such ripe judgement. For example, Chapter XXII, entitled "On Spasmophilia," gives an admirable account of a condition which for want of separate consideration has been somewhat obscured in textbooks published in this country. The contents of Chapter IX, "On Food Disorders," are subdivided as follows. "Work of Czerny and Keller, and of Finkelstein; Finkelstein's classification; stages of disturbance of equilibrium, dyspepsia, decomposition and intoxication. Causes, symptoms, treat-

¹ *On Bone Formation: Its Relation to Tension and Pressure.* By Dr. Marg Jansen, O.B.E., Lecturer on Orthopaedic Surgery, University of Leyden (Holland). Manchester, The University Press, 1920 (Roy. 8vo, pp. 114; 54 figures, 2s. net).

² *The Clinical Study and Treatment of Sick Children.* By John Thomson, M.D., F.R.C.P. Edin. Third edition, rewritten and greatly enlarged. Edinburgh and London: Oliver and Boyd, 1921. (Med. 8vo, pp. 507; 249 figures, 32s. 6d. net.)

mont. Digestive disturbances from other causes. Diarrhoea from defective nursing; from infection, enteral and parenteral (causes, diagnosis, treatment). Idiosyncrasy for cow's milk." This cosmopolitan outlook is a feature of the book which is very welcome.

Dr. Thomson's sober review of these matters will help to break a way through the strange barrier which seems to exist between the literature of this country and that of others in the subject of paediatrics. In its treatment of the great volume of recent work by English authors the book is no less satisfactory. Chapter XXIV, "On the Heart and Circulation," admirably combines the new learning and the old. References to original papers are provided throughout (in footnotes). The value of the book, however, is much greater than that of a review, however judicious, of current literature. It bears the impress on every page of the author's long experience and great powers of observation. Moreover, Dr. Thomson has succeeded in presenting his material in a form which differs from that which has become stereotyped by its adoption in a long succession of textbooks. While it contains all that a student or practitioner may expect to find in it, the book is truly, as its title indicates, a series of clinical studies.

A lifelong study of the ailments of children enables the author to use very clear and convincing language upon many matters which have not before been made plain. Thus it is usually taught that asthma is not a common disease in early childhood. Upon page 54 is a diagram showing the age of onset in 100 cases. In 60 per cent. the onset was within the first four years of life, in 86 per cent. within the first seven years, in 12 per cent. the disease was already established within the first year. Again, the author makes plain the very great improvement which may be looked for in many cases of spastic diplegia due to cerebral birth injury—cases in which the stiff expressionless face, the speech defect, and the constant dribbling of saliva have given rise to an exaggerated estimate of the degree of mental impairment present. With both of these statements we are in hearty agreement. We believe that it might reasonably be argued that in asthma we have, in most cases, a perpetuation of an infantile neuro-muscular inco-ordination, the disappearance or persistence of which is in great measure determined by the success or failure of the disciplinary and moral education of the child, and that the cerebral damage which gave rise to the spastic diplegia, in many cases, produces only a motor defect, leaving the receptive side of the brain unimpaired, although for long unstimulated because of the motor abnormality.

In a book so full of clear and precise, though guarded, statement there is little which invites criticism. We doubt if it is true that "a child should not usually be allowed to bathe in the sea until he is six or eight years old"; but perhaps Dr. Thomson has in mind the frigid seas of his own east coast of Scotland. We think that the short paragraph entitled "Practical Details regarding Breast Nursing" might profitably have been expanded into the most important chapter in the book. The numerous illustrations are excellent. Such plates as those illustrating "The facies in pleuropneumonia before and after the crisis" (p. 7), "Chorea at the onset and in convalescence" (p. 590), and "Nodules in the scalp in rheumatic fever" (p. 735), are an advance upon what is commonly achieved.

Dr. Thomson's book will be of real service to the practitioner and to the student of medicine. So long as the subject of paediatrics is crowded out of the medical curriculum, we must look to books such as this to repair the damage, and, so far as may be possible, to keep alive interest in and to spread understanding of a subject of unequalled importance to the community and the race.

TREATMENT OF VENEREAL DISEASE.

The fourth edition of Marshall's *Syphilis and Venereal Disease*³ appears under the joint authorship of C. F. MARSHALL and E. G. FRENCH. The book has been thoroughly revised throughout and much new matter

added, especially in the sections dealing with treatment. New plates have been inserted and the work is well illustrated, although we should have welcomed a few more illustrations in the chapters devoted to syphilis of the eye and of other special regions of the body. In discussing treatment the authors make a special plea for the internal administration of mercury, a method that has been disparagingly referred to by some writers as the "pill treatment." They point out, in support of their views, that:

The two syphilologists who have probably treated the greatest number of cases—Sir Jonathan Hutchinson and Professor Alfred Fournier—employed this method in the great majority of their cases. Further, as these two syphilologists have enjoyed an unusual span of active professional life, they have been able to follow up their cases to an extent which is denied to most of us and have shown that the proportion of tertiary syphilis occurring among their cases after prolonged internal treatment is small, and compares favourably with that of other methods. In fact, the most reliable statistics we have concerning the frequency of tertiary syphilis (those of Fournier) are based on cases which were, for the most part, treated by ingestion. Hence the incidence of tertiary syphilis appears to depend less on the method than on the duration of mercurial treatment.

In the section describing exfoliative dermatitis resulting from arsenical preparations the authors consider cold or exposure an important etiological factor. During several years' experience in India and London only four cases of severe dermatitis were observed, but during service in France some twenty cases came under observation. The authors suggest that the majority of these cases were due to exposure to cold. They do not, however, give details as to the amount and intensity of the treatment to which these patients had been subjected. Intramine is recommended as the best remedy available for such cases. In the chapter on inherited syphilis several of the illustrations are reproduced from Findlay's excellent little work on *Syphilis in Childhood*. A chapter is devoted to the subject of chancroid. In the difficult matter of treatment the authors recommend the method of Goubeau. This form of treatment was extensively carried out in the French army and apparently with success. It consists of carefully cleaning the surface of the chancre with a swab soaked in ether and of afterwards applying by means of a brush or a wooden probe wrapped in wool a 1 in 50 alcoholic solution of sodium arsenate.

In the chapter on gonorrhoea the illustrations are mainly taken from Luys's well-known work on that subject. The important question of tests for cure scarcely receives the attention it deserves, only a few lines being devoted to a subject which is surely one of the most vital in the whole of venereal science.

In the final chapter, on venereal disease and public health, the authors come to the conclusion that among the measures calculated to reduce the incidence of venereal disease in the community prophylaxis is of primary importance.

THE QUANTITATIVE STUDY OF METABOLISM.

ALTHOUGH long before the war the quantitative study of metabolism had been enriched by the contributions of many physiologists, it is certain that the war-time stringency of food conditions encouraged many to undertake this kind of research who were previously deterred both by the apparent difficulty of the technique and the improbability of attaining any results of dramatic interest. But the researches of Haldane, Pembrey, and Douglas had placed at the disposal of the investigator a method which did not involve the provision of a large quantity of expensive apparatus, and which could be accurately employed by any person who had had a general scientific training and a few months' special instruction. The system to be recommended was succinctly described by Cathcart in a paper which appeared in the *Journal of the Royal Army Medical Corps*, November, 1918, and several English workers reported observations upon the metabolism of healthy adults under varying conditions. For the most part, the circumstances in which these observations were made precluded accurate study of the basal rate, a function which has been elaborately measured by American physiologists, although Cathcart and Orr were able to report upon the post-absorptive rates of a sample of healthy adults. It was obvious that variations of the basal rate in health and disease would repay further investigation, and Drs. BOOTHBY

³ *Syphilis and Venereal Diseases*. For Students and Practitioners. Being the fourth edition of *Syphilology and Venereal Disease*. By J. F. MARSHALL, M.D., M.Sc., F.R.C.S., and E. G. FRENCH, M.D., Ch.B., F.R.C.S. Edin. London: Baillière, Tindall, and Cox. 1921. (Demy 8vo, 446: 90 figures, 9 plates. 25s. net.)

and SANDIFORD⁴ have been well advised to issue a manual for the service of those who wish to introduce calorimetry into the sphere of clinical research.

The authors have had wide experience of clinical calorimetry at the Mayo Clinic, and remark that: "In the treatment of the large number of thyroid cases seen at the clinic our results have definitely shown how essential is the knowledge of the basal metabolic rate in pathologic conditions of the thyroid. It is as essential as a knowledge of the temperature in febrile cases." The volume is avowedly a laboratory manual, and does not deal with the clinical interpretation of results. The technique described and advocated is essentially the same as that of Haldane and Douglas, of Cathcart and Orr, and of other recent English workers, with the modifications imposed by its application to persons at rest in bed. The only substantial change is the employment of a gasometer for measuring the volume of expired air, instead of the rougher and handier method of expressing the contents of a bag through a meter. Whether the gain in precision more than compensates the loss of simplicity must be decided by future experience. The authors describe each step of the routine clearly and fully, and provide tables which will be found very useful by the computer.

We think it well to conclude upon a note of warning. There is an old legal motto that he who seeks equity must do equity, which has an application here. Those who desire to ground clinical or physiological inferences upon quantitative measurements must give heed to the determination and limits of accuracy of their "normal" standards. Quite recently Harris and Benedict called attention to the weakness of some arithmetical arguments which have passed current in physiological circles. Perhaps the criticisms of the last-mentioned authors were in some particulars over-emphasized, but of the importance of the principle for which they contended we entertain no doubt. We do not believe that this method will be of value as a routine procedure until the discussion of the statistical significance of normal variations of basal metabolism initiated by Benedict and Harris has been carried a good deal further.

A TEXTBOOK OF DERMATOLOGY.

DR. MACLEOD'S *Diseases of the Skin*⁵ is one of the most important works on dermatology produced in this country in recent years. During the period that Dr. MacLeod has worked at his subject he has not neglected to study the writings of his colleagues and contemporaries; to this the present volume bears ample witness. References will be found therein to almost all the principal modern contributions to dermatology, although the author states that owing to the exigencies of space the bibliographies have been restricted. This textbook is, however, by no means a mere compilation, for although the author has done full justice to the work of others his own individuality and personal standpoint are visible from start to finish.

The book is singularly complete, for after a fairly exhaustive examination we have not detected any really important omission; another merit is that the amount of space allotted to the various subjects is very well adjusted to their relative degrees of importance. Dermatology is notoriously a subject overlaid with masses of detail, and to a large extent consists of the record of isolated facts which as yet do not admit of satisfactory classification. But while as a collector of facts and descriptions Dr. MacLeod need fear no comparison even with the Teuton, he has not allowed them to obscure his clarity of thought, and he has been able to maintain a unified conception of the whole field of his art. We would particularly commend to the student a perusal of the chapters comprising Part I, which includes the sections on general pathology, diagnosis, and treatment, both internal and local. They are full of sound principle and reasonable advice. Consideration of them will tend to steady the therapeutic head and prevent over-confidence in the claims of so called "specifics" which from time to time become prominent in the dermato-

logical world. But, in classifying local medicaments into therapeutic groups, Dr. MacLeod should give more prominence to the protectives group, for these, which consist (as he states) of bland powders, thick ointments, and occlusive dressings, are the most important class of local therapeutic agents for application to the skin. The skin itself has for its chief function the protection of the underlying structures, and when it becomes inflamed it needs above all things protection itself in order to give the physiological rest which is the first rule in the treatment of inflamed organs. In the list of local medicaments in common use in dermatological practice there is, too, one curious omission, namely, zinc. Is it possible to practise the treatment of skin diseases at the present time without employing that metal either as an ointment, lotion, or powder?

No satisfactory classification of diseases of the skin has yet been devised. In this volume the etiological system is followed as far as possible, but when that has been pushed to its utmost limit there remain a host of conditions as to the causation of which nothing is known, and a place has to be found for them. Dr. MacLeod has grouped them to some extent regionally in chapters on affections of the hair, of the nails, of the lips, etc. He has also three very excellent chapters on neoplasms—one on benign neoplasms, another on malignant neoplasms, and a third on pseudo-neoplasms, under which term he groups the various forms of xanthoma, scleroderma, and calcareous deposits. These three chapters may be especially recommended to the attention of young surgeons and pathologists. They are well illustrated by drawings made by the author's pencil from his own sections. As one of the few British dermatologists who has made his mark in pathology he perhaps shines more particularly in this branch of the subject. Finally, there is a chapter devoted to tropical affections of the skin; this includes a miscellaneous collection of conditions which have in common simply the fact that they occur in warm climates. Many of these might well have been grouped more scientifically, for their etiology is well known; this is true, for example, of oriental sore, framboesia and others. A minor fault in the classification is the inclusion of Schamberg's disease under congenital abnormalities. Not many will admit that this is a correct view of it.

Illustrations form an important part of dermatology, and they have been lavishly provided in the present instance. Curiously enough, the monochrome photographs, on the whole, are of a far higher standard and give a much better idea of the conditions they depict than do the coloured plates, which have apparently been made from drawings, not from photographs. Too much stress is laid upon the necessity of having books on dermatology illustrated in colour; very often the coloured illustrations fail to give a better idea of the lesions described than ordinary photographs, and sometimes they are positively fallacious. To be really useful they must be made either from the very best photo-transparencies, preferably Lumière autochromes, or from coloured drawings executed with a very great deal of labour by a highly skilled artist who has more time to give to the task than is usually available.

The literary style of the book is good; it is very readable, and the descriptions are often very happy. The author is to be congratulated on his work, which is a credit to British dermatology.

HYPNOTISM.

IN *An Introduction to the Study of Hypnotism, Experimental and Therapeutic*,⁶ by Dr. H. E. WINGFIELD, the practitioner who wishes to utilize this form of treatment will find a useful guide. The book is clearly written and essentially practical. The earlier chapters are devoted to definitions, the conception of the subconscious, the methods of inducing hypnosis, and the various phenomena of the hypnotic state. These more theoretical matters are followed by a long chapter in which the question of treatment by hypnotic suggestion is discussed. While the author has found hypnotism to be a valuable therapeutic agent in a number of nervous conditions, he is fully alive

⁴ *Laboratory Manual of the Technique of Basal Metabolic Rate Determinations*. By Walter M. Boothby, A.M., M.D., and Irene Sandiford, Ph.D. Philadelphia and London: W. B. Saunders Company, 1920. (Metabolic rate and basal metabolism. 25s. net.)

⁵ *Diseases of the Skin*. By J. M. MacLeod, M.D., F.R.C.S. London: Black and

⁶ *An Introduction to the Study of Hypnotism, Experimental and Therapeutic*. By H. E. Wingfield, M.A., M.D., B.Ch. Cantab. Second edition. London: Baillière, Tindall, and Cox, 1920. (Crown 8vo, pp. viii+195. 7s. 6d. net.)

to its limitations, and writes with balance and restraint. Especially does he lay stress on the thesis that, though hypnotism may do much to begin a cure, the ultimate result must depend upon the personality factor. He shows that many nervous conditions are the product of an unhealthy manner of life, that the patient must himself strive to overcome his tendencies to indolence and self-indulgence, and that only by an endeavour to face the realities of life will he succeed in contributing his share to the welfare of the community.

PREVENTION OF COMMUNICABLE DISEASES.

MANY authors have written upon preventable diseases, but hardly one has dealt with the subject in such a thorough and comprehensive manner as Dr. FRANCIS M. MUNSON in his *Hygiene of Communicable Diseases*.⁷ It deals not only with such infectious diseases as measles and scarlet fever, but with many other ailments which are best described as communicable. Its scope is further shown by the author's statement that successful defence against infection is much more a personal affair than it was formerly considered, and that individuals can and must protect themselves. "If," he writes, "people practised reasonable cleanliness and put nothing in their mouths except what belonged there, most communicable diseases would be avoided." Cleanliness and disinfection are so nearly allied that we turn with interest to the chapter in which Dr. Munson deals with the latter. He describes the ordinary methods of disinfection, but considers that disinfection after a case of measles, diphtheria or scarlet fever is largely unnecessary, and that it is a waste of time, energy and money to attempt to disinfect the air of a sick-room while it is in occupation.

The chapter upon railway sanitation deals with the American Interstate Quarantine Regulations, which are so crowded with detailed instructions to railway employees and passengers that their very multiplicity seems calculated to defeat the object for which they were made. The all-embracing nature of these regulations may be gathered from the inclusion in them of sections dealing with the disinfection of shaving brushes as a safeguard against anthrax.

A very useful chapter is that concerned with the sanitary measures to be taken after great disasters such as floods, fires, and earthquakes. Very practical and well considered advice is given as to the improvisation of water supplies, the emergency removal of refuse, and the promulgation of sanitary regulations in the event of the occurrence of such disasters. The author enumerates several measures which in his opinion are among those essential for the prevention of venereal diseases. These include education in matters of sexual hygiene, provision for accurate and early diagnosis and treatment, repression of prostitution by the police, restriction of the sale of alcoholic beverages, abandonment of the use of common towels in public places, and personal prophylaxis by those who expose themselves to the risk of infection. On the debatable question of compulsory notification of cases to the sanitary authority he is silent. Although obviously written for American readers the book will be of value to public health officers on this side of the Atlantic, if only because it will enable them to compare American administrative procedure with British, and not always to the advantage of the latter.

NOTES ON BOOKS.

THE fortieth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*⁸ contains the proceedings of the Society during the session 1919-20, and those also of certain other bodies affiliated with it. In addition to individual papers the two discussions held by the Society are—the one on diabetes in relation to diseases of the eye, and the other on the prevention and treatment of ophthalmia neonatorum. It may be remembered that at the end of this discussion the Society adopted a resolution asking the Metropolitan

Asylums Board, in view of the large number of cases of ophthalmia neonatorum congregated at St. Margaret's Hospital, to afford facilities at that hospital for teaching medical students, midwives, and district nurses the natural history and treatment of the disease. The report of the council of the Society calls attention to the increased cost of publishing and printing; in consequence the annual subscription has been increased to 31s. 6d., and a reserve fund for publication, to which gifts are invited, has been established. Of the affiliated societies whose proceedings are embodied in the volume the first is the Oxford Ophthalmological Congress of 1920. The material published from this congress includes the Doyne memorial lecture on the nerve paths and centres concerned with sight, delivered by Mr. Richardson Cross of Bristol. The other societies whose proceedings are reported are the Midland, the North of England, the Irish, and the Egyptian Ophthalmological Societies. The last fifty-six pages of the volume are occupied by a general index to the *Transactions of the Ophthalmological Society* for the ten years 1911-20. The preparation of this index has, it is stated, led to some delay in the publication of the volume.

The eleventh edition of the well-known ambulance handbook, by Drs. WARWICK and TUNSTALL, entitled *First Aid to the Injured and Sick*,⁹ brings this little volume into its 150th thousand. The text and illustrations have been revised, and the new edition should maintain the popularity which this work has earned during the twenty years it has been before the public.

A small manual, *Serbo-Croatian Self-taught*,¹⁰ by Mr. JOHN O'BRIEN, has now been included in the Marlborough Series. Serbo-Croatian is the language of the kingdoms of Serbia and Montenegro, of Bosnia and Herzegovina, of Dalmatia, Croatia, and Slavonia, and of certain parts of the south of Hungary; it is spoken by some nine millions of people. The main distinction between Serbian and Croatian lies in the different alphabets employed. The only other differences between the two are trifling details of dialect and pronunciation. Serbo-Croatian is thus one language with two alphabets. Both renderings are given in this little volume, but all the words are transcribed phonetically.

⁷ *First Aid to the Injured and Sick*. By T. J. Warwick, B.A., M.B., and A. O. Eleventh edition, revised. London: Simpkin, Marshall, Hamilton, cap. 8vo, pp. 260; 301 figures.

⁹ *First Aid to the Injured and Sick*. By J. J. R. Self-taught Series. London: E. Marlborough. Ill. Wrapper, 3s. net; cloth, 4s. net.

APPLIANCES AND PREPARATIONS.

Two Instruments for Genito-urinary Surgery.

MR. JAMES MACMUNN (London) writes: The upper figure in the diagram below represents the combined massage and douching instrument for the prostate recommended by me in the correspondence columns of the *BRITISH MEDICAL JOURNAL* of January 22nd, 1921, page 142. The large massaging bulb—as large as the anal canal will admit with comfort—presses the secretions from the prostatic ducts, and at the same time aids the circulation of the haemorrhoidal plexus and the prostate, and higher up, the circulation of the vesico-prostatic plexus, which the finger cannot do. With this massage there is combined a strong stream of hot saline water, followed if desired by cold, upon the surface of the prostate. Thus, we have a means of alleviating congestion, resolving the inflamed tissue, and increasing muscular tone. The second figure represents a useful addition to prostatic massage, which must be used only by the surgeon. It is a long flat sound, as broad as the urethra will admit (I use three sizes), ending in a large bulb. The prostate is massaged against the convexity of the instrument. Hitherto Kollman's dilators were supposed to afford the best means of opening and emptying the ducts of the urethra, which is the chief consideration in the treatment of gleet, but, while this dilator can open follicles, it certainly cannot empty them, nor can suction. In my opinion, the only way to empty follicles is to massage them over flat sounds, preferably by means of a rubber roller. The instruments are made for me by the Holborn Instrument Company.

An Appendix Clamp.

Mr. W. K. IRWIN, F.R.C.S. (London, W.), writes: In appendicectomy the usual routine is to apply two pairs of forceps and divide the appendix between them. By this procedure appendix contents are forced into the part between the

⁸ *Hygiene of Communicable Diseases*. By FRANCIS M. MUNSON, M.D. 8vo, pp. 807; 36 figures. 5 50 dollars.
⁹ *Transactions of the Ophthalmological Society*. Vol. XL. Session 1919-20, with list of officers, members, etc. London: J. and A. Churchill. 10s. net.

two pairs of forceps, and to prevent the spread of infection the surgeon is compelled to resort to the inevitable "drop of pure carbolic." To avoid this trouble I have devised the instrument depicted, which is as easy to apply as any pair of forceps. The clamping part of the instrument is wide enough (9 mm.) to allow the base of the appendix to be ligatured and divided in the part crushed, the peritoneal surfaces of which are brought

into a
from t
of the
transversely. To avoid any risk of injuring the peritoneum the serrations, while strong enough to effect their purpose, are very fine, and have their ends carefully rounded off. In my opinion clamps with smooth unserrated surfaces which act equally in all directions, unless they are narrow like Mr. Donald Armour's ingenious instrument, tend to produce a longitudinal rupture of the appendix. The ratchet catch and spring are similar to those used in various forms of needle holders, and are locked and unlocked with the greatest ease. The clamp has been made in accordance with my suggestions by Messrs. Arnold and Sons.

Catheter Holder for Intrauterine Treatment of Gonorrhoea.

Dr. RIVINGTON HOBBS, Medical Superintendent, Kensington Infirmary, writes: Since my article on the treatment of gonorrhoea in women appeared in the *Practitioner* last January I have had many more cases under treatment. In order to facilitate the introduction of the catheter into the fundus uteri I have devised a catheter holder, as illustrated. It is a light,

handy instrument for introducing a small terminal eyed catheter into the uterus. It has the advantage that, owing to its size and to the bend in the shaft, the line of vision of the catheter is not obscured. When the catheter has been inserted the lumen of the tube is not obliterated, so that the fluid can be swung through whilst the tube is retained *in situ* by the holder. The instrument has been made for me by J. H. Montague, 69, New Bond Street, W.1.

INTERNATIONAL RED CROSS CONFERENCE.

THE tenth International Red Cross Conference at Geneva was closed on April 7th; it accomplished a great deal of work, but the practical results will only be seen after the various national societies have had time to consider and act upon the recommendations made.

The conference unanimously adopted resolutions inviting national governments to make additions to the Hague Convention absolutely forbidding the use of poison gases, whether as drift gases or in projectiles, and limiting war in the air to strictly military objects, so that the civil population may be as far as possible protected from this new weapon, and useless destruction avoided. A resolution, proposed by Mr. Frank Hastings, asking the governments to take steps to add to the International Convention rules governing the protection of aeroplane ambulances and air ships used for the carriage of sick or wounded, was adopted.

A recommendation, asking that a clause should be added to the Hague Convention forbidding the bombardment of undefended places, led to a good deal of discussion; it was finally adopted, as was also the suggestion from the Swedish and Danish Red Cross Societies that the rules should permit supplies to pass through a blockade to sick persons, old people, and children, although the difficulties in the way of carrying out this recommendation were recognized.

Among the resolutions adopted with regard to Red Cross work in peace was one to the effect that Red Cross societies should organize help for persons crippled in civil life, and that such help should include the establishment of special hospitals providing prosthetic apparatus and instruction in

suitable trades. A resolution proposed by Sir John Lynn-Thomas, who had read a paper on the subject describing what had been done at the Prince of Wales's Hospital, Cardiff, for Wales, was approved by the appropriate committee and adopted at a meeting of the full conference. It set out that Red Cross societies should deal with the pressing problem of civilians who have lost a limb, in order to extend to them the benefits of the organized treatment which was for the first time established during the war to meet the needs of crippled soldiers and sailors.

A committee was appointed to consider the part the Red Cross should take in civil war; it recommended that the Red Cross Society of the country in which civil war prevailed should not be authorized to ask directly for help from the Red Cross societies of other countries, but only through the International Red Cross Committee. Discussion arose on several occasions during the course of the conference with regard to the present position in Russia. The International Red Cross Committee had been prepared to recognize the Russian Soviet Red Cross Society, but the president of that society made difficulties in attending and did not attend. Representatives of the old Russian Red Cross were present. Eventually resolutions were adopted by the conference calling the attention of the people of all countries to the fact that a state of civil war does not justify the violation of ordinary human rights, and protesting against the system of taking political hostages from among the families of accused persons, as also against the cruelties inflicted upon prisoners and upon persons interned during the civil war in Russia. The committee appointed to deal with matters affecting prisoners of war found the number and complexity of the questions raised too great for its resources; and M. Dimichert, representative of the Swiss Government, informed the conference that he had reason to hope that the Swiss Federal Government would take steps to bring about a diplomatic conference on the subject.

Before separating, the conference expressed the hope that the International Red Cross Committee would receive sufficient pecuniary support from the various countries, and that in future international congresses would be held at shorter intervals.

The Red Cross societies of the following countries were represented at the conference: America, Argentina, Australia, Austria, Brazil, Bulgaria, Canada, Chile, China, Denmark, Estonia, Great Britain, Greece, Germany, Hungary, Holland, India (British), India (Netherlands), Italy, Japan, Latvia, Luxembourg, Mexico, New Zealand, Norway, Poland, Portugal, Rumania, Serbia, Siam, Sweden, South Africa, Spain, Sweden, Switzerland, Czechoslovakia, Venezuela, Turkey. An asterisk indicates that the Government of the country was also represented. In addition the following Governments were represented: Columbia, Ecuador, Haiti, Peru, Persia, Uruguay. The Papal Nuncio was present in a consultative capacity, as were also representatives of the Red Cross Societies of Rumania, Lithuania, and Ukraine, the International Labour Bureau, the American Relief Administration, and the Save the Children Fund.

As already stated, an agreement defining their respective spheres of work has been reached between the International Red Cross Committee and the League of Red Cross Societies. The latter was represented at the conference by the Director General (Sir David Henderson), the Medical Director-General (Professor C. E. A. Winslow), and other officers.

A BRITISH home for necessitous Austrian children is being established on the estate of Klessheim, granted at what is described as a nominal rent by the provincial government of Salzburg. The home contains thirty children, but could accommodate five hundred were equipment and funds available. There is a British director, with a staff of trained nurses and other helpers. The parents are asked to contribute to the cost, and the American relief administration gives one meal a day. In this connexion it may be noticed that the American Relief Fund has sent Professor Pirquet 10,000 dollars to purchase food for the families of the lecturers in medicine at Vienna. The sum has been divided among two hundred families, who have consented to adopt Professor Pirquet's dietetic method described in our columns of October 30th, 1920.

British Medical Journal.

SATURDAY, APRIL 16TH, 1921.

THE EPIDEMIOLOGY OF TUBERCULOSIS.

As we have frequently pointed out, opinion respecting the epidemiology of tuberculous diseases has changed enormously within the last decade; no better illustration could be afforded than by the recently published work of Colonel Bushnell, a distinguished officer in the United States Army Medical Corps.¹ Though he modestly disclaims any authority conferred by the prosecution of original research, his essay is not the less valuable as a clearly written and even weighty contribution to the literature.

His main argument will not be novel to readers of Professor Calmette's papers and was restated with additional evidence by Colonel Lyle Cummins a few months ago. But Colonel Bushnell has covered a wider literary field, and his familiarity with American military and other official reports enables him to furnish information which is not available to most English readers. Expressed in a few sentences, his argument runs as follows: There is a fundamental distinction between the epidemiological behaviour of tuberculosis in races recently exposed to infection and amongst populations wherein the disease has prevailed for generations. Amongst the former alone do epidemics comparable to those of zymotics occur, and amongst them variations of climatic or hygienic conditions are factors of but minor importance. On the other hand, amongst acclimatized races the mortality of tuberculosis varies with the hygienic conditions and therefore, to a large extent, with social status. Not to speak of examples, such as that of the Kalmucks, which have frequently been quoted before, the contrast between the experience of the American negro and the American Indian is a striking illustration of the author's argument.

Colonel Bushnell is led to conclude that any attempt to eliminate sources of infection in settled countries would, if successful, be positively injurious. "Supposing," he writes, "that with extraordinary energy and sagacity we banish all tuberculosis from our town and rear an absolutely uninfected group of children. Having passed a childhood under the irksome restrictions that would be necessary, the time must come when they shall be permitted to enter the outside world, for the fear of disease cannot remain the paramount consideration during life. As soon as, now adults or adolescents, they leave the sheltering confines of their native town they will be exposed to the dangers of primary tuberculous infection, and that at an age when the world beckons most invitingly, and when prudence is least developed! In fact, they would be in a hardly less dangerous situation than the tropical native when he first enters a civilized community. Prophylaxis has simply resulted in exchanging the danger of a chronic and usually relatively benign infection for the danger of an acutely fatal infection." Colonel Bushnell thinks, in fact, that we should strive to substitute "an

artificial premeditated infection for the present infection by chance," but he perceives that we have not as yet nearly sufficient knowledge to justify any such proceeding. We need, he thinks, to study the later history of those who were positive to the von Pirquet reaction, and compare it with the fate of those not responsive to the test in successive years of age. He would have a careful record kept by name of all the children that have been tested, and the history—particularly, of course, the tuberculosis history—of each child should be followed at least up to the 30th year. "It being ascertained," he says, "that a given child has recently become infected, proper steps can be taken to ensure the best possible care for it, to the end that the infection may remain latent. There can be no doubt that the first half-year after infection is a critical time for the child. Proper attention at this time would do more to lower the morbidity and mortality from tuberculosis than anything except preventing the infant from coming into contact with the consumptive. The work would be of great value if limited to the acquisition of data to be utilized only for the prophylactic care of recently infected children. We should, however, aspire to more. What an enormous mass of valuable data is lost because acquired a little at a time by many individuals, and never collated!"

Colonel Bushnell's opinions respecting the dangers incurred and the precautions to be taken when uncivilized races are brought into contact with the civilized, especially his strictures upon the impolicy of introducing consumptives from an old country into the midst of a virgin race, will command universal assent, but his observations upon the present and future of antituberculosis measures in an industrial population will not be so generally approved. It will, for instance, be argued that the danger of massive infections in adult life has not been sufficiently considered. In England and Wales (1910-12) the standardized mortality from tuberculosis of shoemakers was 456 per cent. of that of clergy; printers and bookbinders were nearly as bad; bricklayers had only 273 per cent. and coal-miners only 163 per cent. of the best attainable rate. It is not possible to argue that the domestic standard of life amongst bricklayers and coal-miners is far superior to that of printers and shoemakers, or that in childhood prophylaxis has been more efficiently carried out by "nature" for the children who are to become bricklayers than for those who will develop into printers. Hence we must suppose that either (a) physical occupational selection, (b) the hygienic conditions of labour, in Dr. Leonard Hill's sense, or (c) opportunities for massive infection, or all three factors combined, are enormously important factors of etiology.

The ultimate solution of the tuberculosis problem is not likely to be found in an expedient theoretically so simple as the deliberate immunization of the whole race during childhood.

Colonel Bushnell considers that one of the most dangerous doctrines relating to prophylaxis is that good health prevents tuberculous infection. He admits that good health will prevent tuberculous infection from becoming tuberculous disease, but denies that good health has anything to do with the reception of the tubercle bacillus into the body. This is, we think, literally true, and an important warning when the contact of virgin races with the civilized is in question. But it must not be misinterpreted into a suggestion that within a civilized community any measures whatever can be of higher importance than those destined to secure a high standard of physical and mental efficiency in the popular sense.

¹ A Study of Tuberculosis, with Especial Reference to the Tropics and of the Negro Race. By George E. Bushnell. London: Bale, Sons and Danielsson, Ltd. 1920.

As we said at the outset, Colonel Bushnell's work expounds a philosophy of tuberculosis very different from that which flourished but a few years since; it is, we think, a truer philosophy, but there is still need of a wider basis and a risk lest the new doctrine should tend to a particularism, a narrowness, which was the fate of its predecessor.

THE PHYSIOLOGY OF PAIN.

UNTIL comparatively recent times the problem of pain has been a subject of philosophic speculation rather than of physiological study. The philosopher has usually approached the question under the conviction that pain must necessarily and, however indirectly, have value and meaning for mankind. A recent review¹ observes that philosophical methods and conclusions are unsatisfying to the biologist, who is met at the outset by the fact that there is an enormous discrepancy between the amount of experienced pain in the world and any observed physical, mental, or moral benefit that ensues to the sufferers. It has often been assumed that, within limits, sensitiveness and liability to pain constitute conditions tending to favour survival. These assumptions cannot be unreservedly accepted. It is not correct, for instance, to regard pain as invariably related, as to its origin and continuance, with some definite underlying abnormality of which it is a more or less precise expression and measure.

Certain peculiarities in the status of pain are not difficult to detect, and they may be indicated in three broadly defined groups. The first of these peculiarities is the frequency of pain. It is the commonest disturbance of well-being to which man is subject. Even the healthiest of us will find that, quite apart from injury, scarcely a day passes without some transient twinge or stab or ache that easily lapses from a healthy memory because it is unaccompanied by any other evidence of abnormality.

The second is the relation of pain to its bodily cause. Pain is of all symptoms the one most likely to be persistent and inveterate. The longer it persists the more difficult it is to relieve, though the originating lesion has ceased to exist. It seems almost as if when pain has been present for a long time it became as it were ingrained in the very substance of the nervous system, and rendered truly ineradicable.

The third peculiarity concerns its functional value. Within the comparatively narrow limits of recoverable injury pain furnishes the patient with guidance whereby life or activity may be preserved. We see proof of this in the damage that may ensue when the sensibility to pain is lost, in such diseases as tabes and syringomyelia. But it soon becomes obvious that a sharp distinction must be drawn between pain in relation to disease and pain in relation to injury. In the majority of diseases it is no more than an arbitrary and superadded affliction. Certain diseases consist, as it were, entirely of pain; in trigeminal neuralgia and the pain that sometimes follows amputation the one symptom constitutes the whole disease. Such cases exemplify the very acme of the functional uselessness of pain. A superficial examination of the symptom as met with in practical medicine furnishes a fair body of evidence that it occupies a remarkable, an even unique position.

The study of pain in the normally innervated skin has yielded certain definite and well established facts which justify the general statements that the

peripheral pain mechanism is excitable by a number of different stimuli which have no single physical character in common. While the stimulus required is relatively intense, the consequent reaction is relatively excessive. The most remarkable feature, however, is anatomical; the peripheral pain end-organ differs from all other end-organs in being a mere free and naked terminal arborization. A specialized end-organ is to be regarded as at the same time increasing accessibility to one specific stimulus and diminishing it to all others. Of the other specific sensory spots in the skin each is accessible to one stimulus alone. The touch spot responds to movement, the heat spot to transference of heat to the skin, the cold spot to transference of heat from the skin. But the pain spot is accessible to stimulation by all of these, with the reservation that the mechanical stimulus that would excite a touch or thermal spot has to be increased in intensity in order to stimulate a pain spot. That is to say, the threshold of the pain spots is relatively high, and when the threshold is reached the sensation "pain" seems suddenly to burst upon the sensorium with a veritable explosion of reactive energy. This explosive quality of the sensation of pain constitutes one of the chief features distinguishing it from other sensations, which in the main possess mere "recognition" qualities.

After simple division of a nerve, as in amputation, an outgrowth of axis-cylinders occurs from the central end into the surrounding tissues. The nervous elements seem to seek to invade, the connective tissue elements to restrict the invasion, and each seems to be excited to activity by the other. The invading axis-cylinders fail to obtain the requisite insulation which appears essential to all peripheral nerves, they fail to find a termination in appropriate end-organs, and remain to all intents free and naked arborizations of neural tissue in somatic tissue, and come to resemble in that respect "pain" end-organs. Thus they become exposed to constant subliminal excitation, and this fact perhaps explains that intensification of sensibility met with in recovering areas which makes all forms of stimuli result in sensations akin to pain. All other end-organs than those of pain have their terminal fibrils shut in by a well-marked encapsulating formation. This completeness of insulation may be a means of damping down the general excitability of such nerves so that the sensations they originate shall be without urgency and explosiveness, and permit of that quiet sensory atmosphere in which alone deliberation and discrimination are possible.

The review concludes with an attempt to trace out the way in which the evolution of common sensation has proceeded. The germ of a nervous system is a group of cells capable of irritating and being irritated by the other cells of the body. The essential hostility of neural and non-neural tissues gives us, perhaps, a hint of the physiological significance of the ectodermal origin of the nervous system, and of its being formed at the surface and then sunk *en masse* into the substance of the embryo. The opportunities for contact between the two tissues require limiting and regulating. As we ascend higher in the animal scale we find an extended series of increases in the centralization and insulation of the nervous system, centralization rendering the insulation easier, until we see in the human nervous system how very elaborate and complete the mechanisms securing this condition have become.

In animals with a diffuse nervous system response to stimulation seems to be for the most part immediate and urgent, so that what sensation there is in such animals is all of the quality which survives in

¹ Medical Science, Abstracts and Reviews, 1921, iv, 43.

man only as pain. Delay between stimulus and response is possible when improved insulation has damped down the urgency of incoming sensation; as soon as delay is possible deliberation and discrimination appear. Sensibility to pain, it is suggested, is the survival of the primordial mode of sensation. Its urgency and tendency to evoke immediate motor response is the reproduction of the normal experience of the lower invertebrates. From it the discriminative forms of sensibility have been differentiated by the progressive increase of insulation. Regeneration of a nerve by exposing a greatly increased number of nerve fibres to somatic contact and irritation throws back all forms of sensibility more or less into the primitive type and provides an explanation of the characteristically variable phenomena of recovery after suture. If we view pain as an exaggerated response by a physiologically irritated nerve, it is possible to get some conception why pain is the commonest of symptoms, and why it is apt to become inveterate. Pain is, as it were, physiologically just not present in us all, and what appears to be a very slight disturbance pathologically may prove an effective and incurable excitant of it.

THE EVEREST EXPEDITION.

For the past few months preparations have been in active progress for the expedition, organized jointly by the Royal Geographical Society and the Alpine Club, to explore Mount Everest, the highest peak in the world. The preliminary survey and the subsequent ascent have been made possible by the permission of the Tibetan Government for the expedition to enter Tibet. Hitherto no mountaineer has reached within about sixty miles of Mount Everest, and the northern approaches to this and the neighbouring Himalayan peaks have never been surveyed; the advance through Tibet will therefore break wholly new ground. Apart from the difficulties of travel in remote and unexplored mountainous districts, the two chief problems appear to be the maintenance of supplies and the preservation of health and vigour at great altitudes. Recent work in physiology suggests that the key to success is an adequate supply of oxygen and of foods rich in vitamins, but the transport of oxygen in bulk over mountainous passes would be a formidable undertaking. It is estimated that on the summit of Mount Everest the rarefied air contains only one-third of the usual amount of oxygen. As the President of the Alpine Club, Professor J. N. Collie, F.R.S., has pointed out, in those accustomed to high altitudes this suffices to support life, but the human engine obviously cannot do much work with so limited a supply of oxygen. The body, however, makes efforts to adapt itself to high altitudes, chiefly by a rapid increase in the number of red blood corpuscles. People living on the Pamirs—the extensive plateau known as “The Roof of the World,” from which diverge the principal mountain chains of Asia—have an average count of over 8 million red cells per cubic millimetre. Trained mountaineers have proved their ability to live and at the same time do a certain amount of work at an altitude of nearly 25,000 feet, and Professor Collie believes that the extra 4,000 feet necessary to climb Everest should not prove entirely prohibitive. The main objects of the survey party will be to reconnoitre the northern slopes of Mount Everest, with a view to finding a possible way up the peak itself, and to establish an advanced base for the party that later essays the final ascent. The leader of the present expedition is Lieutenant Colonel Howard Bury. The mountaineering party consists of Mr. H. Raeburn, with Messrs. G. Mallory and Bullock, members of the Alpine Club. The medical officer and naturalist is Dr. A. F. R. Wollaston; the chemist is Dr. A. M. Kellas, lecturer on chemistry in the Middlesex

Hospital Medical School; and two members of the Indian Survey—Major Morshead and Captain Wheeler—are attached to the expedition. The survey party propose to leave Darjeeling on May 14th, travelling towards Tibet through the Chumbi Valley.

EPIDEMIC HICCOUGH AND ENCEPHALITIS LETHARGICA.

A CONTRIBUTION of considerable value in regard to the association of epidemic hiccough with encephalitis lethargica was made by Dr. William Boyd, professor of pathology in the university of Manitoba, Winnipeg, in two papers published last year.¹ Encephalitis lethargica reached Winnipeg in the last week of October, 1919, and gave rise to a somewhat extensive epidemic. Of the 75 cases with which Dr. Boyd had personal acquaintance 29 died, and complete necropsies were made by him in 19 cases; in two other fatal cases, in which a complete examination could not be made, the kidney was removed for pathological examination. Professor Boyd gives a careful and well illustrated summary of the history, symptomatology, and pathology of the disease, and comes to the conclusion that the relation of encephalitis to influenza is more apparent than real, as twelve months separated the outbreak of the former from the latter, and most of the patients who suffered from encephalitis had never had influenza; similarly, his opinion is that the condition is quite distinct from poliomyelitis. There was a most remarkable epidemic of persistent hiccough in Winnipeg and the neighbouring towns in the early part of November, 1919—at a time, Dr. Boyd states, when it had not been reported from any other cities, and a few days after the first cases of encephalitis had appeared in the city. A very large number of cases occurred. The patients included several doctors, one of whom kept hiccoughing continuously at intervals of about a minute for five days; the usual duration of an attack was from twenty-four to forty-eight hours. The condition yielded readily to a single injection of morphine. If the two epidemics bore no relation to each other, Dr. Boyd suggests that the coincidence is at any rate remarkable. The myoclonic contractions of the abdominal muscles observed in lethargic encephalitis and the contraction of the diaphragm in hiccough were very much alike. Could it be, he asks, that the virus of the disease might spare the brain in mild cases but irritate the cervical origin of the phrenic nerve?

RESEARCH DEFENCE.

THE Research Defence Society has done a great amount of useful work during the thirteen years of its existence. It is something of a reproach to the intelligence of the nation that it should have to exist at all, but unhappily the opponents of experimental medicine—and in that we would include physiology as well as pathology—are among the most active of those who seek to obstruct the advance of science. It is a national society of men and women united to promote national health and efficiency, to bring about a better understanding of the value of medical and surgical studies, and to expose the false statements made against them. Before the war it had about 5,000 members and associates; it has not so many now, and this is a pity, for all of us enjoy the benefits which result from the studies the Society exists to defend. It was founded in 1908. Among those present at the foundation meeting was the late Lord Moulton, though, as one of His Majesty's judges, he did not think it proper to become a member. In the last number (April) of a little quarterly journal the Society issues, we are reminded of the very valuable evidence Lord Moulton gave before the Royal Commission in July, 1907. In the course of his evidence, copies of which the Society can, we understand, still supply, Lord Moulton said: “The advance of science

¹ *The Canadian Medical Association Journal* (February, 1920) and *Annals of Medicine* (Vol. 1, No. 2, July, 1920).

takes the workers in science more and more beyond the ken of the ordinary public, and their work grows to be a little understood, and much misunderstood; and I have felt that the need would come for interpreters between those who are carrying on scientific research and the public in order to explain and justify their work." It is for this reason that the Society's motto is *Interpres Interpretum*. Men and women of science are interpreters of Nature, and therefore the society which popularizes their work is an interpreter of interpreters. The Society will arrange addresses and lantern lectures and is prepared to supply literature to applicants, but it wants more members. The subscription, which is only 6s. a year, to include the Society's publication, may be sent to the Secretary at 11, Chandos Street, London, W.1. The president of the Society is Lord Lamington, the chairman Viscount Knutsford, the vice-chairman Mr. Stephen Paget, F.R.C.S., long its honorary secretary; its present honorary secretary is Lady Horsley, its parliamentary honorary secretary Captain Walter E. Elliot, M.P., and its honorary treasurer Sir David Ferrier, F.R.S. The last copy of the Society's quarterly, *The Fight Against Disease*,¹ contains a series of notes on various subjects, including the recent work of Calmette on tuberculosis, described in the *BRITISH MEDICAL JOURNAL* of December 11th, 1920. The very smallness of the subscription stands in the Society's way; it seems too much trouble to get a postal order for 6s., but we hope many of our readers will take that trouble nevertheless.

THE DISCOVERER OF BRIGHT'S DISEASE.

THE first volume of the new series of the *Guy's Hospital Reports*, edited by Dr. A. F. Hurst, with assistance in the various special departments, has somewhat altered its outward aspect, and is now to appear quarterly; but its contents are as attractive as ever, and among them the first is appropriately that on "Richard Bright and the discovery of the disease bearing his name," by Sir William Hale-White,² who dutifully speaks of his hero as certainly among the first five or six geniuses in our profession. Historical memoirs and obituaries rightly form part of the subject matter of hospital reports, and in the past the *Guy's Reports* have been noticeable in this respect; it is therefore satisfactory to learn that Sir William Hale-White will supplement his present interesting article by one on "Bright's contributions to medicine apart from kidney disease," and that Dr. John Fawcett will write on "Addison and Addison's anemia." The life-history and pathological activities of Thomas Hodgkin should also find a similar biographer, for he did much, and yet is chiefly remembered on account of the late Sir Samuel Wilks's self-denying loyalty in calling what is now more commonly known as lymphadenoma, Hodgkin's disease. In addition to a marvellous ability for making accurate observations, Bright had the much rarer gift of correlating and synthesizing data; he was a pioneer in cerebral localization, and one of the earliest describers in this country of acute yellow atrophy of the liver, of malarial pigmentation of the brain, of pulmonary collapse in whooping-cough, and the mitral murmur in chorea. But the causal relation of kidney disease to albuminuria and dropsy will always stand out along with Laënnec's work on thoracic disease (on which Sir William Hale-White is also to contribute a memoir) as the outstanding discoveries in medicine in the early part of last century; Bright's conclusions were solidly based on extensive observations at Guy's Hospital, and were published in 1827, 1833, and 1836, the last paper being entitled "A tabular view of the morbid" appearances in one hundred cases of albuminous

mine." Sir William Hale-White describes this series of papers as one of the most wonderful in medical literature, and points out that except for actual changes and blood pressure estimations every ordinary clinical manifestation is mentioned; Bright did indeed refer to the occasional occurrence of impaired vision and a hard pulse. So careful and complete were his observations that comparatively little has been added since he proved that the renal change is the primary factor. It is, of course, true that the association of albuminuria with general dropsy had been previously established in 1806 by William Charles Wells, the author of the famous "Essay on Dew," who, while giving the credit for the detection of albuminuria to Cruickshank in 1798, believed that all the abdominal organs, including the kidneys, were inflamed. Dr. John Blackall of Exeter, in his "Observations on the Nature and Cure of Dropsies," elaborated Wells's observations on albuminuria, and appears to have suspected that the kidneys were affected; but though these physicians may have prepared the way for Bright's great discovery they in no way anticipated it.

LIGATIONS OF THE LEFT SUBCLAVIAN ARTERY.

THE twenty first volume of the *Johns Hopkins Hospital Reports* (fasciculus 1) is entirely devoted to an exhaustive and interesting analysis by Professor Halsted of ligatures of the first portion of the left subclavian artery. The total number of cases in which this difficult operation has been performed are few, only 21 in all being recorded in the literature. This is partly due to the fact that the older surgeons forswore the operation, declaring that it was "bad in principle" and "most unfortunate in practice." The first part of the subclavian is, on the left side, very deeply placed, and in the presence of an aneurysmal sac of any size the field of operation is so cramped that the surgeon needs an eagle's eye, a lion's heart, and a lady's hand, as Thomas Fuller said, to carry the undertaking to a successful conclusion. Professor Halsted's monograph opens with a delightful and characteristic quotation from Osler tracing the history of the surgery of aneurysm, and proceeds to the description of successful ligature for a huge subclavian aneurysm. How large this was, and how formidable was the task of tying the vessel, may be readily appreciated from some excellent photographs of the patient. Halsted resected the left sterno-clavicular joint and the left two-thirds of the manubrium. Later he had to sacrifice the first costal cartilage and the adjacent part of the sternum. "The arch of the aorta and its descending part were then clearly seen and the left auricle of the heart could be palpated with the finger. At length the left subclavian artery was identified lying close to the vertebral column. Two pieces of linen tape were threaded round the vessel and tied with force sufficient to close completely the lumen without crushing the vessel wall. Recovery was uneventful, and the aneurysmal sac shrank greatly. Two years later it was seen to be again increasing in size. Professor Halsted then excised the whole sac after resecting the middle of the clavicle. The success of this case is a just and fitting tribute to the distinguished operator, for he it was who, in 1892, performed the first successful ligature of the first part of the left subclavian. The paper is in many ways full of interest and of scholarship. It contains an instructive discussion of the value of simultaneous ligature of the vein when dealing with the vessels at the root of a limb and in the popliteal space. Professor Halsted pays homage to Sir George Makins on this question, and gives a full translation of the classic case of Von Oppel and Korotkov, which illuminates the subject in an inimitable manner. It would appear that the only British surgeons who have tied the first part of the left subclavian artery are Stonham, Sir William Banks, C. G. Browne, Newbolt, Sinclair White, and Sir Charles Ballance. It must be admitted that this is a very

² *Guy's Hospital Reports*, 1921, vol. lxxi (vol. I, fourth series), No. 1, pp. 1-59. Issued quarterly. London: Henry Frowde, Oxford University Press. Subscription, 2 guineas, post free for volume of four numbers; single number, 12s. 6d.

fair proportion for one country out of 21 recorded cases, but it is possible that others may have performed the operation without recording the fact in print.

THE OPTOPHONE.

Dr. ARCHIBALD BARR, Emeritus Professor of Engineering in the University of Glasgow, on April 6th demonstrated before the Royal Society of Arts the improved optophone, the instrument invented by Dr. Fournier d'Albe for enabling the blind to read ordinary print. This instrument was first shown in this country by the inventor in 1912, before the Optical Convention, but at that time the stage of its development was such that a blind person could by its use only distinguish bright lights. A year later, when it was exhibited to the British Association in Birmingham, it had been improved so that printed letters could be recognized. The war retarded further development, but since the war Dr. Barr, having the resources of the engineering firm of Messrs. Barr and Son behind him, has, with the co-operation of Dr. Fournier d'Albe, so perfected the mechanism of the invention that with its aid ordinary letter-press can be read by a blind person after comparatively little practice. The instrument depends for its action on the fact that the conductivity of electricity by metallic selenium is increased by light. Above an electric filament lamp revolves a disc with five rings of perforations around its circumference. The light flashing through the perforations in the disc is led by a series of lenses to two selenium detectors which are interposed in a circuit with a battery and a telephone, and the flashes of light are transformed by the selenium detectors into sounds in the telephone. When the amount of light is modified by the interposition of any object, the sound in the telephone is modified accordingly, and this happens when the figure of a black letter of the alphabet, moved across a slot, is reflected into the line of the light from the lamp. The notes which are given out differ with each letter, so that letters, and eventually words, can be recognized by their distinctive notes. Even the audience at Dr. Barr's demonstration was able, under his tuition, to recognize certain large capital letters in a few moments. A blind lady who had had, it was stated, only some thirty hours' practice, was able before the audience to take up a book, place it in position on the instrument, and after a little difficulty in finding where the print commenced, read out several lines quickly without any mistake. Such languages as Hebrew, Arabic, and Chinese, with their distinctive calligraphy, would be even easier to read in this way than Roman letters, and Dr. Fournier d'Albe, who was present at the demonstration, claimed that with its aid the literature of the whole world is opened to the blind.

HOSPITAL ALMONERS.

THE report of the Hospital Almoners' Council for 1920 shows the increasing value of the work undertaken by this organization. It is important that almoners should be carefully trained and should have special qualifications for the post, and it is to these matters that the Council mainly devotes its attention. The view is now generally held that an almoner's duty does not merely consist in checking abuse of the out-patient department of hospitals. This officer, who is usually a woman, should acquire a knowledge of the patient's home conditions for the use of the hospital staff, and should co-operate with other charitable agencies in order to aid in carrying out the prescribed treatment in the most thorough manner. She should have a complete knowledge of the municipal and State activities which may have an influence upon the health and social conditions of the patient, and should organize the "after-care" of patients on discharge from hospital. If an almoner is to carry out such important work properly a thorough training, both general and technical, is necessary, and this training the Council is

providing. It extends over two years; part of this time is spent in general instruction in economic social theory at the University of London and in practical work with the Charity Organization Society. The remainder of the period is spent under the direction of an almoner at a hospital training centre in gaining a knowledge of an almoner's duties not only in the hospital, but in health visiting, infant welfare centres, rescue homes, and tuberculosis clinics. Certificates are granted by the Council to almoners who have gone through the recognized training; the offices of the Council are at Denison House, 296, Vauxhall Bridge Road, S.W.

CALCUTTA SCHOOL OF TROPICAL MEDICINE.

AN appeal to the Government of Bengal for an annual grant has been made by the Calcutta School of Tropical Medicine and Hygiene and the Carmichael Hospital for Asiatic Diseases. The financial statement issued with the note shows that down to the end of February Rs.20,77,904 had been subscribed, and that out of this the buildings and equipment had been provided, and an endowment fund of Rs.3,55,000 created. The estimate of recurring annual expenditure amounts to Rs.5,20,228, leaving a balance of Rs.3,92,000, which the Government of Bengal is now asked to provide. The appeal points out that the scheme has two sides, research and teaching—both essential for fighting disease—and that it is the teaching side the Government of Bengal is especially invited to support. The buildings, erected and equipped with the funds raised by Sir Leonard Rogers, provide not only for research work, which is already in part endowed, but also for post-graduate teaching of tropical medicine and hygiene.

PHOTOGRAPHS OF CRETINS.

WHEN the British Medical Association met at Carlisle in 1896, Dr. W. Rushton Parker of Kendal exhibited photographs of over fifty cases of sporadic cretinism which he had succeeded in collecting from many sources. This collection of photographs—one of the largest yet made—has been presented by Dr. Parker to the Royal College of Surgeons of England, where it may be seen and studied by all interested in cretinism.

THE Earl of Onslow, formerly Parliamentary Secretary to the Ministry of Agriculture, has been appointed Parliamentary Secretary to the Ministry of Health, in succession to Viscount Astor, whose resignation on the ground of ill health was announced a month or two ago. Sir Alfred Mond, Minister of Health, has appointed Sir H. Kingsley Wood, M.P., to be his parliamentary private secretary.

WE regret to announce the death, on April 12th, of Dr. Henry Barnes, O.B.E., of Carlisle, who was President of the British Medical Association in 1896-97. We hope to publish a memoir in an early issue.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Public Health and Local Rating.

WITH the revival of the rights of private members to bring up subjects on a limited number of evenings, Colonel Bowles, on April 6th, moved for the appointment of a Select Committee to inquire into the incidence of local rating by public authorities. He argued that these bodies had grievances in the burdens put upon them. He quoted the recommendation of the Royal Commission of which Lord Balfour of Burleigh was chairman, in 1904, that asylums for pauper lunatics should be made a national service, and pointed out that since then expenses for National Insurance, for tuberculosis sanatoriums, provision for medical inspection of schools, asylum officers' superannuation, and the working of the Mental Deficiency Act and of the Venereal Diseases Act had severally, in part or wholly, been placed on local rates.

Sir Arthur Warren, seconding the motion, reminded the House that under the Tuberculosis Bill now before Parliament there was an estimate that additional services would cost £40,000, and of this half was to be provided from the rates.

Sir Alfred Mond, the new Minister of Health, in the course of his reply, recalled that the cost of the fresh work which had been imposed upon local authorities by health developments—in regard to tuberculosis, venereal disease, maternity and child welfare—did not amount to more than a 2½d. rate through the country. He did not wish to indicate that he felt that new services should be lightly thrust upon local authorities at the present time. On the contrary, he took this first opportunity of stating to the House that it was his firm intention to endeavour to avoid all unnecessary expenditure in the very difficult financial condition in which the country was placed. While, however, it was important not to incur unnecessary new expenditure, it was, he said, even more important to see that full value was got for old expenditure. The fact that money was being spent on a service was by no means necessarily evidence that the best result was being obtained. Large expenditure did not necessarily show great zeal, often better results could be got by careful administration. He intended to devote his attention strictly to this side of the work. In this connexion he referred to a request made to him to introduce fresh legislation for the superannuation of Government officials, which would have put an increased burden on the rates.

Major Prescott, interrupting, asked whether the Minister was not aware that the recommendations of the Departmental Committee would not involve any charge on the rates.

Sir Alfred Mond replied that he was informed that was not the case.

Major Prescott rejoined that the report recommended a contributory scheme, which would not involve any charge on the rates whatever.

Sir Alfred Mond said that any way a contributory scheme would mean a contribution from the State. As to the comparative burdens of rates, Sir Alfred asked the House to remember that since the Balfour of Burleigh report the rates had been relieved as regards police and education charges, and also as to road maintenance. To transform local authorities into mere agents for spending other taxpayers' money would throw upon them a great temptation to incur local popularity at the cost of other people. He had a case of that sort recently brought under his notice in connexion with the infant welfare centres. That temptation could only be guarded against if the responsibility for expenditure was brought directly home. Sir Alfred Mond concluded by asking the House to be satisfied that a strong Cabinet Committee had been appointed to go into the whole question of local administration with a view to some legislation next session.

Captain Elliot, taking up a sharp criticism by Mr. A. Hopkinson of the administration of the late Minister of Health, said it should be put on record that there had never before been such an improvement in the vital statistics of the country as there had been during the administration of Dr. Addison, who was entitled to the credit of that achievement.

The motion was defeated by only a single vote, despite the fact that the Government Whips told against it. The figures were. Ayes, 48, Noes, 49.

Dr. Addison.

None are better able to judge of the value of Dr. Addison's services during his period of office as Minister of Health than the medical members of Parliament. The following resolution was unanimously adopted at a meeting on April 11th:

That the medical members of the House of Commons express their appreciation of the services of the Right Hon. Dr. Addison, as Minister of Health, and of the excellent work he has done in the face of many difficulties. They wish to place on record their admiration for his zeal and devotion to duty, and his untiring work in the interests of public health.

Civil Service Estimates.

The estimates for Civil Services for the year ending March 31st, 1922, have been issued in a series of White Papers.

Ministry of Pensions.—For the Ministry of Pensions the total estimate is £111,556,656, which represents a net decrease of £11,678,334. The cost of the medical services amounts to £11,153,000, made up as follows: Salaries, wages and allowances

of medical staff, including fees to members of medical boards, medical referees, etc., £2,277,000—an increase of £451,000; travelling and incidental expenses of medical staffs, medical boards, etc., £51,000—an increase of £26,000, travelling and incidental expenses of disabled officers, nurses and men attending medical boards, etc., £590,000—an increase of £24,000; medical treatment of disabled officers, nurses and men who have left the service, £6,508,000—a decrease of £1,402,000; expenditure in connexion with the provision of artificial appliances for disabled officers, nurses and men, £200,000—an increase of £374,000. In the sum already mentioned for salaries, wages and allowance of medical staff appear among many others the following particulars: Director General of Medical Services £1,800, Deputy Director General £1,500, Principal Medical Officer, £1,300, Chief Commissioner of Medical Services £1,350. Sixteen principal medical officers (at £1,200), £20,000. Three hundred and nineteen medical officers (at salaries varying from £750 to £1,100), £287,900. Fees to medical board, medical referees part-time medical officers, etc., £1,450,000, as compared with £1,230,000 for the previous year. All the salaries and fees named above are inclusive.

Ministry of Health.—For the Ministry of Health the estimates show a total of £24,345,098, being a net decrease of £3,342,093; the sum allotted to part-time medical referee consultants is £40,000—a decrease of £20,000, and the sum allotted for medical referee service, fees for nurses, etc., is £31,850—a decrease of £2,000. The miscellaneous grants include: Maternity and child welfare, £1,100,000—an increase of £323,000; treatment of tuberculosis, £1,210,000—an increase of £510,000; treatment of venereal disease, £120,000—an increase of £137,000; grants for the welfare of the blind, £100,000—a decrease of £9,000; grants to voluntary hospitals in respect of spirit duty, £3,500. In the total figures already given of £1,959,076 for salaries, wages, etc., for the Ministry of Health the amount for the medical staff is relatively small. The principal figures are: Chief medical officer, £2,000; six senior medical officers (at salaries ranging from £1,200 to £1,400), £7,890; fifty medical officers (at salaries varying from £600 to £1,100), £39,457; four divisional medical officers, £6,400; thirty regional medical officers (at salaries varying from £1,600 to £1,400), £37,024. Other figures include the remuneration of part-time medical referees and consultants, £40,000 as against £60,000 last year.

Scottish Board of Health.—The estimate for the Scottish Board of Health amounts to £3,375,999, being a net decrease of £573,293. Salaries, wages, and allowances are put at £240,393—an increase of £65,765; part-time medical referee consultants at £9,400, an increase of £5,000, the miscellaneous grants include maternity and child welfare, £180,000—an increase of £105,000; treatment of tuberculosis, £400,000—an increase of £194,000; treatment of venereal disease, £56,000—a decrease of £500; welfare of the blind, £20,000—an increase of £1,500; grants to voluntary hospitals in respect to duty on spirits, £650—a decrease of £100, Highlands and Islands (Medical Services) grant (grant in aid), £42,000. In the total figures already given for salaries for the Scottish Board of Health there are three entries for the cost of the medical department. Nine medical officers (at salaries from £500 to £800), £6,204; two medical referees (at salaries from £1,000 rising to £1,400 inclusive), and three medical referees (at salaries from £1,000 rising to £1,200), the five making a total cost of £5,400. The part-time medical referee consultants, etc., will cost £9,400, of which £3,250 will go in fees to local part-time referees and £4,000 in allowances for specialists.

National Insurance, Ireland.—The Civil Service estimate under this heading is for £618,785, or a net increase of £87,215 on the estimate for the previous year. Salaries include those of two medical officers at £700 a year, and one assistant medical officer at £350—these being unchanged. The main enlargement of expense is for grants in aid of sickness, disablement, and maternity benefit £230,600, and additional benefits £23,000, the two sums standing against £189,800, the amount of the estimate for the previous year.

Board of Education.—The total estimate for the medical department of the Board of Education is £17,441, as compared with £16,373 for the previous year. The present holder of the position of Chief Medical Officer, being also Principal Medical Officer of the Ministry of Health (in which capacity he receives a salary of £2,000 a year), has from the Board of Education only £100 a year. The total staff otherwise is nineteen, comprehending a chief medical inspector, a medical staff officer, six medical officers, and eleven inspectors.

Grants to Universities and Colleges.—The estimates of grants to universities and colleges of the United Kingdom is for a total sum of £1,416,000, which, with additional grants of £84,000 to the Irish universities, will bring up the total to be paid for the maintenance of university institutions in the United Kingdom to a million and a half sterling. This is in accordance with a pledge given last October by the Chancellor of the Exchequer, and represents an increase of half a million. The figures for England embrace allowances in respect of clinical units at four hospital medical schools in London. The grant to the London Hospital Medical School will thus be £13,000, as against £6,000 in the previous year; that to St. Bartholomew's Hospital Medical School £12,000, as against £5,000; that to St. Thomas's Hospital Medical School £10,030, as against £4,500; and that to University College Hospital Medical School £10,500, as against £4,000. The Universities of Oxford and Cambridge are each to receive £30,000.

The Parliamentary Medical Committee.

At the meeting of the medical members of the House of Commons on April 11th the Public Health Officers (Security of Tenure) Bill was discussed, and the Committee decided to lend it their support. The Coroners Bill was considered, and it was decided that when this bill reached Committee a new clause should be moved to increase the fees paid for *post-mortem* examination and medical evidence. The Dogs Bill was discussed, and it was agreed unanimously to oppose it. The Tuberculosis Bill and the Health Estimates were also considered.

Termination of the War.—In reply to questions on April 4th by Mr. Lyle-Samuel, Lieutenant Commander Kenworthy, and Sir Frederick Banbury, the Prime Minister explained the position as to the statutory termination of the war. The Act of 1918 provides that the date shall be as nearly as possible the date of the deposit of ratifications of the last Treaty of Peace. Mr. Lloyd George reckons that there must be some settlement at an early date between Turkey and Greece and all the other Powers, but also acknowledges that the matter of ratification cannot be left open indefinitely. The Turkish delegates have promised on their return to place the terms offered before the Assembly and to reply to the Allies within five or six weeks. That leaves another three or four weeks before the Turkish position is known.

Local Government Officers' Superannuation.—Sir Alfred Mond (Minister of Health), replying to Mr. Arthur Henderson on April 5th, repeated what Dr. Addison said some time ago, that no legislation on the subject of the superannuation of local government officers can be introduced this session owing to the expense that would be involved.

Public Health (Officers) Bill.—The first reading was given on April 11th to a private member's bill, introduced by Sir Philip Magnus, supported by Sir Henry Craik, Lieut.-Colonel Raw, Sir James Kennan, and Mr. Myers, "to amend the law relating to tenure of office of medical officers of health, sanitary inspectors, and inspectors of nuisances."

County Councils and Tuberculosis Treatment.—In reply to Mr. T. Thomson, Sir Alfred Mond stated, on April 11th, that 143 of the 145 county and county borough councils in England and Wales have made arrangements for the institutional treatment of non-insured tuberculous persons, but in one case the provision so far made extends only to dispensary treatment. The schemes of twenty-seven county and borough councils for the appointment of committees for the after-care of insured and non-insured tuberculous persons in their areas have been approved by the Ministry of Health or its predecessors.

Definitions in Lunacy Acts.—Captain Bowyer asked, on April 6th, whether the Minister of Health would amend the wording of the Lunacy Acts in order to substitute the terms "patients" and "mental hospital" for "pauper lunatic" and "pauper lunatic asylum." Sir Alfred Mond replied that he had nothing to add to the answer given by his predecessor to a similar question.

Pensions Grant for Heart Disease.—Mr. Raper asked, on April 7th, if the sum of £46,000 had been saved in pensions and grants to discharged soldiers suffering from heart disease; and what was the nature of the medical discovery by means of which this saving was effected. Mr. Macpherson said he had no knowledge of the figure referred to. A sum of nearly £4,000,000 a year was at present being paid to men who were pensioned for heart disease. Every effort was being made by the establishment of cardiological clinics with improved methods of diagnosis and treatment to restore the health of men who suffered from this complaint.

Approved Societies and Hospitals.—Colonel Milnamy asked the Minister of Health, on April 6th, whether he was taking any action in accordance with the recommendations of the interim report of Lord Cave's Committee with reference to the disposal, in the interests of hospitals, of the surpluses of approved societies. Sir Alfred Mond replied that a copy of the report had been sent to every approved society with a covering letter, in which the society was urged to give its serious consideration to the question of using part of its disposable surplus (if any) in making payments towards the cost of its patients in hospitals. This was only one of many additional benefits which it was open to societies to provide.

Pensions' Medical Treatment for Tropical Diseases.—Mr. Macpherson, answering Mr. W. Graham on April 7th, said that the Ministry of Pensions made no provision for the medical treatment of men disabled in former wars, and only in exceptional cases would a man need treatment now for a disability incurred so long ago; the question had, however, recently been raised in connexion with certain tropical diseases and was now under consideration.

The Naval Hospital at Yokohama.—In reply to Commander Bellairs, who asked whether the Admiralty could take steps to abolish the Royal Naval Hospital at Yokohama, Mr. Amery said, on April 6th, that the institution was required to receive convalescent cases from Hong Kong during the period of hot and damp weather experienced there. Its abolition would result in a larger number of cases being invalided home from the China station, with consequent inconvenience and expense. Commander Bellairs asked whether the Minister was aware that, although the hospital had some 80 or 90 beds, not a single patient was accommodated during the year 1920, and the

maximum was only 8 in recent years. Mr. Amery said he understood that last year the hospital was not open at the time that the patients from Hong Kong were usually sent, but he would inquire further into the matter and see if any economy could be effected.

Unsweetened Condensed Milk.—Mr. Doyle asked the President of the Board of Trade, on April 7th, whether he was aware of the proposed standard for unsweetened condensed milk being about 12½ per cent. below the minimum cream contents recommended by the great weight of evidence heard by the Committee appointed by the Minister of Health; whether this was against trade interests in this country—the standards proposed by the condensed milk industry, manufacturers, importers, and the trade in this country were based upon the description officially given to this article in the Public Chemists' Report for many years; and whether he would use his influence with the Minister of Health to fix a reasonable standard which could be met by producers in this country, and which importers should be required to reach if they desired to trade here. Sir P. Lloyd Graeme said he was aware that the proposed standard was lower than was recommended by English makers, but he could not accept the various suggestions made by Mr. Doyle. In determining the standard, consideration had to be given, not only to the interest of British manufacturers, but to those of other sections of the trade, and still more to the necessity of maintaining at competitive prices adequate supplies for the requirements of this country.

The Coroners' Remuneration Bill was read a second time on April 6th.

With the dissolution of the Ministry of Food the powers and duties of Food Controller as regards the output of intoxicating liquor were transferred to the Board of Trade. The Government are considering whether any, and if so what, restrictions on the quantity of beer should be maintained.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society, Limited, was held at 32, Craven Street, London, W.C., on April 6th. Sir JOHN ROSE BRADFORD, the President, was in the chair, and in moving the adoption of the annual report of the council he referred to the society's continued prosperity. During the year 733 new members had been elected, a net gain of nearly 500, bringing the membership up to well over 6,000. Almost alone amongst societies, this body had not found it necessary to raise the annual subscription above pre-war level. A great depreciation had to be recorded in the value of the securities held, but, inasmuch as these were—value of the securities held, but, inasmuch as these were—at least it was hoped—a permanent investment, the fact of depreciation was not so formidable as might appear. The credit balance on the actual working of the society during the year amounted to £1,755. He added that the results of lawsuits had been in the main favourable, but many cases had been satisfactorily settled out of court. The changing conditions of medical and dental practice had given rise to new dangers and difficulties, which meant increased work for the society in time to come.

Dr. C. M. FEGEN, the treasurer and chairman of council, said that the invested funds of the society amounted to some £30,000, which meant that if the society went into voluntary liquidation—a thing it had no intention of doing—every member would be entitled to take out £5, the equivalent of five years' subscription.

Dr. C. O. HAWTHORNE, while praising the report in general, criticized an item of 15 guineas which had been paid as subscription to the Federation of Medical and Allied Societies. He submitted that the subscription paid by members to their society was for a very narrow and specific purpose, which did not include medical and politics. He moved an amendment asking the council to reconsider its decision. Sir JOHN ROSE BRADFORD said in reply that the matter had been considered very fully by the council, which had proceeded under an article definitely empowering it to take such action. Dr. FEGEN also defended the action of the council. Politics, he said, were entirely absent from its deliberations, and the action was taken because it was believed that the Federation could speak for a large number, if not the greater number, of members of the medical profession. The appointment of representatives to the Federation did not necessarily mean that the society endorsed the Federation's policy. The report of the council was then adopted.

Sir John Rose Bradford was re-elected president by acclamation. The vice-presidents, retiring members of council, the treasurer, and the general and financial secretaries (Dr. Hugh Woods and Mr. A. G. R. Foulerton) were all re-elected, with expressions of appreciation for their past services.

EIGHTY-NINTH ANNUAL MEETING of the British Medical Association, NEWCASTLE-UPON-TYNE, 1921.

LOCAL INDUSTRIES.

COAL MINING.

NORTHUMBRIA and Durham have long been known as the mining district of the North, and Newcastle-upon-Tyne and Coal are inseparably associated. There is evidence that the existence of coal in the district was known to the Romans, and that they used it for domestic purposes, but coal mining as an industry probably dates from the reign of Henry III. This monarch "by his letters patents . . . thought it fit to give them licence to dig coals . . . and to draw and convert them to their own profit . . ." The industry has steadily developed from that time onwards, and has long been the mainstay of the north east coast, for, as always happens when coal is plentiful, manufacturers of every kind sprang up and ever expanded in the district. A good idea of the extent of the industry can be gathered from a few facts concerning the Ashington group of collieries, the most important in the district and one of the largest in the world.

Our second illustration is of Ellington Colliery, one of the group, and typical of the very many collieries scattered about the Northumberland coalfield. There are seven shafts in this group, varying in depth from about 35 to 90 fathoms, and an average of about 9,000 tons of coal come to the surface each day. The work employs over 9,000 men and boys, and the collieries support a local population of about 30,000 people.

Much of the labour of "coal getting" is still done by hand with the pickaxe, aided by the use of explosives, but coal cutting machines of various types, either driven electrically or by compressed air, are coming more and more into use. For bringing the coal from the workings to the shaft ponies and horses are still largely used, and at Ashington nearly 1,300 of these useful animals are employed. Accidents in coal mining are most often due to falls of stone and to prevent this the roof is supported by timbering. It gives a good idea of the amount of work underground to mention that over 15,000 pieces of timber are used on an average every day.

The ancillary works connected with these collieries are enormous, and include a power plant with an aggregate of forty seven Lancashire boilers and an electric plant generating current of 5,350 horse power. Screening the coal is an important process conducted at the bank by

mechanical means, but employing large numbers of boys and older men. The upkeep of the collieries requires staffs of workmen, such as masons, joiners, engineers, and officials of all kinds, while the transit of the coal from the pits calls for the use of extensive railways and rolling stock. A small proportion of the coal is used for domestic purposes, much is exported, but most is employed in local manufactures.

Some of the coalfields in this district have been fully developed and the best seams exhausted, but the advent of mechanical methods and of electricity have rendered it possible to utilize the smaller seams. Coal from this district in the form of coke is the principal fuel used for smelting the ironstone of the North Riding of Yorkshire. It was found that the type of coal was too soft and wasteful to use in its new state for blast furnaces. For years the coking process was carried out by beehive ovens, when any benefit from the waste heat and gases was lost. Means were devised by which the waste heat could be used for boilers, and this was followed by special by-product ovens of various types, which were designed for the separation of gas, benzol, tar, and ammonia. These processes have greatly increased the value of the industry, so that the by-products are now as important as the coke itself. In 1913 the two counties of Northumberland and Durham produced fifty six million tons of coal, which constitutes a fifth of the total output of the United Kingdom.

Iron and Steel.

The iron and steel industry of this district is also known to have had its origin in Roman times. The ore was probably smelted by the aid of bellows made of bullocks' skins, and large masses of partly melted ore have been found, notably in 1909, at Corstopitum, near Corbridge. There are reasons for assigning to this collection a date approximating to A.D. 350-380. Relatively very little progress was made in the manufacture of iron until 1735, when Abraham Darby succeeded in bringing to the notice of the ironmasters the enormous advantages of coke. From this time onwards we find the County of Durham assuming an important position among British iron producers on account of the fact that the Durham coals are exceptionally well adapted to the production of coke of the best quality. At the present date there are numerous blast furnaces and rolling mills all

Ellington Colliery, typical of the Northumberland Coalfield. (Block kindly lent by Ashington Coal Co., Ltd.)

over Durham and a few in Northumberland, the ore being mostly obtained from abroad or from the Cleveland district of Yorkshire. These two northern counties yielded about one-seventh of the total British open-hearth steel output in 1913. There are two firms on Tyne-side that regularly work electric furnaces, whilst two others smelt electrically some of the ferro-alloys employed in the manufacture of high-speed tool steel and other special steels of the highest class.

Ship-building and Marine Engineering.

Another of the great industries is that of ship-building. As far back as 1642 Newcastle was known as the nursery for shipping, and many of the "hearts of oak" that beat the seas in those days were cradled at the Tyne yards. By the nineteenth century, with the introduction of iron for hulls, ship-building rose to a position of still higher importance in the industry because of its inexhaustible wealth of iron and coal. The first iron ship to be built on the Tyne was the *Prince Albert*, launched in 1842 from Coutt's yard, now part of the extensive works of Swan Hunter and Wigham Richardson, Ltd. In 1844 Palmer's, of Jarrow, brought out the water tank system for ballast in place of the old system of sand and chalk, and since that day the characteristic "ballast-hills" of Tyneside have steadily disappeared. The development of armoured warships was largely due to the initiative of the Tyne ship-builders. This led to the construction, in 1856, of H.M.S. *Terror*, the first armoured ship in the world. The modern cruiser owes its existence to the first Lord Armstrong, of Elswick Works (see illustration, page 577). The first ship of this type was built there in 1884.

Of the naval works on the Tyne, special mention should be made of Armstrong's and Palmer's works. In 1897 Sir Charles Parsons introduced the steam turbine for marine purposes, and it is now used in many forms of ship.

The list of warships built on the Tyne propelled by steam engines is a very long one, and to the various types already mentioned may be added destroyers, submarines, and monitors of several different designs. In recent years oil has to a large extent superseded coal as fuel.

The construction of merchant ships has for long made the north-east coast famous. Some builders have specialized in general cargo boats, whilst others have won fame by building passenger ships and boats for special purposes, such as colliers, trawlers, oil tankers, and other types. The best known passenger and mail steamship of recent years is the Cunard Company's express mail steamship *Mauretania*, built in 1907 by Swan, Hunter, and Wigham Richardson's, and a sister ship to the ill-fated *Lusitania*. Parsons's steam turbines drive her four propellers, and it is a tribute to Sir Charles Parsons's genius that in less than ten years after the appearance of his little ship, the *Turbinia*, it was decided to install turbines of his design in ships which at the time surpassed all others in size.

In conjunction with ship-building, ship repairing has

always been an important industry on the north-east coast. Many notable cases of ship surgery have been successfully taken in hand. Floating docks of all sizes have been constructed and exported to all parts of the world. The general equipment of the shipyards on the Tyne is well abreast of the time, and the enormous floating and stationary cranes are famous the world over. The

The County

tonnage launched from the Tyne and the Wear for twenty years previous to 1914 was rather more than half the total of the United Kingdom.

Marine engineering is also an important industry on the Tyne. This is essentially a modern development, its entire history dating from not more than 100 years ago, but it is of paramount importance where shipbuilding is concerned.

Other Industries.

Electrical industries are also well to the fore: it was on the Tyne in 1879 that the incandescent lamp was produced in a practical form. During the century perhaps the most remarkable industrial development in the district has been the production of electricity on a large scale, both for lighting and as a means of power. In many of the collieries and shipyards it has taken the place of steam, and is becoming more used every year. For considerably more than a century the manufacture of lead has been an important industry in Newcastle, lead ore being extensively mined in Tynedale, Allendale, and Alston, and smelted in the neighbourhood. The local production of the ore now is far from sufficient for the requirements of the lead manufacturers, who import the greater part of their supplies from Spain, Greece, Mexico, and Australia. Quarrying is a very minor industry. The product is limestone, mostly used as a flux in blast furnaces; rather more than three million tons were produced in the two counties in 1913.

Agriculture in Northumberland.

But though the Tyne and its banks together with the south-eastern corner of the county represent a mining and manufacturing district known the world over, the greater part of Northumberland is agricultural. Arable farming, dairy farming, and sheep rearing are each extensively practised, the latter especially among the sequestered hills and valleys of the Cheviot Range:

Where the curlew screams in its wild retreat,
And the fleet hare bounds from its lowly seat;
Where the moor fowl crouch on the heather bed,
And the restless plover wails overhead.

The importance attached to agriculture is reflected at the Cockerle Park Experimental Station, where most valuable research work has been carried on since 1896. The tower at Cockerle Park Farm (shown in the third illustration) is a reminder of the troublous times when the farmhouses were fortified against the attacks of the dwellers in the "debatable land."

England and Wales.

THE FUTURE OF BRISTOL UNIVERSITY.

At a luncheon which took place at the Royal Hotel, Bristol, on April 7th, Sir Isambard Owen, M.D., Vice-Chancellor, made a speech on the future of the University of Bristol. He asked why the communities of the South-West should not re-establish their former position of leadership in the new era of progress. The important question for industry was, How long would the empire of coal over industry last? It was already threatened by oil, and geologists and chemists were endeavouring to find other substitutes. All round the coast of the West of England were reservoirs of power that needed only to be harnessed to be placed at the disposal of man. A proposal to that end was under consideration, and, if carried out, it would cause a great alteration in existing conditions. The West of England was ready for whatever might happen. A great service had been rendered by the establishment of technical colleges and the advantage of technical knowledge had been proved in recent years.

Having given a description of some of the features of the university buildings, Sir Isambard Owen said that unfortunately the cost of the new developments had increased enormously since the war. Only one-third of the cost of maintenance could be covered by the fees. The Government was doing what it could to add to the resources; the Corporation of Bristol had nearly doubled its grant, whilst the committees of Gloucester and Somerset and the cities

of Bath and Gloucester had undertaken to contribute. The time had come when Bristol University must complete its equipment and make ample provision for its future working. If the universities of England were to preserve their freedom of action, the means must be supplied. A university dependent upon the Government was not free, and when a university lost its sense of freedom it lost in its usefulness, and its output of original work was lessened. Hence an appeal was being made to the public of the entire district that Bristol University was designed to serve.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The annual meeting of the President and General Council of King Edward's Hospital Fund for London, to receive the accounts and the report for 1920, was held at St. James's Palace on April 12th, with H.R.H. the Prince of Wales in the chair. The total receipts for the year were £480,431, of which £255,365 was the sum received from the Joint Committee of the British Red Cross Society and Order of St. John of Jerusalem. The amount distributed was £700,000; of this the distribution of surplus Red Cross funds in aid of schemes of extension and improvement accounted for £250,000, the emergency distribution £250,000, and the ordinary distribution £200,000. The amount of the emergency distribution was taken from reserve funds held in cash or short-dated securities, as also was the sum needed to maintain the ordinary distribution at its previous figure. The effect of this was to reduce the reserves by about one-fourth, and the income from invested funds by about £16,000. The Council made this sacrifice in the hope that, with the aid of others interested, time might by this means be secured for the reorganization of hospital finances. They consider, however, that any repetition of such a drain on the invested funds and on permanent income would be disastrous to the Fund and to the hospitals. The Council pay a warm tribute to Sir John Tweedy, F.R.C.S., on his retirement from the chairmanship of the Distribution Committee, in which post he has been succeeded by Sir Cooper Perry, M.D. The problem of hospital finance was continuously before the Finance Committee of the Fund throughout the year, and the report ends by calling upon all who believe in the voluntary system to make a special effort to support the hospitals during the present crisis, and to ensure that voluntary contributions form at least a substantial part of their income in the future. The Prince of Wales in his short address voiced the general feeling of the Council when he said: "I think we are all very glad that Lord Cave's committee have reported so decidedly in favour of the voluntary system of hospital management."

THE GREAT NORTHERN HOSPITAL.

The Committee of Management of the Great Northern Central Hospital, Holloway, having considered a report of the Conference on National Health convened by the Faculty of Insurance, has expressed the following opinion for transmission to the British Hospitals Association and the press:

- (a) Insured persons treated both as in- and out-patients should be paid for in full by approved societies.
- (b) Payment should be made to the hospitals by the societies concerned by means of capitation grants, and not by the handing over of lump sums.
- (c) In view of the general public's limited opportunities of gaining knowledge of voluntary hospital questions, an effort should be made to form a Volunteer Hospitals Publicity and Propaganda Committee, towards the funds of which all hospitals should be invited to subscribe according to their number of beds and out-patients.
- (d) Such a Committee should consist of hospital representatives with some of the best publicity experts. It should endeavour to promote the interests of voluntary hospitals generally, and leave it to individual institutions to make known their particular needs.

ANTHRAX IN SHAVING BRUSHES.

Dr. William J. Howarth, Medical Officer of Health for the City of London, in his last monthly report refers to the circular letter by the Ministry of Health indicating the action to be taken in connexion with cases of anthrax attributed to the use of infected shaving brushes, an account of which was given in the BRISTOL MEDICAL JOURNAL of February 5th, 1921, p. 207. A method of partial disinfection of all brushes was described in the

circular, but, as Dr. Howarth points out, complete sterilization of the brushes is impracticable, and while the formalin method may be relied upon to free the exposed part of the hair from infection, it does not affect spores embedded in the handle of the brush. He records that in the City of London he received every assistance from the various city traders who had been affected by the discovery of anthrax in Japanese shaving brushes. They all, without exception, readily complied with any suggestions made by him, and many of them voluntarily asked him to undertake the destruction of their stock of suspected brushes rather than incur the risk that would attach to their sale. A table is given in the report showing the numbers of each pattern of brush that had been destroyed up to March 12th, 1921. In all, 13,224 brushes were destroyed, and one box of bristles. In each case a certificate of destruction was issued to the owners.

Scotland.

CONFERENCE OF SCHOOL MEDICAL OFFICERS.

THE Association of School Medical Officers of Scotland held a conference in Edinburgh on April 7th and 8th, with Dr. A. E. Kidd as president. At the opening session Dr. John Macpherson said that it was an extraordinary thing how little attention had been directed to the great promise for the future that the medical examination of school children held out. Apart from its remedial and preventive functions, it should eventually introduce a general survey of the population whereby the utility of each citizen would be known and placed at the service of the State. Defects which the recruiting for the army had shown up might have been avoided if the system had been in existence thirty years ago. Dr. F. G. Shrubbsall, medical officer of the London County Council, spoke on the subject of men of deficiency. He pointed out that the individual must be treated as a whole, and that it was not sufficient to say because a boy failed to pass nine out of ten tests that he was defective; it depended on a study of the history, the physical examination, and the clinical examination of the individual. Family history also was of importance, but it must not be overweighted. In mental testing it was usual to assess general intelligence by one or other of the graduated series of tests, but it was important that these tests should not lay too much stress on verbal imagery. In assessing the individual the certifying officer ought to feel sure that with a similar upbringing and in similar conditions he himself would have acted differently.

At the second session, which was presided over by Professor A. Darroch, chairman of the Edinburgh Education Authority, Dr. Norman Walker spoke on skin diseases in school. He said that pride of place among skin diseases in schools must be given to scabies. In every war scabies had been one of the chief causes of incapacity, and after every war the facts regarding it had been carefully collected, carefully printed in reports, carefully bound—and carefully put away. If a tenth of the skill that was put into tracing small-pox contacts were devoted to scabies it could very soon be absolutely stamped out. A more difficult problem was that of ringworm. It would be of enormous value in the campaign for the removal of that disease to know the actual number of children who were absent from school on a given day on account of ringworm. In the towns it would be found to be a number which would be rather surprising. At the afternoon session, with Dr. J. Mattie in the chair, Dr. Angus MacGillivray, reader in Ophthalmology at St. Andrews University, spoke on "The educationally blind child." He said that the rational treatment of short sight should be based on an accurate knowledge of the causes of the condition, such as holding a book too near the eyes and stooping over the work, especially in bad light and bad hygienic conditions. Proper posture while at work should, therefore, be insisted upon. The children at the Myope School were educated without any books, the teacher at the blackboard being the book. The chief feature of the teaching at the Blind School was that the pupils were taught to do their work sitting erect, stooping being prohibited, and after a few weeks the child was quite

independent of his eyes for near work, learning to read his Braille type by touch.

On the following day the conference was resumed by a lecture by Professor Georges Dreyer of Oxford University, on "The assessment of physical fitness," with Sir Leslie Mackenzie, of the Scottish Board of Health, which had arranged the lecture, in the chair. Professor Dreyer said that those who were concerned with the question of physical fitness were often faced with the difficulty of making up their minds definitely whether they were face to face with people who were of a lower kind of physique than they should be. In the past investigators had had to rely largely on their impressions, helped by certain measurements. Most of the existing tables dealing with the size of the normal human body were based on the theory that definite relationships existed between the age, height, and weight of the individual. His own conclusions were that there was no definite relationship between age, height, and weight which could compare in accuracy with the relationship which did definitely exist between weight, trunk length, and the circumference of the chest—relationships which were unaffected within wide limits by age, Recreation, occupation, and disease affected very considerably the development of the legs, so that the height was an uncertain and unsatisfactory measure to use in relation to weight. After the lecture a demonstration of the apparatus and methods of measurement was given by Dr. F. G. Hobson of Oxford University. At the afternoon session, which took the form of a joint meeting with the Scottish League of Organizers and Teachers of Physical Training, the subject of discussion was "Physical education," Mr. James Malloch being in the chair. The discussion was led by Dr. Alister Mackenzie, Principal of the Dumfries Training College, who appealed for co-operation between the physical training expert and the school medical officer.

GYNAECOLOGY AT THE EDINBURGH ROYAL INFIRMARY.

At a meeting of the managers of the Edinburgh Royal Infirmary, on April 4th, reference was made to the expiration of Dr. A. H. Freeland Barbour's term of service as gynaecologist to the Royal Infirmary. The managers placed on record their recognition of the skill and attention he had brought to bear on the duties of his office during the thirty-five years of his connexion with the department, and of the sympathy and tender care patients had received at his hands. In consideration of his valuable services he was unanimously appointed consulting gynaecologist to the institution. At the same meeting regret was expressed at the loss of the services of Dr. N. T. Brewis, who was appointed assistant physician in 1901, and in 1906 took charge of one of the gynaecological wards. The managers placed on record their sense of his eminence as a clinician, which, along with his sympathetic manner, not only endeared him to his patients and colleagues, but secured for him the esteem of the profession generally. It was agreed to ask him to accept the post of consulting gynaecologist.

HOUSING IN SCOTLAND.

The annual Scottish National Housing and Town Planning Congress will take place in the City Chambers, Edinburgh, on April 19th and 20th, with Sir Henry Ballantyne, Chairman of the Royal Commission on Housing in Scotland, in the chair. The Congress will be attended by representatives of county councils, town councils, architectural and technical associations, and associations of employers and workers, and will consider various housing and town-planning questions, more especially those of an urgent character, such as the need for the adherence of the Government to the programme for which legislative provision was made by the various Acts of 1919. The fixing of rents, housing finance, the management of housing estates, standards of construction and design, and the preparation of schemes for carrying into effect the recommendations of the Royal Commission on Housing in Scotland, will also be under the consideration of this Congress.

PROFESSOR LUIGI CAROZZI, medical inspector of industry and labour in Italy, has been nominated head of the Service of Hygiene at the International Bureau of Labour in Geneva.

Correspondence.

THE SCIENCE OF ETIOLOGY, OR THE NEW EPIDEMIOLOGY.

SIR,—Your "distinguished bacteriologist" says that the method of the newer epidemiology, "instead of accumulating facts in laborious fashion, aims at a solution of the problem by postulating causes, and apparently by eliminating the principle of specificity."

What "new" epidemiologists renounce the laborious accumulation of facts? Is it Dr. Brownlee, whose conclusions are based upon many years of clinical experience as well as upon the statistical records of generations? Is the Medical Officer of the County of London really an epidemiological Lady of Shalott isolating herself from the laboriously accumulated facts of disease?

Because there is a whole group of etiological momenta common to the enteric group of diseases, another group common to the venereal diseases, many epidemiological affinities between scarlet fever and diphtheria, and so forth, and because epidemiologists, whether "new" or old, subject these factors to statistical or historical examination, is there any sense in accusing them of eliminating the "principle of specificity"? One may recognize something without perpetually chattering about it.

If any "new" epidemiologist supposes that the whole problem of etiology can be solved by doing sums or by reading the collected works of Sydenham, he must be a very foolish man. If any bacteriologist thinks that the elimination of, say, epidemic disease of the typhoid group can be secured by immunizing the population first against *B. typhosus*, then against paratyphoid A, paratyphoid B, paratyphoid C, and so on to the end of the alphabet, all other things remaining constant, he must be rather naïf. I have not myself met an epidemiologist of the former or a bacteriologist of the latter class, and surmise that the names of such persons are John Doe and Richard Roe.

I do not believe that anything is gained by setting up these scarecrows; your distinguished correspondents can surely do something better than that.—I am, etc.,

Loughston, April 10th.

ALVOR GREENWOOD.

TRANSFIXION OF THE BODY.

SIR,—In your issue of April 9th Dr. S. D. Clippingdale has referred (p. 550), to the specimen of the gig shaft now preserved in the Museum of the Royal College of Surgeons, London, but with such lamentable surgical inaccuracy that I feel it incumbent to put the real facts of the case before your readers. I may cite, with omissions, from the account as given in the last edition of the *College Catalogue*, 1915, drawn up by Mr. C. F. Beadles and myself. Besides the gig shaft (No. 2241.2), which is perfectly entire, the Museum contains part of the anterior wall of the thorax (2216.2), through which the shaft was driven ten years before death. The shaft entered on the left side, between 3 in. and 4 in. from the sternum, was driven across the mediastinum, and passed out of the thorax about 3 in. from the right side of the sternum, between the second and third ribs; the tug iron of the shaft penetrated the chest and the lung rather lower down on the left side, between the third and fourth ribs. The patient, in the circumstances cited by Dr. Clippingdale, felt the end of the shaft perforate his side under the left arm, which was raised high up, and as the horse continued plunging he felt it pass from under his right arm. The patient's cries very shortly brought assistance, and the horse having been put back, he, with the aid of those who had come to him, drew himself off the shaft on which he was impaled. On the ninth day it was first thought prudent to move the patient sufficiently for completely undressing him and examining the wound; from this time he gradually recovered.

Placed immediately before this there is also in the College Museum (No. 2215.1) the pivot of a try-sail mast which passed completely through the body of a sailor, traversing the chest and upper part of the abdomen; complete recovery ensued. An excellent water-colour drawing of the patient made by Clift, the first conservator, is exhibited by its side; the drawing shows the healed entry and exit. The pivot, after passing obliquely through the body, penetrated the

deck. The mast was 39 ft. long and about 600 lb. in weight. The man was carried to the London Hospital, where, under the care of Mr. John Goldwyer Andrews, he recovered in five months so as to be able to walk. He ultimately returned to his duty as a seaman.—I am, etc.,

S. G. SHATTOCK, F.R.S., F.R.C.S.,
Pathological Curator, Royal College of Surgeons
of England.

April 13th, 1921.

ASTHMA AND ANAPHYLAXIS.

SIR,—In response to Dr. James Adam's letter of March 26th and other letters, for which I beg to thank the writers, commenting on my article of March 12th, I should like to make the following observations:

We may liken the solving of the asthma problem to doing a difficult jigsaw puzzle. The first thing to do is to display all the pieces, if none are missing; the second to fit them in to each other; we may then admire the completed picture. Now I only claim that anaphylaxis is an important "piece" and that it can be shown to fit many other pieces, but it is not the whole picture, nor do I think it any simplification to say, as Dr. Adam does, "The extreme sensitiveness displayed by these patients to minute doses of hundreds of substances, harmless to ordinary individuals, indicates an extraordinary unstable metabolism." I think it indicates anaphylaxis, or, at any rate, it is simpler to say so.

On the other hand, I know Dr. Adam's most excellent book almost by heart, and have been able to cure many patients simply by conforming rigorously to the early evening meal, the weekly starvation, and purge.

But again this is only a piece of the puzzle and not the whole picture; nevertheless it very nearly fits the anaphylactic pieces. In this late meal, overfeeding, week end, type of case, complete digestion and the breaking down of proteins to peptones and amino-acids is interfered with. The stomach is given more than it can deal with, or the starches, fats, and proteins may be so intimately mixed in the cooking that the proper digestive fluid and service for each is unable to reach them. Un-broken-down proteins may then pass through the intestinal wall, whence, unless stopped by the liver, they will enter the general circulation, initiate a "hémoclasique crisis" followed by an attack of asthma some hours later, that is, in the middle of the night.

Surely the essential condition in the lung is a spasm of the bronchiole muscle, which has been abundantly demonstrated in sensitized animals. The lungs of a sensitized animal are removed from the body and alternately expanded and deflated with an air pump, they are then perfused with a fluid to which the animal is sensitive; the bronchiole muscle at once shuts down and the typical picture of asthma occurs. I do not find the week-end type as common as Dr. Adam does, and there would be no difficulty in parading a dozen asthmatics who started their asthma during the war under those ideal conditions which one knows stopped not only asthma but migraines and many other of these chronic complaints.

Dr. Adam finds a flaw in the anaphylactic theory of asthma because of the periodicity of the asthmatic attacks, which periodicity is absent in anaphylaxis. My argument is that asthma is an anaphylactic phenomenon and will occur each time an exciting dose of the protein enters the patient who is sensitive to it, whether it be in the Christmas holidays every time the small boy empties a plate of nuts, or three times a week during the hunting season, or every week-end when Demos fills himself up to the neck. It is not a periodicity of the asthma but of the cause of this anaphylactic symptom.

I join most heartily with Dr. Adam in his call for research, for which asthma and these allied complaints offer an immense field. Who will tell us what the eosinophilia means? Or why, when I obtain a skin reaction to oats as big as a halfpenny, does the child not become covered with urticaria after a plate of porridge, but instead has an attack of asthma?

The inter-relationship of asthma or sensitization and tuberculosis is too complicated to touch on in a short letter, but extremely important. With regard to giving serums by the mouth, others are better qualified than I am to answer this. New French work suggests that mixture of sodium hyposulphite with the serum will obviate anaphylactic symptoms. I have not the paper by me, but will

send the reference to Dr. Allison. But in no case should horse serum be given to asthmatics—so many of them are sensitive to horse, so that the first dose is poisonous. Most of the deaths that have occurred after horse serum have been in these horse asthmatics.—I am, etc.,

London, W.2, April 11th.

FRANK COKE,

ADRENALINE IN RESUSCITATION.

SIR,—I have read the letter of Lieut.-Colonel Marjoribanks, in your issue of April 9th, in which he asks me one or two questions.

I agree with him that dilution of drugs with the blood can be secured to any extent, and that the rate of injection of an intravenous solution is quite as important as the strength of the solution.

There is one point, however, which he misses in relation to resuscitation. A person who has been drowned, or is in a state of what we may call temporary death, is necessarily a person whose circulation has stopped. Under such circumstances it is quite useless to inject any drug into the blood, as it cannot have any effect owing to the absence of circulation to carry it on to those parts of the body where it can act. Adrenaline acts upon the peripheral vessels of the circulation, chiefly upon the peripheral arterioles, and in order to get it there when we are using adrenaline for the purpose of resuscitating any body, it is necessary to temporarily establish an artificial circulation in order to carry the drug to the periphery. For this reason the intravenous infusion of saline solution, or gum solution, is necessary in a quantity of two pints, or even more. Adrenaline must, I think, be introduced in this solution in a dilution of about 1 in 50,000, or a small quantity of liquor adrenalini hyd. (B.P.) must be injected into the circulation while the infusion is in progress. It would, in my opinion, not be safe to give a 10-minim dose of adrenaline and follow this with the saline infusion, as too big a dose of adrenaline would reach the peripheral circulation at one time. For this reason I advocate the use in such cases of diluted adrenaline solution in the infusion fluid.

It is just here that the necessity comes in for a person skilled in adrenaline transfusion being present, as it is impossible, so far as I am aware, to lay down an exact rule with regard to the dose of adrenaline that will have to be administered. Infusion should be stopped as soon as the heart starts and the circulation is re-established, and then resumed in small quantities if the circulation slows further signs of failing. The action of adrenaline is violent, even in minute doses, and also very transitory, its effects disappearing in about two to three minutes.

I am afraid I cannot answer Colonel Marjoribanks's last question more accurately than to say that I believe that where the circulation has stopped it will be necessary to give an intravenous infusion of water, or better still salt solution, containing adrenaline in the dilution of about 1 in 50,000, up to from two to three pints, and that when this has been administered the heart will probably restart, either by itself, or with a very slight stimulus, such as the prick of a needle, or pressure from without through the chest wall.—I am, etc.,

J. P. LOCKHART-MUNMERY, F.R.C.S.

London, W., April 9th.

IRRITABLE BLADDER.

SIR,—The condition described by Dr. James Hamilton (March 26th, p. 480) seems to me to be especially dependent on the loss of normal contractility of the perineal portion of the urethra. This portion has the thinnest and most easily dilated walls, and in these cases it is always possible, after the bladder has been emptied, to squeeze from it a few drops of urine.

These patients are always told to empty the bladder and even to "milk" the prostate; the real object, however, should be to empty that part of the urethra thoroughly. If this is not done the small quantity of urine retained becomes, I believe, inspissated by absorption of its water, and so more irritant. The more irritant the urine in the first place, the more irritant is the inspissation, and hence one cause of occasional excess of irritability.

The emptying of this part of the urethra should be done by pressure with the fingers from the anus to the front of the perineum, repeated fifteen to twenty times after micturition, the anterior portion being also carefully

emptied until no further drop can be squeezed from the fossa navicularis. Any retained urine tends to be passed down to the fossa, so that an examination fifteen or twenty minutes after micturition will show whether the process has been successful, and any residue should be got rid of. If this is thoroughly carried out the intervals between micturition are at once lengthened. The rigour of treatment may be relaxed after a time, but vigilance is always necessary.

The theory of inspissation has not been verified, but the success of the treatment is a practical fact.—I am, etc.,

April 5th.

OCTOGENARIAN M.D.

SALVARSAN AND THE WASSERMANN TEST.

SIR,—In the issue of the JOURNAL dated March 19th, 1921, is published a paper on the treatment of syphilis by salvarsan. In that paper it is laid down that (1) salvarsan exercises a direct lethal action on the *Spirochaeta pallida*; and that (2) the Wassermann test indicates the presence of living spirochaetes.

Are we to conclude that this teaching is now accepted generally by the profession, and, if so, is it then the duty of those who undertake the treatment of syphilis to persevere with salvarsan until the reaction is negative, and is one to look upon all who exhibit a positive Wassermann reaction as requiring salvarsan treatment?

On the same morning lately I saw two patients. One was a woman with untreated syphilis of five years' standing and undoubtedly ill. Her reaction was negative, but became positive after a dose of salvarsan. The other was a man of 65, who admitted to gonorrhoea forty years ago but was positive he never had syphilis. Being a seafaring man he was naturally expert in the diagnosis of syphilis, and I believed his statement. He had none of the stigmata of congenital syphilis, and no signs of parasyphilis. His reaction was strongly positive. The tests were carried out by Professor Beattie of Liverpool—a sufficient guarantee of their accuracy.

Such experiences are not uncommon in venereal work, but they do not seem capable of explanation by the generally held views.

Is it not possible that salvarsan, instead of directly killing the spirochaetes, stimulates the body to do so by affecting its particular mechanism of defence against syphilis, and that it is the activity or lack of activity of this mechanism of defence which is demonstrated by the Wassermann reaction?

In the *Medical Century* (1914) is reported an experiment conducted by a Dr. Mellon of America, who administered to healthy students large quantities of a drug known as *Baptisia tinctoria*, causing the production in their blood of an agglutinin which would agglutinate typhoid bacilli, and proving thereby that a drug could be as successful an antigen as the disease toxin, and could influence the serum reaction in the same way as the disease.

In the light of this view the phenomenon of a positive reaction after a provocative dose of salvarsan is explained by the stimulation and resuscitation of a temporarily overwhelmed resistance. Looked at from the more generally accepted point of view it is difficult to explain, as, if salvarsan kills spirochaetes and the positive Wassermann is a proof of living spirochaetes, the chances of a negative reaction after the provocative dose ought to be greater than before it was given.

If salvarsan does act by stimulating the body's mechanism of defence against syphilis, may it not overstimulate it, paralyse it, destroy it? The negative Wassermann reaction, after a course of treatment, may mean a paralysed defence, with its increased liability to reinfection, relapse, or an earlier advent of the parasyphilides.

If this is so, then damage is being done every day with conscientious thoroughness.—I am, etc.,

Liverpool, April 5th.

F. B. JULIAN, M.D.

GLANDULAR FEVER.

SIR,—During the eleven years that I was school medical inspector to the West Riding County Council I had the opportunity of seeing a very large number of children suffering from the condition which Drs. Letheby Tidy and Morley call glandular fever. The symptoms were always the same—slight malaise and pyrexia, and com-

plaint of sore throat and difficulty of swallowing out of all proportion to the very slight objective changes that were observed in the fauces. The characteristic symptom, however, was the enormous enlargement of the sub-mucillary and peritonsillar lymphatic glands. This enlargement started on the second day of the disease, and continued to increase for about a fortnight, then remained stationary for some weeks and very gradually subsided. In many cases the condition of the glands suggested that they were going on to abscess formation or had become tuberculous, but I can say definitely that in no case did either abscess or tubercle develop.

The disease was met with always in epidemic form. I was able to fix the incubation period at three days. The epidemics were usually somewhat extensive, in many cases involving 25 to 40 per cent of the children attending the same school. The last epidemic that I remember was at Adel School, near Leeds, in, I think, 1917. Epidemics of this disease were extremely frequent on the South Yorkshire coalfield, and in the neighbourhood of Leeds. The public invariably called the condition mumps. I have never seen the disease outside the West Riding of Yorkshire.

My attention was first called to the condition from noting how very frequently epidemics of mumps were recorded in the schools in the West Riding. During some years I kept a record of the cases I had seen. They numbered several hundreds, but I regret that at the present moment I cannot put my hand upon my records.—I am, etc.,

DUNSTAN BEWFR.,
Medical Officer of Health

Swindon, April 9th.

SCURVY IN A BREAST-FED INFANT.

SIR,—In the review of Professor A. F. Hess's *Scurvy Past and Present* (BRITISH MEDICAL JOURNAL, January 15th, p. 85) he is said to make a statement to the effect that "infants brought up on natural milk do not contract scurvy." Some four or five years ago a strong, stout, healthy country woman whom I had confined, brought her child, only a few months old, to me, very bad indeed with scurvy. After examining the child I said, "If you lived in London, I would say your child had scurvy," and added that I had not seen a case for over fifteen years. Luckily I finally decided that it was scurvy in spite of the fact that the child was purely breast-fed, and I ordered orange juice, etc. On questioning the mother I found that she had been practically living on pickles, vinegar, and bread. The child was purely breast-fed, and on altering the mother's diet, etc., the child rapidly recovered.—I am, etc.,

A. NORRIS WILKINSON,
M.R.C.S., L.R.C.P.

Inglewood, Vic. Australia.
1 February 1920.

MEDICAL REGISTRATION.

SIR,—In view of recent legislation and protective regulations, I am directed to remind you that a medical practitioner, no matter what qualifications he may possess, is not "legally qualified" or "duly qualified" unless he is registered; and that the *Medical Register* is alone evidence upon this point "until the contrary is made to appear." There is no other book of reference which takes its place.

I am always pleased to answer inquiries by telephone (Langham 2500), or, better still, by letter, and to give all the information I possess in regard to practitioners. For those who specially require them, lists are prepared each month giving the names of all those registered during the month, and also of those who have died or whose names have been removed from the *Register* for any other reason.—I am, etc.,

NORMAN C. KING,
Registrar.

General Medical Council,
44, Haliam Street London, W.1.
April 7th.

THE Government of Panama have assigned ten million dollars for the erection of an institute for tropical diseases in memory of the late Surgeon General Gorgas.

THE second congress for Italian sanitary industries will be held at Palma in June, a little more than a year after the first congress, which was held at Milan. There will be an exhibition of medicinal plants and pharmaceutical apparatus and accessories.

Obituary.

PETER THOMAS DUNCAN, M.D.,

Consulting Physician, Croydon General Hospital.

WE regret to report the death, which occurred with tragic suddenness on Wednesday, April 6th, of Dr. Peter Thomas Duncan, of Croydon, in his 73rd year. He was acknowledged in the town as *facile princeps* in diagnostic skill. When in doubt or difficulty his aid was frequently sought by his brethren, and readily given to the last, for he died in harness, as he wished. His early life was a constant struggle against difficulty, but his indomitable pertinacity overcame all, and his career was distinguished. He received his medical education at University College Hospital, and in 1874 graduated M.B. with honours and B.S. with gold medal in surgery in the University of London. He took the M.D. in 1876, when he qualified for the gold medal. He held the office, then called physician's assistant, now known as house-physician, and was a fellow of University College.

He settled in Croydon and became physician to the Croydon General Hospital. From 1885 to 1893 Duncan was secretary of the East Surrey District of the British Medical Association, and in 1897 was president of the South Eastern branch.

The tributes we are able to publish from Sir Rickman Godlee and from Sir James Purves Stewart will explain Dr. Duncan's qualities as a practitioner of medicine. He was also remarkable for his sound judgement and wise forethought in business affairs. He was from an early date head of a large partnership in Croydon, and in recent years had organized it thoroughly on the team system. The aim he had was to ensure continuity of treatment to the patient, an opportunity to each partner to follow his particular bent in practice, while ensuring to all greater stability and security. Dr. Duncan leaves, a widow, a son, and three daughters, who with a large circle of patients and friends, mourn his loss. He was a cousin of the late Dr. Matthews Duncan, and a brother of the late Dr. William Duncan, gynaecologist to the Middlesex Hospital.

SIR RICKMAN GODLEE, Bt., who was a fellow student, writes: My feeling on hearing of Peter Duncan's death was that another familiar friend had gone; yet we had seldom met in past years, and probably should not have met again, for I, like so many others, had deserted my post, while he remained at his to the end. The real familiar days were long ago at University College in the seventies. There I remember him as a merry, hard-working student, who took many honours, held a resident appointment, was hail fellow well met with every one, and was liked and respected by us all. Then came the striving and penurious days of junior staff appointments, when I heard almost with jealousy of Duncan doing a large practice, but did not see much of him till I was old enough to be called into consultation. After that came many pleasant meetings scattered over many years. I looked forward to his genial welcome and his breezy manner and the pleasant chat over former days. But chiefly I was struck by his skilful and careful methods of diagnosis, his medical instinct, and his wisdom. He was one of those general practitioners from whom consultants, if they are wise, can learn much. There is no other way of picking up a very essential part of their knowledge, and few were so well able as he, though quite unconsciously, to impart it. And he was the leader and inspirer of a very vigorous band of colleagues; it is no small thing to be not merely one but the acknowledged head of such a distinguished body of men.

SIR JAMES PURVES STEWART writes: The news of Dr. Peter Duncan's death will be heard with sorrow by a wide circle of professional colleagues and friends. Starting his professional life with academic distinctions of the highest order, Dr. Duncan, in the course of a long and honourable career, accumulated a wide and deep knowledge of his profession and a shrewd judgement of men and affairs. Throughout a busy life his knowledge and experience were always freely at the disposal of his colleagues, many of whom, in moments of difficulty, turned to him for counsel and support, which were always freely forthcoming. A man of singular modesty and charm, his code of honour was a lofty one, and he was incapable of an ungenerous

thought or action. His friends, colleagues and patients, not only in Croydon but throughout the country, will condole with his widow and bright young family in their irreparable loss. He leaves behind him the memory of an upright man, a loyal friend, and an able physician—a heritage even more to be desired than the eminent position to which he deservedly attained.

J. HOPKINS WALTERS, M.R.C.S.,

Consulting Surgeon, Royal Berkshire Hospital, Reading.

With the death of Dr. James Hopkins Walters of Reading, at the age of 76, there passed away a notable character. Dr. Walters, who was a student at Guy's Hospital, took the diploma of M.R.C.S. in 1865, and he practised during his earlier days at Faringdon, Berks. In 1878 he moved to Reading, where he soon became one of the leading practitioners in the town, a position which he held until his retirement in 1913. He was on the active surgical staff of the Royal Berkshire Hospital from 1879 to 1904, and was then appointed consulting surgeon. He was president of the Reading Pathological Society for two years.

In his younger days Dr. Walters was a keen sportsman and an excellent shot; he also took a great interest in the Volunteers, in which for many years he was a surgeon-captain. In local politics he was a force with which to reckon, and he sat for a considerable period on the Reading Town Council. Always a fighter he had no hesitation in calling a spade a spade, and he stated his views, often original and always distinguished for sound common sense, in vigorous and picturesque language. He was a versatile writer, both in the medical press and in the lay journals. Although of the older school of medical men he was always receptive of new ideas. Even after relinquishing active practice in Reading he made a voyage half way round the world as a ship's surgeon. On the outbreak of war he volunteered for various posts which the authorities, on account of his age, were unable to grant him, and eventually he acted as medical officer to the regiment quartered in the town and to two V.A.D. hospitals.

On the eve of his death he had seemed in better health than usual, and had indeed played a game of billiards with keen interest at his club. Death occurred on March 4th suddenly in his sleep, as he had always desired—he was ever impatient of illness in himself.

JOHN WILLIAM FRY, M.R.C.S., L.S.A.,

Maidstone.

MAIDSTONE has recently lost the doyen of the local profession in the person of Mr. John William Fry, who died shortly after entering upon his 90th year.

Born at Greenwich in 1832, he was educated privately, and was in 1849 apprenticed to his uncle, Frederick Fry, F.R.C.S., surgeon to the West Kent Hospital, Maidstone, a gentleman of irascible temperament, who in the High Street once horsewhipped a fellow practitioner, and on another occasion hurled a row of filled medicine bottles at his unfortunate nephew's head. Harsh as were the conditions, Mr. Fry gained valuable experience, including that of cholera, an epidemic breaking out amongst immigrant hop-pickers at East Farleigh, attended with great mortality, the victims being buried in a common grave.

Leaving Maidstone, Mr. Fry entered at King's College Hospital, where he studied under Partridge and Ferguson. In 1855 he obtained the diploma of M.R.C.S. Eng., and became ship's surgeon to Messrs. Green and Co., sailing first to Australia and next to India in the Nile troopship, which reached Madras Roads a month after the outbreak of the Indian Mutiny, the troops being landed at once and rushed up to the relief of Lucknow. Returning to London Mr. Fry took the L.S.A. in 1859 and entered into general practice at Thaxted, Essex, where he again encountered a cholera epidemic at Great Sampford, taking up his residence in the stricken village and receiving the thanks of the Privy Council for his devoted services. In 1868 he moved to Wateringbury, Kent, where he practised for twenty-nine years, retiring to Maidstone in 1897, but again putting on harness to assist his fellow-townsmen in the typhoid epidemic which visited the town in 1898.

From his long connexion with Maidstone Mr. Fry was well known and much respected, and although he reached an advanced age, his interests remained many and his faculties unimpaired. He was an old member of the British Medical Association, and the oldest member of the Kent Medical Benevolent Society at the time of his death. He leaves three sons (all in the medical profession) and one daughter.

DR. CHARLES ALBERT HINGSTON of Plymouth died on April 5th, aged 78. He was educated at St. Bartholomew's Hospital and the University of Edinburgh, and graduated M.B. Lond. in 1864 and M.D. and B.Sc. in 1865. He took great interest in the Young Men's Christian Association, and was the moving spirit of the Western Counties division of that organization, to whose funds he generously contributed. For twenty-five years he was a director of the Devon and Cornwall Banking Company, now amalgamated with Lloyd's Bank. He was consulting physician to the Devon and Cornwall Ear and Throat Hospital and to the Plymouth Public Dispensary. Besides building a convalescent home, he established a deaf and dumb institute, and defrayed the cost of erecting a crypt at St. Augustine's Church. He was a member of the Plymouth Division of the British Medical Association.

THE sudden death of Dr. WM. MOIR of Darwen is recorded. He graduated M.B., C.M. Aberd. in 1892, and M.D. in 1897, took the D.P.H. Camb. in 1903, the B.Sc. (Public Health) Victoria University in 1908, and became barrister-at-law, Gray's Inn, in 1913. Before going to Darwen to succeed the late Dr. Armitage in practice he was medical superintendent of the Dunston Lodge Asylum, Gateshead-on-Tyne. He was one of the regional medical officers of the Ministry of Health under the National Health Insurance Acts for the North-Eastern Division of England. He was an ex-president of the Blackburn Division of the British Medical Association, and a member of the Society of Medical Officers of Health. He is survived by his widow and two children.

The Services.

R.A.M.C. AUXILIARY FUNDS.

THE annual meeting of the subscribers to the Auxiliary Royal Army Medical Corps Funds will be held at 11, Chandos Street, W.1, on Friday, April 29th, at 4 p.m.

HONOURS.

FOREIGN DECORATIONS.

THE President of the French Republic has conferred the Cross of Chevalier of the Legion of Honour upon the following in recognition of their services to the French sick and wounded at Hôpital Bénévole, No. 115 bis, at Villeneuve-sur-Lot during the late war: Dr. W. R. Dakin, Dr. F. M. Graham and Dr. A. Kirkpatrick Henry.

DEATHS IN THE SERVICES.

SURGEON-COLONEL CHURCH CUMBERLAND ROSS, Bengal Medical Service (retired), died April 11th, aged 78. He was born on December 1st, 1843, at Kilkenny, he was educated in Dublin, taking the L.R.C.S.I. in 1864, and the L.K.Q.C.P. in 1865. He entered the I.M.S. as assistant surgeon on October 1st, 1865, became full colonel on January 1st, 1894, and retired on October 1st, 1897. Most of his service was spent in civil employ in the Punjab, where he was for many years civil surgeon of the important stations of Delhi and Rawal Pindi in succession. On reaching the administrative grade, he filled the post of inspector-general of civil hospitals in the Central Provinces for a year, and afterwards the same post in Bengal. His son, Staff Surgeon G. C. C. Ross, R.N., lost his life early in the war in H.M.S. Hawke torpedoed in the North Sea on October 15th, 1914.

Brigade-Surgeon John Trchane May Symons, R.A.M.C. (retired), died at Cheltenham on March 11th, aged 87. He was born at Tintagel, Cornwall, on September 1st, 1833, took the L.F.P.S.G., the L.S.A. and the M.D. of Gießen University in 1855, and entered the army as assistant surgeon on December 8th, 1857, more than sixty years ago. In the regimental days he served in the Royal Artillery. He attained the rank of brigade-surgeon in 1883, and retired on September 1st, 1883.

Colonel C. H. Melville, C.M.G., A.M.S. (ret.), will give a lecture on "Some Lessons of the War," at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1, on Wednesday, April 27th, at 5.30 p.m. The chair will be taken by the Earl of Plymouth.

Medical News.

THE Royal Institute of Public Health will hold a series of conferences in London at the end of the first week in June. On Thursday, June 2nd, there will be discussions in the morning on municipal hygiene and its suggested connexion with the administration of the Poor Law and the future of voluntary hospitals, and in the afternoon on the housing problem. On Friday morning there will be a discussion on the prevention of ill health in industry, and in the afternoon on venereal diseases and the additional measures necessary for their prevention; on Saturday morning the discussion will be on the present machinery for dealing with tuberculosis. Further particulars can be obtained from the honorary secretaries, 37, Russell Square, London, W.C.1.

SIR LEONARD ROGERS has been appointed extra physician for clinical research and lecturer, and Lieut.-Colonel W. Clemesha lecturer on hygiene of the tropics, at the Hospital for Tropical Diseases and the London School of Tropical Medicine.

A THREE MONTHS' course of lectures and demonstrations in hospital administration for the diploma in public health is being given at the Western Hospital, Seagrave Road, Fulham, by Dr. R. M. Bruce, medical superintendent, on Tuesdays and Fridays, at 5 p.m. Applications should be made to the Clerk to the Metropolitan Asylums Board, Embankment, E.C.4, giving full name and address.

ON the recommendation of the Minister of Health, the King has been pleased to appoint Miss Ruth Darwin to be a Commissioner (unpaid) of the Board of Control.

THE inaugural meeting of the Institute of Physics will take place on Wednesday, April 27th, at 6 p.m., in the hall of the Institution of Civil Engineers, Great George Street, Westminster. Sir Richard Glazebrook, K.C.B., President, will preside, and Sir J. J. Thomson, O.M., will deliver an address. Mr. A. J. Balfour is expected to be present and extend a welcome to the institute. Non members of the institute or of the societies associated with it may obtain tickets of admission on application to the Secretary, 10, Essex Street, Strand, W.C.2.

A COURSE of ten lectures on ante-natal and post natal child physiology will be given by Dr. W. M. Feldman, in the physiological theatre of the London Hospital Medical College, on Mondays, at 5 p.m., beginning on April 25th, and Dr. Millars Culpin will deliver a course of fourteen lectures on psychoneuroses in the clinical theatre of the hospital on Tuesdays and Fridays, at 5.15 p.m., commencing on May 3rd. Further particulars can be obtained on application to the dean of the college.

A POST GRADUATE course of lectures and demonstrations will begin at the National Hospital for the Paralyzed and Epileptic, Queen Square, on May 2nd, and will be continued on each Monday, Tuesday, Thursday, and Friday till June 24th. Mr. Leslie Paton will give a series of six lectures and demonstrations in neurological ophthalmia, beginning on May 11th, and Dr. Greenfield a course in pathology if sufficient entries are received. Mr. Armour and Mr. Sargent will operate on Tuesday and Friday mornings, or at such other times as may be announced. The fee for the post-graduate course is seven guineas; for the course in ophthalmology, if taken with it, two guineas, and for the course in pathology three guineas. The Fellowship of Medicine's ticket will not admit to these courses.

THE Leicester Medical Society has arranged a course of post graduate lectures to be given at the Royal Infirmary, Leicester, at 4.45, on Wednesdays, from April 20th to May 18th. Dr. Arthur Hunt will lecture on gastric and intestinal diseases on April 18th and May 4th. Dr. G. F. Still on urinary disorders in childhood and on dietetic causes of disease in infancy and childhood on May 11th and 18th, and Mr. R. C. Elmslie on manipulative surgery on April 27th.

AT a meeting of the Executive Council of the Federation of Medical and Allied Societies on April 5th it was announced that its incorporation had been satisfactorily completed. Sir Berkeley Moynihan, K.C.M.G., C.B., M.S., of Leeds, was elected president, and Sir Malcolm Morris, K.C.V.O., F.R.C.S.E., the Chairman of Council, was elected vice president. The Federation now has (1) a medical council, (2) a council of allied professions, and (3) a citizens council. Each society is to have a representative on the council appropriate to its professional interests. The British Association of Radiology and Physiotherapy was elected to membership.

DR. DAN MCKENZIE has been elected a Corresponding Fellow of the American Laryngological Association.

A MEETING of the Brompton Society will be held on Thursday, April 21st, at 8.15 p.m., in the Physics Lecture Theatre, University College, Gower Street, when a paper on a new form of stereo-scope will be read by Professor A. M. Tyndall and Mr. E. G. Hill, and descriptions and demonstrations will be given of new apparatus. A meeting of the Society is to be held at Manchester on May 6th, when Professor W. L. Bragg will read a paper and Professor A. V. Hill will demonstrate some physiological experiments.

DR. L. RIST has arranged a ten days' advanced course on tuberculosis in Paris for the latter part of May; the subjects to be treated will include artificial pneumothorax, experimental reinfection, the extent to which x-ray work has affected ideas regarding the pathology and diagnosis of lung tubercle, etc. One day will be spent at the hospital for surgical tuberculosis at Becq-sur-Mer, and a visit has been arranged to Bigny Sanatorium; visits will be paid also to the Rockefeller Dispensaries, Pasteur Institute, Larancé Hospital, and other institutions. Further particulars can be had from Dr. W. H. Dickinson, 91, New Bridge Street, Newcastle upon Tyne.

ACCORDING to a recent census, the total population of Russia has been reduced by about 10 per cent. The diminution amounts to 45 per cent. in Moscow and 71 per cent. in Petrograd, and is very pronounced in all the cities. In the country districts, on the other hand, it is very slight.

THE King's Fund Policy Committee has just issued an interim report, dated April 4th, 1921, on the policy to be recommended for the preservation of the voluntary system of hospital management and control. Copies of this interim report and of the thirteen resolutions passed by the President and General Council on January 26th last may be obtained from King Edward's Hospital Fund for London, 7, Walbrook, E.C.4.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ACTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 422, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 422, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London, telephone 2530, Gerrard.
2. ASSISTANT SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2530, Gerrard.
3. MEDICAL SECRETARY, *Medicera*, Westrand, London; telephone, 2530, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams, *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"W. A. R." who is treating a woman of 55 suffering from severe rheumatoid arthritis of one knee, believes that if the joint could be fixed she could get about without pain. Would fixation in plaster, he asks, be of any use in producing ankylosis, or is excision of the joint ever justifiable in such a case? No other joint is affected.

INCOME TAX.

"T. M. C." asks for further advice as to liability in respect of cash coming to his hands after he has sold his share in the practice. His previous answer was published on March 5th, 1921.

"We are clearly of opinion that he is not liable, and suggest that the inspector of taxes, whose letter he has forwarded, does not appreciate the point. Simply stated, this is that when "T. M. C." ceases to do professional work his income ceases also; what he receives is in respect of past earnings, and he has paid tax on those earnings. Of course, not specifically on those receipts, but on other receipts which

were taken as equivalent thereto. The revenue authorities refuse to assess a commencing practice—or incoming practitioner—on the basis of cash receipts, holding, reasonably enough, that in the early years these do not provide a sufficient index to the earnings of the practice. The obvious corollary to that proposition is that cash received when the earning has ceased represents the recovery of fees which have already paid tax.

"J. J. M." is an assistant medical officer at an asylum receiving a salary plus emoluments, "not negotiable for cash," valued at £120. He inquires whether he is liable to pay tax thereon.

* * No; the case is covered by a decision of the House of Lords in *Smith v. Tennant*.

LETTERS, NOTES, ETC.

DR. FREDERIC VICARS writes: Apropos of your interesting article on Alexis Soyer, the celebrated chef, the following note is worth recording: Though his wife was a person of violent temper and gave him many a *mauvais quart d'heure*, Soyer was devoted to her. On meeting a celebrated member of the Reform Club just after her death, the disconsolate Soyer asked him to suggest an epitaph for her tombstone. "Soyez tranquil," was the prompt reply.

MILK REGULATIONS.

REGULATIONS recently issued by the Food Controller and the Minister of Health continue in force the provisions which are already contained in the Orders of the Food Controller regarding the control of the quality of milk. Licences for the sale of Grade A and Grade A (Certified) milk will in future be issued by the Ministry of Health instead of by the Food Controller, and local authorities will be able to take steps to prevent milk being sold in any area under any of these designations, or "milk" which has been made up from dried milk or condensed milk, without such a licence. Similarly, no milk or cream to which any colouring matter or water has been added must be offered for sale. The licensing of wholesale dealers in milk and the registration of retail dealers will be continued for the present by the Board of Trade as the successor of the Food Controller.

EMETINE IN BILHARZIASIS.

"B. H." writes: Dr. Harkness, in the *BRITISH MEDICAL JOURNAL* of December 11th, 1920, page 890, writes on the superiority of sodium antimonium tartrate over emetine in the treatment of bilharziasis, mentioning that he was taking, or being given, emetine gr. 3, and that no improvement was noticed. The doses, however, advocated from Egypt have been gr. iij every third day or so, and the smallness of Dr. Harkness's dose will no doubt account for the apparent failure. In my own hands emetine doses of gr. iij every third day has given the best pleasing results; and usually only four have been required—anaemia, urine and general debility quickly clearing up. The immediate after-effects of such a large dose of emetine is sometimes a feeling of nausea and even vomiting, but usually no discomfort is felt in adults; a child of 10 years will easily stand gr. 2½. These remarks are not meant to advocate the use of emetine in place of antimony, which latter has proved its worth in bilharziasis. Certainly one great virtue in emetine is the simplicity of administration—intramuscular into the deltoid and lumbar region.

THE TREATMENT OF PNEUMONIA.

WE have received from Dr. R. W. Burkitt, F.R.C.S.I. (Nairobi), a communication in the course of which he says: For some years past I have treated acute pneumonic fever on the following general principles, and I have now successfully treated 250 cases in this way, chiefly Europeans, but including Asiatics and a few natives of Africa. I have not only never lost one who came under treatment early, but, provided I saw my patient within the first twenty-four hours of his fever, I have had no anxiety as to his recovery. I should not advise anyone to adopt the method of treatment unless he means to be thorough—half measures are of little value. Briefly, my principles of treatment are in this order: (1) The temperature is kept under 101°; (2) severe purgation is employed during the first twelve to twenty-four hours, afterwards a daily motion; (3) acidosis is avoided by giving potassium citrate; (4) enormous quantities of water are drunk; (5) absolutely no nourishment of any kind whatever is allowed until the fever is over, the tongue clean, and the patient hungry; (6) no stimulants of any kind are allowed. The keeping of the temperature under control, in this country where we have a big evaporation, is effected by the patient being at once put on a waterproof sheet, absolutely naked except his feet, the whole body being kept continuously wet and placed in a draught so as to get the maximum evaporation. The feet are kept warm with socks and a hot bottle; this makes the patient comparatively comfortable. Patients only complain of the treatment at first; in a few hours they get to see the value of it. There must be no half measures here—thoroughness always saves life. When the temperature is 100° the patient is allowed a sheet, as it tends to make him sleep, but if his temperature goes up much it is taken away. Sometimes with a sheet the temperature may run up 1° to 2°. When it goes below 100° he is allowed further clothing, but he is

treated according to the temperature at the time. As to purging, there must be degrees of severity according to the fullbloodedness of the patient and the amount of toxæmia present. In a fullblooded patient the beginning, I help the purging by at c the beginning, or so. This gives immediate relief to the right heart and to the whole system in a lessening of toxins. If done late bleeding does harm, the reason probably being that the antitoxins then made are bled out. In a case not seen until late on, heavily intoxicated and blue, I think the best thing is to purge severely, but not to bleed. I purge with calomel and Epsom salts for the first twelve to twenty-four hours only, and afterwards I secure a liquid motion daily with a light saline.

Acidosis is common in pneumonia, and, therefore, all my patients receive a teaspoonful of potassium citrate three times a day, although some require far more. It is impressed on every patient that his life depends on the amount of cold water he drinks; he is kept frequently urinating. I have found that the giving of any food during any fever (even a little diluted milk) is definitely prejudicial until the fever is finished, the tongue clean, and he is hungry. I have kept a fever patient as long as six weeks on pure water with none but the happiest results.

CLIMATE OF THE RIVIERA.

DR. JULIAN TAPLIN writes with reference to two topics touching the climate of the Riviera. He has been residing at Saint Raphael, on the main boulevard, and complains that, though it is the main route to the Eastern Riviera, the road is not kept cleansed and watered, so that there is a great deal of dust. The other point is that he desires to hear of some place within easy reach of the Riviera, which would be suitable for a case of chronic pulmonary tuberculosis during the summer.

THE RUPEE EXCHANGE.

"HAKIM" writes: The rupee, which was worth two shillings and elevenpence a year ago, is worth only one shilling and threepence to-day, and its value is falling steadily. No prospects of granting of exchange compensation are held out, and twenty rupees may soon be equivalent to one pound sterling. Passages to and from India are all quoted in sterling, and as the rupee falls in value so does the cost of passages in rupees rise. A second class return passage from India now costs just over two thousand rupees. It is possible for a bachelor to save enough from his salary to pay for his return passage, but it will use up all his savings. With the rupee at sixteen to the pound and likely to go to twenty, any man who contemplates matrimony must reconcile himself to perpetual exile.

AN ELECTRIC THERMOSTAT.

THE Wild-Barfield electric thermostat appears to be constructed on a new plan; a capsule filled with a volatile fluid is made, by its expansion, to switch off a part of the heating element as soon as the full temperature is reached. Afterwards the full current is switched on and off intermittently, so that a temperature is maintained steadily at the desired height. The device, which can be set for temperatures up to 400° F., is made by Automatic and Electric Furnaces, Ltd., 281, Gray's Inn Road, W.C.1.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 34, 35, 36, 37, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33.

THE appointment of certifying factory surgeon at Burton-upon-Trent (Stafford) is vacant.

"CAPT. R.A.M.C." has omitted to enclose his name and address.

REDUCTIONS of approximately 20 per cent. in the price of motor covers and of 15 per cent. in that of inner tubes are announced by the Stepney Company.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line...	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive poste restante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

453 Haemolytic Jaundice

LORENZINI (*Il Voigtman*, January 31st, 1920) published a case of this disease in a child aged 12, and took the opportunity of discussing the subject at some length. Historically little was written about it before 1900, when Minkowski described a case. There are two main groups—acquired secondary haemolytic jaundice and primary. The first group depends on infective agents (for example, pneumonia), parasites (malaria), poisons (chloroform), or physical causes—for example, cold. The second group includes the so called congenital haemolytic jaundice, which may be of two types (Minkowski, Chauffard or Hayem-Widal). The chief symptoms of primary haemolytic jaundice are: (1) Jaundice, but this is not as constant as was at one time believed. (2) The faeces are always well coloured and rich in bilin. (3) Acholuria is almost always present. (4) Splenomegaly rarely is absent. (5) Enlargement of the liver is usually present but slight. (6) Anaemia of haemolytic type is an important symptom; the leucocytic formula is usually normal; the granular blood cells derived from the bone medulla may be present, but are not of such diagnostic importance as was at first believed. The globular fragility under hypotonic salt solution is an important differential sign. Authorities are not agreed as to the etiology and pathogenesis, although the favourable results that have followed splenectomy seem to implicate that organ. Some relation probably exists between haemolytic jaundice, Hanot's cirrhosis, and Banti's disease, and the author discusses this rather fully. The differential diagnosis is chiefly concerned with chronic catarrhal jaundice, Hanot's cirrhosis, proxyermal haemoglobinuria, familial jaundice, and pernicious anaemia; and perhaps the most important differentiating sign that distinguishes haemolytic jaundice is the globular fragility in the presence of hypotonic salt solutions. The prognosis, as far as the primary congenital forms are concerned, is good. The only treatment that seems useful is splenectomy—for example, Calnet reported 47 cures in 54 operated upon.

454 Tincture and Infusion of Digitalis in Therapeutics

TINCTURE of digitalis was prepared by WEISS and HATCHER (*Journal Amer. Med. Assoc.*, February 19th, 1921), the marc of which was dried and used in the preparation of an infusion, this infusion of marc was tested on cats, and found to be inert, showing that all of the active water soluble principles of the leaf are extracted during the percolation for making the tincture. This method of testing the marc affords a delicate means of finding the degree to which the active water soluble principles are extracted during the percolation of the drug. There is no essential difference in the amounts of the saponin bodies present in the tincture and in the infusion prepared from equal weights of the leaf, and therapeutic doses of digitalis do not contain enough to induce any undesired effects. Infusions of digitalis were prepared in different ways. In each case the marc was washed and dried, after which it was used for the preparation of tincture, and this tincture was tested on cats in order to determine to what extent the active principles had been extracted during the preparation of the infusion. The official infusion does not represent the drug completely; hence the standardization of the leaf does not ensure uniformity in activity of the infusion. The variability of the infusion is at the expense of the more absorbable of the active principles. The infusion prepared according to the method described represents the activities of the leaf completely; hence it permits of uniformity when a standardized powder is used for making it. It may be used in place of the tincture in doses just ten times the volume of those of the latter, and it becomes a matter of indifference, so far as therapeutic effects are concerned, which is used. The authors have been unable to discover any experimental evidence to support the view, still held by many, that there is a necessary qualitative difference between the actions of the tincture and those of the infusion of digitalis, even when the latter is prepared properly. An infusion of digitalis prepared in the manner recommended, and kept in completely filled and hermetically sealed bottles for more than two years and five months, retained its activity unimpaired, as shown by the results of tests on cats and by the therapeutic effects on man.

455 Intestinal Tuberculosis and the Anaemia of Consumptives

His investigations in the tuberculosis wards of the Oesunds Hospital have led KRAH MOLLER (*Acta Medica Scandinavica*, January 14th, 1921) to correlate the anaemia of pulmonary tuberculosis with tuberculous disease of the small intestine. His first series of cases, establishing this correlation, were obtained from hospital records. His second series of cases were personally investigated, and his material was not "selected" in any other way than that he concentrated on cases likely to be soon available for post mortem examination. About 130 patients were examined, 49 of whom were also examined post mortem. Monthly examinations of the blood were undertaken with Antenneith Königberger's apparatus for determining the percentage of haemoglobin. As the author's table shows, the consumptives who suffered from tuberculosis of the small intestine were much more anaemic than those who escaped intestinal tuberculosis, or whose intestinal tuberculosis was confined to the large intestine. It was also noted that the higher the position of tuberculous ulceration in the small intestine the more severe was the anaemia. In the two worst cases of anaemia (30 per cent. and 16 per cent. haemoglobin) the jejunum was involved. The author suggests that the anaemia of intestinal tuberculosis is not due to haemorrhage from the bowel but to absorption of haemolytic toxins. This explanation would account for the fact that patients with tuberculosis of the large intestine are less anaemic than those with tuberculosis of the small intestine, because the former condition provokes diarrhoea which prevents the absorption of toxins. This diarrhoea also helps to conceal the anaemia by making the blood more concentrated.

456 The Relation of Lethargic Encephalitis to Influenza.

ALMASIO (*Il Policlinico*, 50, Prat., February 14th, 1921) states that there was an epidemic of 133 cases of lethargic encephalitis at Turin between December, 1919, and April, 1920, 4 occurred in the second half of December, 74 in January, 13 in February, and 17 in March, 48 died—a mortality of 34 per cent. The death rate was highest after 60 (6 deaths among 11 cases), fairly high from 20 to 30 (18 deaths among 47 cases) and from 30 to 40 (7 deaths among 31 cases), and lower from 10 to 20 (4 deaths among 19 cases). The mortality in children under 10 was fairly high (3 deaths among 9 cases). The lowest mortality was from 50 to 60 (1 death among 6 cases). The two sexes were almost equally affected, 74 of the cases being in males and 64 in females, 72 had not had influenza in 1918, and only 12 had been attacked then. In 38 the disease started suddenly, and in 14 the symptoms of encephalitis appeared as a complication or sequel of influenza. All social classes were affected. No example of contagion was observed. The influenza epidemic of 1920 in Turin closely corresponded with the epidemic of lethargic encephalitis. It gradually increased in intensity from the beginning of January till the 29th, progressively diminished in February, and completely ceased at the end of March. In both influenza and lethargic encephalitis the majority of cases occurred in persons between 20 and 30 years of age. The curves of the two diseases, however, differed as regards the number of those affected in early life. Whereas in encephalitis there were very few patients between the first and fifth years of life, in influenza there were many cases at this age.

457 Congenital Syphilis in the Second Generation

SIDLER HUEGENY (*Schweiz. med. Woch.*, January 20th, 1921) throws light on the fate of syphilis in the second generation by a study of the progeny of the subjects of congenital syphilis. He found that of 250 such persons, 50 had married. Of these marriages 14 were sterile, and the remaining 36 marriages were followed by the birth of only 65 children. As an earlier investigation by the author showed, 48.7 per cent. of the subjects of congenital syphilis die in childhood, and those who survive childhood often succumb later to their syphilis, to rickets, or to tuberculosis, to which they are markedly predisposed. But though the subjects of congenital syphilis seldom marry, and if they do so, seldom breed many children, neither these children nor the persons whom the subjects of congenital syphilis marry develop syphilis itself. In spite of careful clinical, radiological, and serological examinations of all but 5 of

the 65 children born to the subjects of congenital syphilis, the author could find syphilis in one case only. Even this case he is doubtful about. Wassermann examinations of 12 women who had married the subjects of congenital syphilis proved negative in every case. Yet, if transmission of the disease were feasible under these conditions, its existence in the wife ought to be demonstrable by Wassermann's test. The author is accordingly very dubious as to the possibility of congenital syphilis being transmitted from husband to wife, or from parent to child. He ends his paper, however, with the advice that, when a woman suffers from congenital syphilis, her blood should be tested before marriage, and if Wassermann's reaction proves positive she should undergo a thorough combined course of specific treatment. Even if this does not convert a positive to a negative Wassermann reaction—and the chances of this conversion are small—it is yet probable that this treatment would have a beneficial effect.

458. Vaccination in Country Districts.

GIOSEFFI (*Il Policlinico*, Sez. Prat., January 10th, 1921) states that the year 1919 was bound to produce an outbreak of small-pox owing to the return of prisoners of war from enemy centres infected with the disease. In the towns where prompt precautionary measures, such as isolation, disinfection, and vaccination on a large scale had been carried out, the population was mostly refractory to small-pox, especially as it was the practice to vaccinate the children during the school period and adults on admission to public appointments, and in seacoast towns before embarkation. Country districts, on the other hand, were not so protected, owing to the tendency of the ignorant country folk to escape vaccination as far as possible. Gioseffi suggests that presentation of a certificate of revaccination should be made compulsory before marriage and admission to religious services, and that general vaccination or revaccination should be carried out every spring.

459. Herpes of the Anal Region with Meningeal Symptoms.

RÉNON and BLAMOUTIER (*Soc. Méd. des Hôpitaux*, February 3rd, 1921) report the case of a woman, aged 35, who was admitted into hospital on October 5th with a history of four days' intense and increasing headache, photophobia, stiff neck, typical Kernig sign, and vomiting. Lumbar puncture showed raised tension, nothing abnormal cytologically. Next day the meningeal symptoms were much better, but around the margin of the anus there was a definite eruption of herpes. A second lumbar puncture showed normal fluid tension, a few lymphocytes, and some staphylococci. In the herpetic area there was absolute anaesthesia. The patient left the hospital convalescent on October 26th. When seen again, in January, she complained of headache, especially after fatigue—a lumbar puncture gave a fluid nearly normal.

460. Pulmonary Influenza in Children.

BOSSERT and LEICHTENTRITT (*Deut. med. Woch.*, February 10th, 1921) are convinced that, since the recent epidemics of influenza, many cases of chronic pulmonary disease in children can be traced to infection with Pfeiffer's bacillus. They describe four different types of influenzal disease of the lungs. The first is characterized by a fairly chronic course, but complete recovery follows after a period of weeks or months, during which there seems to be little or no change in the physical signs. In the second type the disease runs a more intermittent course, and the physical signs do not persist with the same severity throughout the child's illness. In the third type there is no change in the physical signs over a period of years, and in the fourth type the disease terminates fatally with bronchopneumonia. The authors give details of several illustrative cases, and stress the points of significance in the differential diagnosis of influenza and tuberculosis. In young children a negative von Pirquet reaction is instructive; the presence of Pfeiffer's bacillus in, and the absence of the tubercle bacillus from, the sputum are also indicative of influenza. A sign which the authors found to be common in these cases of chronic influenzal bronchiectasis was a machine-gun-like rale heard behind the lower lobes. In one of the cases described the adventitious pulmonary sounds cleared up under treatment with potassium iodide. The authors conclude that post-influenzal bronchiectasis and other chronic pulmonary changes are remarkably common as a sequel to influenza in childhood, and they insist on the importance of sifting out such cases from those which are due to the tubercle bacillus, for the exclusion of pulmonary tuberculosis saves the patient from the stigma and costly treatment entailed by this diagnosis.

SURGERY.

461.

Lumbar Anaesthesia.

RICHTER (*Hygiea*, February 28th, 1921) has investigated the results obtained by lumbar anaesthesia in the 601 cases in which this form of anaesthesia was adopted at his hospital since 1905. He found that the anaesthesia was complete in all but 5.8 per cent. of the total; the failures to induce complete anaesthesia referred almost exclusively to operations on the upper segments of the abdomen, while it was almost invariably complete in amputations below the hip. He did not attempt operations on the upper half of the body under lumbar anaesthesia, and he agrees with those authors who set the umbilicus as the level above which operations should not be performed under lumbar anaesthesia. He never experienced any fatality or serious accident, such as cessation of pulse or respiration, permanent paralysis, trophic disturbance or the like, as a sequel to lumbar anaesthesia. He associates this immunity to alarming complications with his careful selection of cases and his avoidance of Trendelenburg's position, in which patients are placed by most surgeons directly after the injection. The author keeps his patients horizontal, with the head propped up with a couple of pillows. Reviewing the experiences of thirty-four writers whose 26,446 cases of lumbar anaesthesia between 1917 and 1920 included twelve deaths (0.045 per cent. mortality), the author points out that practically all these deaths could be traced to the serious condition of the patient before the lumbar injection. Though the author finds lumbar anaesthesia both safe and comparatively effective, he tempers his advocacy of this method with the admission that recent advances in the technique of local anaesthesia have done much to displace lumbar anaesthesia. This has, however, its sphere of usefulness when, after an accident, for example, the surgeon cannot wait the fifteen to twenty minutes required for certain forms of local anaesthesia, or when the patient is disqualified by senile gangrene or other causes for general anaesthesia.

462. Tuberculosis of the Male Genital Tract.

BARNEY (*Amer. Journ. Surg.*, December, 1920) discusses the treatment of tuberculosis of the genital tract in the male. He believes that the epididymis is the primary focus, but that this is itself always secondary to a focus elsewhere in the body—most often in the lungs or hilus glands. He believes equally that tuberculosis of the prostate and seminal vesicles is almost invariably secondary to that of the epididymis. Primary tuberculosis of the prostate does exist, but it is extremely rare, and very few genuine cases have been recorded in the literature. Such a case has never been met with by Barney and his colleagues at the Massachusetts General Hospital. They have found that prostatic tubercle tends to spontaneous cure after epididymectomy, and do not think that radical operations on the prostate and vesicles are justifiable or necessary. The diagnosis of tuberculosis of the epididymis is often difficult; a gonococcal prostatitis may obscure the true nature of the disease in the epididymis. Barney believes that an exploration under novocain should be advised in doubtful cases. He describes two cases to emphasize the importance of this. In both, after much loss of time and palliation, orchidectomy was performed, and the enlargement proved to be a sarcoma springing from the testicle. The author holds that epididymo-vasectomy is the operation of choice, performed preferably under novocain. He has lost cases after operation from miliary tuberculosis, and believes the inhalation anaesthesia (ether) to have been largely responsible for this. Orchidectomy is rarely necessary; even if the testis is affected the diseased portion can be successfully removed in many cases. The second epididymis is involved in at least half the cases, and will need removal. The prostate and seminal vesicles, although early invaded, do not require direct operative measures, and will heal after the epididymal foci have been excised.

463. End-results of Operation for Varicocele.

DURING the period immediately preceding and after the entrance of the United States into the war, and while recruiting was in active progress, a large number of operations for varicocele were performed on young men in order to permit their entrance into the army or navy. As a result of one of these operations, in which the ligation of the veins was followed by the development of a hydrocele, a suit for alleged malpraxis was brought. DOUGLAS (*Journ. Amer. Med. Assoc.*, March 12th, 1921), after a study of the end-results of 303 operations for

varicocele at St. Luke's Hospital, New York, reached the following conclusions: The operative treatment of varicocele is often followed by hydrocele. Of a total of 303 operations, 76 patients were examined, 30 of whom, or 39 per cent., had a hydrocele; 40 reported by letter or telephone, and of these 7, or 17 per cent., stated that hydrocele had developed. Of the total of 106 patients examined or reporting by letter, 37, or 35 per cent., had hydrocele; 4, or about 4 per cent., had atrophy of the testicle, and there were two recurrences of the varicocele. He considered that the operation should not be performed except in those cases of very large varicocele giving marked symptoms in a non-neurasthenic patient—certainly not in the type of cases previously referred by the various medical examining boards for admission to the army or navy. If the operation is undertaken, the frequency of hydrocele as a complication should be explained to the patient as a protection to the operating surgeon. In the performance of the operation every care should be taken to avoid trauma to the veins of the cord and to prevent haematoma or the slightest infection, thus limiting thrombosis and also avoiding the ligation of the spermatic artery as well as the artery of the vas.

462. Acute Infections of the Pancreas

SWEET (*Poston Med. and Surg. Journ.*, February 10th, 1921) discusses the surgical treatment of pancreatic infections. The symptoms of acute pancreatitis are those of upper abdominal peritonitis, and they so closely simulate those of perforation of the gall bladder, duodenum, stomach, and acute cholecystitis, that it is impossible to be certain prior to operation. The patient's extremely ill appearance and grave condition are notable, but the only sure sign is the finding of fat necrosis or free blood stained fluid, with palpable disease of the gland at operation. Success depends upon early and prompt operation and the provision of ample drainage. The coincident gall bladder disease must be dealt with at the same time. Post-operative history is more or less stormy from attacks of epigastric pain and vomiting, and the worst cases slough out part of the gland, the functional margin of safety of which is estimated at two thirds of the gland substance. Notes of six cases with one death are given, pointing to the fact that, if diagnosed and operated upon early, acute pancreatitis is not so hopeless a condition as it has been hitherto considered.

465 Injections of Milk in Gonorrhoeal Conjunctivitis.

LINDBLAD (*Hygica*, January 30th, 1921) states that for the past year and nine months every case of gonorrhoea of the eyes at the Sabbatsberg Hospital has been treated with intraglandular injections of boiled cow's milk in addition to the customary local treatment. To ascertain the value of this milk therapy, the merits of which have been loudly proclaimed, the author has compared the results of the milk with the milk regime. In the first category the patients received only local treatment. Of 13 adults in this category, 5 responded well, 5 badly, and 3 were hopeless at the beginning of treatment. In the second category the results were good in 1, fairly good in 2, and very bad in 1 case. The patients treated without milk became gonococcus negative after an average of twenty-two days, and the milk treated after ten days. Turning from adults to children, the author found that without milk treatment they lost their gonococci after seven to eight days, the milk treated after ten days. The author concludes that, though this milk treatment may be beneficial in some cases, it does not deserve the reputation it enjoys in certain quarters.

466 Carcinoma of the Tongue.

PETERS (*Deut. Zeit. f. Chir.*, June, 1920) analyses the statistics of 48 cases of carcinoma of the tongue in Garré's clinic. Only 5 were admittedly heavy smokers and only 5 gave a history of syphilis. The characteristic of tongue carcinoma is its insidious, unnoted onset and the short span on life of the sufferers. Secondary gland involvement occurs early and is of vital importance, as it progresses rapidly and may render operation difficult or impossible. Interference with the free movement of the tongue was a common sign. Results of operation were disappointing, not more than 6 cases being free from recurrence for over two years (15 per cent.). However, removal of the primary growth, even when lasting cure is not attained, lengthens the prospect of life by a few months. Propaganda is still urgently needed amongst practitioners to urge them to send cases of tongue neoplasia for expert examination. Even if the patient is admittedly syphilitic, his ulcer may very well be carcinomatous.

OBSTETRICS AND GYNAECOLOGY.

467. Treatment of Febrile Cases of Abortion

PRIZINGA (*Zentralbl. f. Gynäkol.*, March 19th, 1921) makes yet another contribution to the active discussion which has taken place in Germany during the past ten years with regard to the comparative value, in cases of abortion and parturition which are followed by pyrexia, of (1) conservative or expectant treatment and (2) operative treatment (by emmeting). His verdict, based on an analysis of 436 cases of septic abortion, is given very definitely on the side of the rapidly increasing minority who advocate conservative or expectant treatment. Of these cases 145 received "active" treatment—that is, emmeting performed during the febrile stage. 185 had "expectant" treatment—that is, the emmeting was deferred to the second, third, or fourth day after the temperature had fallen to normal; the remaining 105 were given "conservative" treatment, consisting in rest and general medical attention, without recourse to operation. Prizinga again subdivides his cases according as the temperature at the time of admission to hospital was below or exceeded 100.4°, he proceeds to detail the differences shown by the different groups with regard to the duration of the pyrexia, the persistence of the bleeding, the time required for cure, the number and character of the complications, and the mortality. In the cases treated "actively" the average time elapsing between admission and the disappearance of fever was 5.8 days (admission temperature having been less than 100.4°) or 6.9 days (the temperature having been greater than 100.4°). For cases treated "expectantly" the corresponding figures were 2.0 days and 3.1 days; for the "conservatively" and "expectantly" treated groups together, 3.9 days and 6.9 days. The average duration of the bleeding was 3.6 days and 4.3 days respectively in cases treated actively and expectantly—a slight advantage for active therapy which is more than counterbalanced by its drawbacks in other respects. On an average the treatment was completed on the twelfth day and the fifteenth day in actively treated cases admitted with temperatures respectively below and above 100.4°; on the tenth and fourteenth days after expectant or conservative treatment. Parametritis, adrenal inflammatory tumour, exudate in the pouch of Douglas, thrombophlebitis, or other grave septic complication appeared in 15.4 per cent. (admission temperature below 100.4°) and 24.5 per cent. (admission temperature above 100.4°) of cases treated actively, but in the corresponding groups of those treated by expectant or conservative methods, in 5.3 per cent. and 14.7 per cent. only. In accordance with this diminished morbidity the mortality was nil among the cases admitted with a temperature below 100.4° and treated conservatively or expectantly, and 2.4 per cent. only among those who after admission with a temperature exceeding 100.4° were similarly treated, whereas operative treatment given during the febrile stage was followed by a mortality of 3.5 per cent. and 4.8 per cent. in the respective groups. Conservative and expectant treatment have, of course, the additional advantage that there is some possibility of a case of threatened abortion continuing to term; this is stated to have happened in six cases of this series.

468 Missed Abortion.

LITZENBLAT (*Amr. Journ. of Obstet. and Gynec.*, February, 1921) considers missed abortion to be a condition which is frequently overlooked. This is of very great importance in medico-legal cases where a woman is not living with her husband. The author quotes Matthews Duncan, who said that this condition illustrated the fact "that if you do not know of a thing, you are quite sure not to suspect it; and if you do not suspect a thing, you are almost certain not to find it." The author points out that, the trouble once having been suspected, the diagnosis will be made by careful measurements of the uterus at an interval of a month or six weeks.

469. Syphilitic Placentae.

MANDUELIN (*Gynec. et Obstet.*, vol. iii, 1921) asks the question, "Why are spirochaetes so seldom found in the placenta of a syphilitic foetus?" He quotes many authors who have occasionally demonstrated them in the vessels and other parts of the chorionic villi, but who have had negative results even in the cases in which the liver and other organs have been crowded with spirochaetes. He considers that the answer to the question lies in the fact that a very intense phagocytosis exists in the placenta.

470. Successful Extirpation of Primary Tubal Cancer.

THALER (*La Gynéc.*, October, 1920) reported to the Vienna Gynecological Society two cases of primary carcinoma of the Fallopian tube. In striking contrast to the usual finding of speedy recurrence, the patients appeared to be cured at the end of three and a half and two years respectively. The first case was that of a multipara aged 40, who had pain and metrorrhagia, accompanied by pyrexia; the uterus was removed, together with the appendages, which were adherent to the intestine, and on the right side formed a partially cystic tumour, reaching to the umbilicus. A papillary carcinoma was found in the isthmus region of the right Fallopian tube. The second patient, a nullipara, suffered from post-climacteric bleeding, which was suspected to be due to sarcomatous transformation of a myoma. During the course of a vaginal hysterectomy the pouch of Douglas was found to be filled with carcinomatous masses extending from the right adnexa. A post-operative application of radium may have played some part in the apparent cure. Histologically the tubal growth in this case was an alveolar carcinoma.

471. Premature Births and Infantile Mortality.

FROM a consideration of the records of the Frauenklinik at Bremen, WIGGERS (*Zentralbl. f. Gynäk.*, March 5th, 1919) concludes that means for the reduction of infantile mortality due to prematurity or weakness at birth are to be found chiefly in (1) earlier and better treatment of parental syphilis; (2) restricted employment of induction of premature labour as a mode of terminating pregnancy in cases of contracted pelvis; (3) provision of institutions for care of foundlings and delicate children; (4) special medical care of premature children, carried out (in institutions) along lines which it should not be sought to standardize, but rather to adapt to the individual needs of different cases; (5) propaganda with regard to the importance of breast feeding. In the decennium 1909-18, of 4,532 births at the clinic, 548, or 11.9 per cent., were those of infants weighing less than 2,500 grams. The mothers of these were in 299 instances primiparae; in 207, multiparae.

PATHOLOGY.**472. Filtrable Bodies in Influenza.**

OLITSKY and GATES (*Journ. Amer. Med. Assoc.*, March 5th, 1921) give an account of the cultivation and appearances of certain minute bodies obtained from the filtered and unfiltered nasopharyngeal washings and lung tissues of patients suffering from epidemic influenza. The filtrates were cultivated in ascitic fluid containing a piece of rabbit's kidney, anaerobic conditions being maintained. About the fifth day a slight haziness was noted in the vicinity of the kidney tissue, but this became denser and progressed higher by the eighth day. After standing two weeks the cloudiness settled down and the fluid became clear. Film preparations from the bottom of the tube showed on staining with ripened alkaline methylene blue numerous minute bodies stained purple which were distinct from the precipitated granules of protein matter. These bodies have been observed in numerous primary cultures and in several hundred subcultures for as many as seventeen generations. They are comparable to the globoid bodies found in poliomyelitis, and are from 0.15 to 0.3 micron in length, being twice or three times as long as broad. They often occur discretely, sometimes in groups of two or three, and sometimes in clumps. The clumps range in size from that of a blood platelet to that of a polymorphonuclear leucocyte. They are decolorized by Gram's method. These bodies are destroyed by heating to 56° C. for half an hour. The cultivated bodies pass through V and N Berkefeld filters, and remain alive in sterile 50 per cent. glycerin for several months. They have been recovered from the lung tissues of animals injected with influenzal nasal secretion. When the cultures are injected intratracheally into rabbits and guinea-pigs there is a rise of temperature, conjunctivitis, and leucopenia after twenty-four to forty-eight hours, a condition which lasts for one to three days.

473. Lymphoid Cells in the Blood in Acute Leukaemia.

JOLLY and LAVEDAN (*C. R. Soc. Biologie*, January 22nd, 1921) recommend the use of wet preparations in the study of abnormal blood corpuscles. They are accustomed to plunge the freshly spread slide at once into a fixative

solution. Their favourite fixative is a mixture of 30 volumes of 1 per cent. chromic acid, 10 volumes of 1 per cent. osmic acid, and a drop of acetic acid: the slide is fixed for two or three minutes, washed in running water, and stained with eosin-orange-toluidin. Such a technique is indicated where nucleated red corpuscles are present and in the study of leukaemic blood. The authors refer to a case of acute leukaemia in which there were about 600,000 leucocytes per cubic millimetre, all corresponding to an indifferent type of lymphoid cell with a large nucleus, which has been called by different writers, according to the theoretical idea held by them, lymphocytes, leucoblasts, or myeloblasts. In films dried and stained by the usual methods these cells are large, with enormous nuclei showing no clear chromatic network, with no visible membrane, slightly basophile protoplasm, numerous degenerate forms, but no mitotic figures. By the technique already mentioned, however, these cells appear much smaller, only a little larger than the red corpuscles and the small lymphocytes; their nuclei are very large and limited by a very distinct membrane; two or three characteristic nucleoli may be found; the chromatic network is not well developed, but is sometimes clearly visible though extremely fine; no degenerate forms are to be seen; and mitoses, though not numerous, can easily be found. In addition to these elements there exist true myeloblasts of larger size in which the protoplasm is definitely basophile, some lymphocytes, leucocytes, myelocytes, and occasional nucleated red cells. The lymphoid cell here described is difficult to place; it is indifferent, and cannot with certainty be classified as coming from the bone marrow or the lymphatic system. Probably we should not separate these two great classes of white cells as distinctly as has hitherto been the custom.

474. Intradermo and Subcutaneous Reactions in Hydatid Disease.

PONTARO (*Il Policlinico*, Sez. Med., November 1st, 1920), as the result of his researches, has come to the following conclusions: (1) The fluid of hydatid cysts has an antigenic value for the human organism. Experimentally it is possible to sensitize an individual who is not suffering from the disease, and to confer on the serum the property of fixation of the complement by successive inoculations of hydatid fluid. (2) Intradermic and subcutaneous inoculation of freshly withdrawn cyst fluid produces local reactions (Casoni's intradermo reaction and subcutaneous reaction) in patients with hydatid disease. (3) The doses suitable for the specific reaction are 0.20 to 0.30 c.cm. for the intradermo reaction, and 1 c.cm. for the subcutaneous reaction. (4) The cutaneous reactions are positive in a very high percentage of cases of hydatid disease in which the cysts are not suppurating; when the cysts are suppurating the percentage is very low. (5) The cutaneous reactions are quite as specific as the Ghedini-Woinberg reaction, but are more delicate and simpler to perform. (6) Attempts to produce a state of anaphylaxis in patients with hydatid disease by injections of vaccine have not hitherto been successful.

475. Blood Changes in Lead Workers.

SELLERS (*Journ. of Indust. Hygiene*, February, 1921) records observations upon the changes in the blood in men who had been exposed to lead for a fairly long time. Blood taken from the ear or finger was examined for red and white cell count, haemoglobin estimation, and in films stained by Leishman's stain and methylene blue. In a very large proportion of cases there was found to be a diminution of haemoglobin and punctate red cells were present. The latter were frequently, though not constantly, found in men giving a history of blue line on the gums. Such punctate red cells were found very rarely and in very small numbers in healthy persons, and, though they occur in other diseases and cases of poisoning by other agents than lead, it is usually easy to recognize a film from a lead worker because of their presence in comparative number. The corpuscles containing the granules appear sometimes slightly larger than normal, and show an increased affinity for the blue stain. The granules are situated mostly in the periphery of the corpuscle. Further observations have shown that as a means of diagnosis and for the control of lead workers such blood examinations are unreliable as they do not afford a definite criterion one way or the other, since some cases of lead poisoning show no changes in the blood, and also definite changes may be present without any other sign of the disease. A blood examination, therefore, in a suspected case must be regarded as only one of many other pieces of evidence towards arriving at a diagnosis.

"Iodolysin"

IN RHEUMATISM &
RHEUMATOID
 ARTHRITIS

'Iodolysin' is a soluble compound of Thiosinamin with Iodine and contains 43 per cent. Thiosinamin and 47 per cent. of Iodine. The preparation has been very successfully used in the treatment of Rheumatoid Arthritis and Arthritis Deformans.

A Striking Report

'It may interest you to know that I have been using it ('Kapsol' 'Iodolysin') in a case of Rheumatoid Arthritis with very marked success. I saw the case first about a year ago when she had been a complete cripple for over six months. She was discharged from a hospital in ——— as incurable. I found her suffering from *pyorrhea alveolaris*, which I treated with an auto-vaccine and afterwards gave her the 'Iodolysin,' and that only, in varying doses. She can now walk into her garden, goes up and down stairs, dresses her own hair, and her joints are quite free from pain and deformity. She continues to take one 'Kapsol' daily. I think the result is most satisfactory.'

The Super-Milk

is a galactagogue of proven value

Extract from the Annual Report upon Maternity and Child Welfare by the County Medical Officer for Monmouthshire, 1919:

"Many of the mothers have a good quantity of milk, but it is of poor quality. This is almost invariably remedied by the addition of Glaxo to the mother's diet, an addition which the majority of mothers declare improves their milk from the first day they take it."

Remarks

ON

POSTURAL OR SO-CALLED STATIC DEFORMITIES.

BY

A. S. BLUNDELL BANKART, M.Ch.CANTAB.,
F.R.C.S. ENG.ORTHOPAEDIC SURGEON, MIDDLESEX HOSPITAL; SURGEON, ROYAL
NATIONAL ORTHOPAEDIC HOSPITAL AND HOSPITAL FOR EPILEPSY
AND PARALYSIS, MAIDA VALL.

I.

Static deformities have been defined as those which are due in the main to the action of gravity. But, as everyone is subject to the action of gravity, it is clear that this is not enough in itself to account for deformity in an otherwise normal person. It would be more correct to say that static deformities are due to default of the normal mechanism for counteracting the influence of gravity and maintaining the body in the upright position. This mechanism is a nervous mechanism, for it has been shown by Sherrington¹ that the upright attitude or posture of the body is maintained by continuous reflex muscular activity (postural activity). For this reason I prefer to speak of these deformities as postural rather than static. The word static implies something almost wholly mechanical, whereas I believe that many of these deformities are really nervous in origin.

I must say, however, that by postural deformity is meant not merely a faulty posture as such, but also the deformity that may develop from it. This is important, because many writers have tried to draw a distinction between postural deformity and structural deformity, holding that a deformity is no longer postural when structural changes have taken place in it. Such a distinction is wholly artificial and misleading. A rachitic deformity is still a rachitic deformity after the active rickets has subsided. A paralytic deformity is a paralytic deformity even though the paralysis has recovered. Similarly, a postural deformity is one that begins as a faulty posture and passes through all degrees up to severe structural alteration.

GENERAL CONSIDERATIONS.

In the skeletal muscles we meet with two kinds of muscular activity. The one is phasic—quick and transitory and concerned with the execution of movement; the other is tonic—relatively slow and prolonged and concerned with the maintenance of posture. These two kinds of activity are quite distinct. Indeed, in certain invertebrates there are separate muscles, differing in structure and in appearance, for the execution of movement and for the maintenance of posture respectively. In vertebrates the same muscle is utilized for both purposes, but there is reason to believe that different parts of the muscle fibres are concerned in these two functions. It has been suggested by Bottazzi² and others that the sarcostyles constitute the contractile or movement mechanism, and the sarcoplasm the tonic or posture mechanism. Further, there is some evidence that these two mechanisms have independent nerve supplies, and that the sympathetic may be concerned in the tonic or postural contraction of voluntary muscle. Perroncito³ and Boeke⁴ have described accessory (sympathetic) nerve endings in voluntary muscles. These consist of fine non-medullated nerve fibres connected with the perivascular sympathetic nerve plexus and terminating in the sarcoplasm independently of the motor end plate. De Boer⁵ was able to abolish the tonic or postural contraction in the hind limbs of the frog and cat by section of the rami communicantes of the sympathetic.
